SUPPLEMENT

TO THE

CYCLOPÆDIA,

OR,

UNIVERSAL DICTIONARY

OF

ARTS AND SCIENCES.

M.

MABBY, a kind of wine made from potatoes. It is faid to be ufed in Barbadoes. *Boyle*'s Works abridg. vol. 1. p. 71.

MABOUJAS, the *devil lizard*, a fpecies of American lizard, fo called from its uglinefs and difagreeable afpect. It grows to fix or feven inches long, and to the thicknefs of a thumb, and is found in the trunks of rotten trees, and in marfhy places, where the fun beams feldom reach. It is all over of a gloffy black colour, and looks as if fmeared over with oil. *Rochefort*'s Hift. Antill.

MACAM, *Indian apple*, in natural hiftory, the name of a common Eaft-Indian fruit; it is of a round fhape, and about the fize of our common wild crabs which grow in the hedges. Inftead of the feveral fmall feeds which our crabs and apples contain, this fruit has only one hard kernel. It is of an acid tafte, and of a raw and not very agreeable fmell. The tree which produces this fruit, does not grow to any great height It refembles the quince tree in its leaves, except that they have a yellowifh caft. Mem. Acad. Par. 1699.

MACAQUO, in zoology, the name of a large fpecies of monkey, called by Mr. Ray *cercopithecus angolenfis major*, the great Angola monkey. Its hair is all of the colour of that of a wolf, its noftrils are elate, its head like a bear's, and its buttocks are bald, on thefe he frequently fits upright. He always carries his tail bent into a fort of arch, his length from the head to the infertion of the tail is more than a foot; his tail equals his body in length, his legs are confiderably long, and his body remarkably fat and bulky; his teeth are extremely white, and his penis very much refembles that of a man. It is an extremely lively animal, and continually plays a number of antic tricks; its voice is fhrill, and its only note hah! hah! *Ray*'s Syn. Quad. p. 155. See CERCOPITHECUS.

They have another fpecies of this kind alfo about Angola, which may be called the black *Macaquo*. Its only colour is black, but on many parts of the back and fides, there is a greyifh caft among it. This has a tail of remarkable length, being more than two foot long.

MACARON, the name of a fort of vermicelli, a pafte made of flour and water, and formed into the fhape of the barrel of a large quill, or the guts of fmall fowls.

MACAW, or MACAO, in zoology, the name of a large fpecies of parrot, diftinguifhed alfo by the length of its tail. There are three different fpecies of this bird brought over into Europe, which not only differ in fize and other particulars, but alfo in colour. The firft is the largeft, and is finely variegated with blue and yellow. The fecond is fomewhat fmaller than this, and is principally red and yellow, and the third is red and blue. It is not uncommon alfo to fee the *Macaw* perfectly white, and it is to that particular colour we give the name of *cockatoon*; though with fome it is made the fynonymous name of all the *Macaw* tribe.

MACERONE, in botany, a name given by fome authors to the great *hippofelinum*, or herb Alexanders. *J. Bauhine*, vol. 3. p. 126.

MACHÆRION, a word ufed by chirurgical writers as the name of an inftrument of the nature of the incifion knife. It is alfo fometimes ufed to exprefs an incifion, and by the arufpices of old it was applied to fome peculiar part of the liver of animals, from which they prefaged events.

MACHERA *Lapis*, in natural hiftory, the name of a ftone of a ferrugineous colour, frequent on mount Berecynthus in Phrygia. Plutarch, and many other grave writers, relate, that if any perfon found this ftone, and took it up at the time of the celebration of the feafts of Cybele, he inftantly was feized with madnefs.

MACHLIS, in natural hiftory, a name ufed by Pliny and fome of the old authors, for the rein-deer. See the article RANGIFER.

MACKREL, the Englifh name for the fcombrus, or fcomber. See the article SCOMBER.

Horfe MACKREL. See the article HORSE-*Mackrel*.

MACROCELE. See the article FULICA.

MACROCEPHALUS (*Cycl.*)—*Macrofephali*, or *Long heads*, is a name given to a certain people who, according to the accounts of authors, were famous for the unfeemly length of their heads; yet cuftom fo far habituated them to it, that inftead of looking on it as a deformity, they efteemed it a beauty, and as foon as the child was born, moulded and fafhioned its head in their hands to as great a length as poffible, and afterwards ufed all fuch rollers and bandages as might feem moft likely to determine its growing long.

MACROCERCOS *Ovis*, in natural hiftory, the name of a fpecies of fheep fomewhat allied to the *ovis laticauda*, or *platycercos* in the largenefs of its tail; but as that extends fo wonderfully in breadth, this does fo no lefs in length, being defcribed to be three cubits long.

Authors who have treated of this animal obferve, that it is wholly unable to manage this load of tail, fo that in the

natural state it trails upon the ground, and soon becomes sore and ulcerated; for this reason the shepherds are obliged to contrive a sort of support for it, by which the animal is made easy.

MACROCOLUM, or MACROCOLLUM, among the Romans, the largest kind of paper then in use. It measured sixteen inches, and frequently two feet.

MACROLOGY, Μακρολογία, in rhetoric, a redundant, or too copious stile; an example of which we have in Livy, lib. viii. *Legati non impetratâ pace, retro domum, undè venerant abierunt.*

The too copious is equally subject to obscurity with the two concise stile, and consequently ought to be avoided. *Voss.* Rhet. l. 4. c. 1. §. 12. p. 35. See the articles BRACHYLOGY and DICTION.

MACROPEDIUM, the *Long-legs*, a name given by some writers in natural history, to the common tipula. See the article TIPULA.

MACROPIPER, a name given by authors to the *piper longum*, or long pepper.

MACROPNUS, a word used by Hippocrates and other old writers in medicine, to signify a person who fetches his breath at long intervals. It is used in opposition to *brachypnus*, or short-breathed. See the article BRACHYPNÆA.

MACROPTERA, in zoology, the name of a genus of birds of the hawk kind, remarkable for the length of their wings. The word is derived from the Greek μακρὸς, long, and πτερὸν, a wing.

The hawks of this genus have their wings so long, that when closed they reach to the end of the tail, or nearly so. Of this genus are the bald buzzard, the kite, the hen harrier, the honey buzzard, and common buzzard, the sacre, the jersalcon, &c. *Willughby*'s Ornitholog. p. 40.

MACRORYNCHÆ, *long-beaked*, in the Linnæan system of zoology, the character of a large order of the bird kind.

The word is derived from the Greek μακρὸς, long, and ῥύγχος, a beak

The birds of this order have all of them beaks many times longer than their head, with oblong nostrils, and a furrow running from them towards the apex of the beak. *Linnæi* System. Nat. p. 45.

MACROTELOSTYLA, in natural history, the name of a genus of crystals, which are composed of two pyramids joined to the end of a column, both the pyramids, as also the column, being hexangular, and the whole body consequently composed of eighteen planes.

The word is derived from the Greek μακρὸς, long, τέλειος, perfect, and στύλος, a column; expressing a perfect crystal with a long column. See Tab. of Fossils, Class 3.

There are only three known species of this genus: 1. A very bright and colourless one, found in some few places in England, and very common in the mountains of Germany. 2. A blackish very bright kind, with short pyramids, found sometimes in Cornwall, but more frequent in Italy. And, 3. A dull whitish one, with irregular pyramids; this is sometimes found in Yorkshire and in Cornwall, and is very common in Germany. Either of the sorts found with us, are called by the common name of *Cornish diamonds*. *Hill*'s Hist. of Foss.

MACROULE, in zoology, the name given by many to the largest species of coot. It is of a deeper black than the common kind, and has a larger bald spot on its head. It is also called by some *diable de mer*. *Ray*'s Ornithol. p. 289. See the article FULICA.

MACUCAQUA, in zoology, the name of a Brasilian bird of the gallinaceous kind, called also by some the *gallina sylvestris*, or wild hen. It is larger than our common hen, and has a black strong beak somewhat hooked at the end; its body is thick and bulky, and it has no tail; its head and neck are variegated with black and yellow spots, its throat is white, its breast, belly, and back, are of a dusky ash-colour; its wings are of an olive colour, and are variegated with black; the long feathers of them are all black. It is a very well-tasted fowl, and has twice as much flesh as the European hen; its eggs are somewhat larger than the common hen egg, and of a bluish-green colour; it feeds on fruits that fall off the trees, &c. and runs well, but cannot fly high or far, and never is seen in the trees. *Marggrave*'s Hist. Brasil.

MACULA, (*Cycl.*) in the writers of medicine, is used to express all kinds of spots and efflorescences on the skin with different epithets. Thus *Maculæ pestilentiales* are the spots or efflorescences which appear upon the skin in pestilential diseases. *Maculæ hepaticæ* are spots of a brownish red colour appearing on the skin in many places, from an *ichorescence* of the blood, attended with a sort of coagulation. *Maculæ volaticæ*, or vanishing spots, are very common to children, appearing in several parts of their bodies, and very soon disappearing again. *Maculæ maternæ* are the spots or blemishes on children called *nævi*, and marks from the mother's longing; and *maculæ albæ* are white spots which appear in the cornea of the eye, called by other names, albugo, leucoma, nebula, and nubecula.

MACULA *Oculi*, a word used by many authors to signify a cataract or suffusion.

MAD-*Dog*. See the article MADNESS.

MAD-*Apple*. See the article MELONGENA.

MADAROSIS, a word appropriated by the Greek physicians to the falling off of the hair of the eye-lids. This was usually occasioned among them by small but foul ulcers on the verge of the eyelid, and this falling off of the hair about their edges, is said by Hippocrates to have been a very bad symptom.

MADDER (*Cycl.*)—For the botanical characters of *Madder*, See the article RUBIA.

The culture of *Madder* is an article of considerable advantage to the Dutch, and might be prosecuted here with equal success. The method of cultivating it in Holland is this: In autumn they plough the land where the *Madder* is to be planted, laying it up in high ridges, that it may be mellowed by the winter's frosts. In March they plough it again, working it very deep, and laying it in ridges at eighteen inches asunder, and about a foot deep. Then, in the beginning of April, when the *Madder* begins to shoot out of the ground, they open the earth about the old roots, and take off all the side shoots, which extend themselves horizontally just under the surface of the ground, preserving as much of the root as may be with them. These they plant immediately on the tops of the new ridges, at about a foot distance from each other; and this they usually do in showery weather, when the plants immediately take root, and require no more water. In these ridges they let the plants remain two seasons, keeping them clear of weeds; and at Michaelmas time, when the leaves are fallen off, they take up the roots, and dry them for the market.

In England it would not be necessary to lay the ground up in ridges, as our lands are not so subject to over-flowings; the plants also will thrive better, if at greater distances, and if the horizontal roots were to be destroyed at times, the downright root would succeed much the better. *Miller*'s Gardener's Dict.

MADDER-*Root*. Mr. John Belchier shewed to the Royal Society the bones of hogs which were become red, by their feeding on bran that had been boiled with printed calicoes, which had been stained with preparations of iron, alum, sugar of lead, and had had an infusion of *Madder-root*, to fix the colours. By feeding a cock sixteen days on fig-dust, with a little *Madder-root*, all his bones became also red. Phil. Trans. N° 457.

Mr. Hamel du Monçeau verified Mr. Belchier's experiments, and observed, that except the villous coat of the stomach and intestines, the capsula of the crystalline and vitreous humours of the eyes, and some very hard bony tendons, and the bones, no other part had any tincture of the *Madder*. The most solid bones were most tinged, and all the red ones were larger, more spongy, and easily broken; nor did they unite so well, when broken, as white bones. Some young animals had their bones tinged in three days. The red colour went gradually off, when the creatures forbore to take the *Madder* for food, which proved unhealthy, for they began to languish soon, and died with it.—Vegetables did not take the red colour when they were planted in *Madder*; and none of the other dyes, with which he fed animals, had any such effect of tinging their bones, as the *Madder* had. Mr. du Hamel, having mixed *Madder* with the food of a pig for some time, and then kept away the *madder* an equal time, found, upon sawing the bones through, that their interior laminæ were red, while the exterior were white: And having fed another pig six weeks with *Madder*, then kept it out of its food as long, and then mixed it other six weeks; upon sawing the bones, they were composed of three layers, the external and internal were red, the middle one was white. Mem. de L'Acad. des Scienc. 1739. & Phil. Trans. N°. 457, §. 4. Med. Ess. Edinb. Abr. Vol. 2. p. 477.

MADELION, in the materia medica, a word used by Dioscorides for *bdellium*.

MADERAM-*Pulli*, in botany, a name used by some authors for the tree whose fruit is the tamarind of the shops. Hort. Malab. vol. 1. p. 39.

MADIC, a word used by some medical writers for buttermilk.

MADISTERIUM, a name given by the Greeks to an instrument intended to keep the skin smooth, by eradicating the hairs.

MADNESS, *Mania*, in medicine. See the article MANIA, *Cycl.* and *Suppl.*

MADNESS *from the bite of enraged animals, Rabies canina.*—The bites of enraged animals, tho' they were not *mad* at the time they inflicted them, are usually attended with very grievous consequences. If the wound is slight, the discharge of blood from the part is to be encouraged by pressing it with the fingers, sucking it in the mouth, or by the application of cupping-glasses, or enlarging it with a lancet. It is afterwards to be washed with warm spirit of wine, and bolsters dipped in the same liquor, are to be applied to it, repeating the application every three or four hours, till all danger of inflammation is gone off. If the wound be considerably deep, it is always necessary to enlarge it with the knife, unless it have already a very large opening; and, after applying spirit of wine for the first days, to prevent the bad symptoms, it may be easily healed with honey, or some digestive ointment, and afterwards with a vulnerary balsam, as usual in other wounds. *Heister*'s Surg. 97.

To know whether the dog which has bitten a person be or be not *mad*, it is necessary to know the marks by which a dog, in that condition, is to be distinguished from others; these are, that he foams at the mouth, lolls out his tongue, claps his tail between his legs, and runs up and down, without ceasing, as if he was pursued; he makes a hoarse noise when he barks, and is afraid of all animals that come in his way, snapping at every thing he meets, even his master whom he used to fawn upon; and other dogs are afraid of him, and avoid him.

Persons bit by a *mad* dog are usually afflicted with very violent disorders, sometimes sooner, sometimes later, according to the malignity of the poison imbibed by the wound, and other accidents. The most proper thing the surgeon can do on this occasion, is to enlarge the wound with the knife, and promote the flowing out of the blood; then to wash it with salt water, or with Venice-treacle dissolved in vinegar; and when the texture of the part will permit, that is, when only the common integuments, or fleshy parts are wounded, to apply the actual cautery to the wound, and afterwards dress it as other burns. Another method much practised, is to make a tight ligature above the wound, to prevent, as much as may be, the return of the blood by the veins from that part; then to enlarge the wound with a knife, and wash it as before directed; then cauterize it if the part will admit that operation, if not, cleanse the wound, if deep, by means of a syringe, and apply over it a plaster of the mercurial kind; and if the person be plethoric, to open a vein. After the Venice-treacle has been used for a day or two in these cases, the wound is to be dressed with honey, or with the common digestive ointment, mixed with the Ægyptian ointment, or with red precipitate, and be kept open by means of these dressings for some weeks; for wounds of this kind must never be healed too soon, especially when they have not been cauterized. *Heister*'s Surg. 99.

Dr. de Sault argues for the *rabies canina*, depending on small worms, of which, he says, there are a great number found in the heads of those who die of this disease. From the analogy of this terrible disease with others; such as the itch, lues venerea, &c. which, in his opinion, are also contagious, by worms communicated from one person to another, he was led to think that the cure of the *rabies* was only to be performed by mercury, and the success confirmed his theory; for of four men who had all been bit at the same time by the same wolf, two were treated by the common specifics of plunging in the sea, &c. and died some days after of the *rabies*. The other two, having all the signs of an approaching *rabies*, were cured by Mr. de Sault's method, which is this: If he is consulted immediately after the person is bit, he orders him to be bathed in the sea, that the common confidence in this method may calm his mind. As soon as the patient returns, he puts him on the use of Palmarius's powder, composed of Fol. Rut. Verben. Salv. Plantag. Polypod. Absinth. Vulg. Menth. Artemis. Meliss. Betonic. Hyperic. Centaur. Min. ana partes æquales, with some coralline. A dram of this powder is to be taken every morning, in a glass of white wine or warm water. This he gives for twenty or thirty days, as there is more or less presumption of the poison having entered the blood. From the first day of taking the powder, he rubs a dram or two of ung. Neapolit. upon the wound, and skin round it, every other day. After doing this thrice, he applies the ointment every third day; and afterwards every fourth day, till he has made use of two or three ounces of the ointment. If the patient has delayed several days to take his advice, he uses the mercurial friction three or four times a day, for four days, and encreases the dose of Palmarius's powder; then forbears the inunction two days, lest a salivation should be brought on. Our author likewise recommends music as of use to calm the mind, and divert the fear which people, in danger of this disease, generally have. Medic. Ess. Edinb.

Dr. James relates the cure he made of dogs that were *mad*, and how he preserved others from the rabies, who had been bit by *mad* dogs, by giving doses of turbith mineral every day, or every other day. The other dogs of the pack that had been bit, died, notwithstanding the famous pewter medicine, dipping in the sea, and the other common specifics. The Doctor likewise mentions three people who were bit by *mad* dogs, and escaped the *rabies* by the use of the turbith. Phil. Trans. N°. 441. §. 8.

Mr. Fuller relates the good effects of the pulvis antylissus, composed of lichen. ciner. terrest. and piper. nigr. a a. in preventing the *rabies*. Phil. Trans. N°. 448. §. 5.

A person who had been bit by a *mad* dog, and began to have symptoms of the *rabies*, was saved by having one hundred and twenty ounces of blood taken in a week, and being bathed in cold water. Phil. Trans. ibid. §. 6.

Mr. Nourse relates the history of a lad bit in the thumb by a *mad* dog; he took morning and evening a dram of the *pulvis antilyssus* forty days, and bathed in the sea ten days; he was cut for the stone soon after, and recovered very well; nineteen months after which he died, with all the symptoms of the hydrophobia. Phil. Trans. N°. 445. See the article HYDROPHOBIA.

We have an account of a man bit by one of these animals; who was cured by bleeding, nitre, and mithridate. See Phil. Trans. N°. 475. Sect. 4. The *pulvis antilyssus*; and cold bathing, far from alleviating the symptoms in this patient, rather increased them. The cold bath was observed to augment the head-ach. Dr. Mortimer, the editor of the transactions, proposes warm bathing.

The Tonquinese pretend to an infallible remedy for the bite of the *mad* dog. Their method is to take about sixteen grains of the best musk; of the purest native cinnabar, and finest vermillion, each about twenty four grains; and having reduced them separately to impalpable powders, they mix and administer them in about a gill of arrack. This, in two or three hours, generally throws the patient into a sound sleep, and perspiration: If not, they repeat the dose, and think the cure certain. See Phil. Trans. N°. 474. p. 225. seq. Where Mr. Reid, to whom we are obliged for this receipt, observes, as to the vermillion, that though it be a preparation of cinnabar, yet, as the Tonquinese seem to think its virtue different, it were to be wished, that we knew their method of preparing it, in which they certainly excel.

This composition of musk and cinnabar has been applied with success to other distempers, only as Tonquin vermillion is not easy to be had, Mr. Reid substituted an equal quantity of factitious cinnabar in its stead, and sometimes administered it in rum or brandy instead of arrack. See the article MUSK.

MADNING-*Money*, old Roman coins, found about Dunstable, are so called by the country-people; and have their name from *magintum*, used by the emperor Antoninus in his Dunstable itinerary. *Camb. Blount.*

MADON, in botany, a name by which Pliny, and some other authors, have called the white bryony. *Ger.* Emac. Ind. 2.

MADOR, a word used by some authors to express the sweat which arises under a syncope or fainting, whether it be cold or hot, or in larger or smaller quantities.

MADREPORA, in botany, the name of a genus of sea plants, the characters of which are, that they are almost of a stony hardness, resembling the corals, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure.

The species of *Madrepora*, enumerated by Mr. Tournefort, are these: 1. The starry *Madrepora*. 2. The branched *Madrepora*. 3. The *Madrepora*, commonly called *Millepora*. 4. The common white oculated *Madrepora*, called the oculated white coral. 5. The small white stellated and verrucose *Madrepora*, called the coralloide porus, and the astroites. 6. The much branched, and elegantly stellated white *Madrepora*. 7. The punctated verrucose *Madrepora*. 8. The abrotanum-like *Madrepora*. 9. The branched erect *Madrepora*, with numerous tubercles bending upwards. 10. The white compressed *Madrepora*, of a foliaceous structure, and sieve-like texture. 11. The white cypress-like *Madrepora*, or white porus, with hollow tubercles. 12. The great tree *Madrepora*. *Tourn.* Inst. p. 573.

MAEL *Coronde*, in the language of the Ceylonese, the flowering cinnamon tree. This is a name given to a peculiar species of the cinnamon tree, which is all the year round found full of flowers. The flowers are not easily to be distinguished from the very finest cinnamon flowers, but they produce no fruit, which the flowers of the fine cinnamon always do. The bark is much like that of the best cinnamon, in external appearance; but it has very little taste or smell. The tree grows very large, and the inhabitants sometimes tap it, by boring a hole into the trunk, at which it bleeds a thin watery juice, in the manner of our birch tree.

MÆMACTERION, Μαιμακτηριών, in chronology, the fourth month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our September and beginning of October. The Bœotions called it *Alalcomenius*.

It took its name from the festival *Mæmacterica*, sacred to Jupiter, kept at this time. See *Pott.* Archæol. Græc. l. 2. c. 20. Tom. I. p. 413.

MÆMACYLON, in the materia medica, a name given by Dioscorides, and the antients in general, to the fruit of the Arbutus, or strawberry-tree.

MÆNA, in zoology, the name of a small fish, caught in vast abundance about the shores of the Mediterranean, and common in the markets of Italy, where they are accounted but a poor sort of fish, and sold at a very cheap rate. It is somewhat of the figure of the pearch, but broader and thinner, and is seldom above four or five inches in length. Its colour is a dusky pale green, and pale yellow, variegated with transverse black lines, and some longitudinal ones of a fine blue; and on each side, near the middle of the body, and just below the line which runs from the gills to the tail, it has a large black spot. This fish changes its colour in the different seasons of the year, being white in winter, and greenish, or yellowish, and streaked and spotted in the summer. The eyes are large, and the tail not much forked. Its back fin has the anterior rays prickly, the rest smooth. *Rondelet.* de Pisc. l. 5. c. 13. p. 138. *Aldrovand.* de Pisc. l. 2. c. 39. p. 223. *Gesner.* de Pisc. p. 612.

MÆNA *Candida*, in ichthyology, a name given by many authors to the smaris. It is not very improper, for they are

both of the fame genus of the fparus, and are very nearly allied to one another; the principal difference confifting in the tail and belly fins of the fmaris being red. See the articles MÆNA and SPARUS.

MAESTOSO, or MAESTUOSO, in the Italian mufic, fignifies to play with grandeur, and confequently flow, but yet with ftrength and firmnefs.

MAFORTIUM, among the Romans, a veil, or head-drefs, worn by the married women. *Pitifc.* in voc.

MAGAS, in the antient mufic, is ufed to denote the bridge of any inftrument.

MAGAURI, in zoology, the name of a Brafilian bird, a fpecies of ftork. It is of the fize of the common white ftork. Its neck is a foot long, and its beak ftrait and pointed, and nine fingers breadth in length; its legs long and naked. Its tail is fhort. Its head, neck, and body, are covered with fnow-white feathers. On the throat thefe are very long, very white and valuable. Its wing and tail have their long feathers black. Its legs are red; and its flefh eatable. *Marggrave*'s Hift. Brafil.

MAGBOTE, or MÆGBOTE, in our old writers, a compenfation for the flaying or murder of one's kinfman, in antient times, when corporal punifhments for murder, &c. were fometimes commuted into pecuniary fines, if the friends and relations of the party killed were fo fatisfied. Leg. Canuti, cap. 2. *Blount*, Terms of Law.

The word comes from the Saxon *Mæg*, i. e. *Cognatus*, and *Bote*, *Compenfatio*.

MAGDALEO, a word ufed by difpenfatory writers, to exprefs any thing made up into a cylindric form. The common rolls of plafters which the apothecaries make up, to be ready for fpreading upon occafion, are thus called, as alfo the rolls of fulphur, or common brimftone.

MAGDALIÆ, or MAGDALIDES, the fame as *Magdaleones*, rolls of fulphur, plafters, &c. Vid. fupra.

MAGELLANIC *Clouds*, whitifh appearances like clouds, feen in the heavens towards the fouth pole, and having the fame apparent motion as the ftars.

They are three in number, two of them near each other. The largeft lies far from the fouth pole; but the other two are not many degrees more remote from it than the neareft confpicuous ftar, that is, about eleven degrees.

Mr. Boyle conjectures, that if thefe clouds were feen thro' a good telefcope, they would appear to be multitudes of fmall ftars, like the milky way. *Boyle*'s Works abr. vol. 1. p 295.

MAGELLANIC *Goofe*, *Anfer Magellanicus*, in zoology. See the article GOOSE.

MAGGOT, the common name of the fly-worm, bred in flefh, from the egg of the great blue flefh-fly Notwithftanding the diftafte for this animal, its figure, and ftructure of parts is greatly worth attending to, and may ferve as a general hiftory of the clafs of worms produced from the eggs of flies.

This animal is white and flefhy; its body is compofed of a number of rings, like the bodies of caterpillars, and other the like infects, and is capable, at the pleafure of the animal, of affuming different figures, being, at times, more or lefs extended in length, and confequently more or lefs thick.

Notwithftanding that this creature has no legs, it is able to move itfelf very fwiftly, and, in its firft attempt to move its body, is extended to its greateft length, and affumes fomething of the figure of a pointed cone. The pointed part of this cone is the head of the animal, and is not feparated from the next ring by any deeper furrow than the reft of the rings are from one another. In fome ftates of the animal, one may fee two fhort horns thruft out from the head; but what are more conftantly obfervable are two brown fealy hooks; thefe are, however, fometimes hid, and have each of them a fheath, or cafe, into which the animal can retract them at pleafure. Thefe hooks are bent into an arch, the concavity of which is toward the plane on which the creature is placed, and they are thickeft at their infertion in the head, and thence diminifh gradually, till they terminate in a fine fharp point.

Thefe two hooks are placed in a parallel direction, and can never come together, and therefore cannot ferve in the place of teeth to grind the food between, but merely to pull and fever it to pieces, that it may be of a proper fize for the mouth of the creature.

The creature has befide thefe two hooks a kind of dart, which is of about a third part of their length, and is placed at an equal diftance between them. This alfo is brown like them, and fealy; it is quite ftrait, and terminates in a fine point. The hooks have, as it were, two fealy thorns at their points, and this dart feems intended, by reiterated ftrokes, to divide and break the pieces of flefh thefe have feparated from the reft into fmaller parts.

Immediately below the apertures for the egrefs of the hooks, is placed the mouth of the animal; the creature does not fhew this little opening unlefs preffed, but if the preffure be properly managed, it will fufficiently open it, and there may be difcovered within it a fmall protuberance, which may very naturally be fuppofed either the tongue, or the fucker of the animal.

The hooks in thefe creatures not only fupply the place of teeth, but alfo of legs, fince it is by faftening thefe hooks into the fubftance it is placed on, and then drawing up its body to it, that it pulls itfelf along.

The back of this creature lowers itfelf by degrees as it approaches the extremity of the belly, and near the place where the back begins to lower itfelf, are placed the creature's two principal organs of refpiration. One may perceive there two fmall roundifh brown fpots; thefe are very eafily diftinguifhable by the naked eye, becaufe the reft of the body of the creature is white; but if we take in the affiftance of glaffes, each of thefe fpots appears to be a brown circular eminence raifed a little above the reft of the body. On each of thefe fpots one may alfo difcover three oblong oval cavities, fomething of the fhape of button-holes; thefe are fituated in a parallel direction to one another, and their length nearly in a perpendicular direction to that of the body of the animal.

Thefe apertures are fo many ftigmata or air-holes, openings deftined to admit the air neceffary to the life of the animal. The creature has fix of thefe ftigmata, three in each fide of its body.

The great tranfparence of the body of this infect, gives us an opportunity alfo to diftinguifh that it has on each fide a large white veffel running the whole length of the body. It is eafy to follow the courfe of thefe veffels through their whole length, but they are moft diftinct of all toward its hinder part, and they are always feen to terminate each in the brown fpot before defcribed; this leaves us no room to doubt but that they are the two principal tracheæ.

Thefe pofterior tracheæ have been well known to the later naturalifts; but there are two others befides thefe which they feem not to have diftinguifhed. Thefe are fituated in the anterior part of the animal, and are eafily difcovered by following the courfe of the tracheæ on each fide; for though thefe all the way diminifh in their diameters as they approach the head of the animal, yet it may be eafily enough feen where they terminate, which is (taking the head for one ring) in the junction of the fecond and third ring. In this place the naked eye eafily difcovers a fmall fpot at the extremity of each, which viewed with a good microfcope appears to be a plain ftigma, of the figure of a funnel with half of it cut off, and very elegantly indented, and as it were fringed at the edges.

Thefe ftigmata in the anterior part of the body, are as conftant in this creature as the pofterior ones, but it feems to have none of thofe which the caterpillar clafs are furnifhed with along their fides; though it feems from the ftructure of the fly it afterwards transforms itfelf into, that it ought to have them, fince that has ftigmata in their places.

The ramifications of the two great tracheæ are very beautifully feen in this creature, efpecially on its belly; and it is remarkable, that no veffel analogous to the great artery in the caterpillar clafs can be difcovered in thefe; though, if there were any fuch, their great tranfparence muft needs make them very eafily diftinguifhable; nor could its dilatations and contractions, if fo confiderable as in that clafs of animals, be lefs fo. See ERUCA.

Malpighi imagined that artery, in the caterpillar clafs, a feries of hearts; in its place, however, there may be feen in thefe animals a true heart. It is eafy to obferve in thefe creatures, about the fourth ring of their body, a fmall flefhy part, which has alternate contractions and dilatations, and is not only difcoverable in the body by means of the creature's tranfparence; but on making a proper fection of them in the fecond, third, and fourth rings, will be thrown out of the body of the creature, and will afterwards continue its beats for fome minutes. *Reaumur*'s Hift. Infect. vol. 4. p. 166, feq.

MAGIC (*Cycl.*)—The moft ignorant and barbarous people have been generally moft fufpected of *Magic*. Among ourfelves, the moft miferably ignorant perfons have been accufed of it; and among foreign nations the Laplanders and Iflanders have been fuppofed moft converfant of all others in it. Thefe people themfelves place an abfolute confidence in the effects of certain idle words and actions, and the reft of the world is deceived in the fame manner. The famous *magical drum* of the Laplanders is ftill in conftant ufe in that nation, and Scheffer, in his hiftory of Lapland, has given us an account of its ftructure.

This inftrument is made of beech, pine, or fir, fplit in the middle, and hollowed on the flat fide where the drum is to be made. The hollow is of an oval figure, and is covered with a fkin clean dreffed, and painted with figures of various kinds, fuch as ftars, funs, and moons, animals, and plants, and even countries, lakes, and rivers; and of later days, fince the preaching chriftianity among them, the acts and fufferings of our Saviour and his apoftles, are often added to the reft. All thefe figures are feparated by lines into three regions or clufters.

There is befide thefe parts of the drum an index and a hammer. The index is a bundle of brafs or iron rings, the biggeft of which has a hole in its middle, and the fmaller ones are hung to it. The hammer or drum-ftick is made of the horn of a rein deer, and with this they beat the drum fo as to make thefe rings move, they being laid on the top for that purpofe. In the motion of thefe rings about the pictures figured

gured on the drum, they fancy to themfelves fome prediction in regard to the things they are to enquire about.

What they principally enquire into by this inftrument, are three things: 1. What facrifices they fhall offer as moft acceptable to their gods. 2. What fuccefs they fhall have in their bufineffes or undertakings, fuch as hunting, fifhing, curing of difeafes, and the like. And, 3. What is done in places remote from them. On thefe feveral occafions they ufe feveral peculiar ceremonies, and place themfelves in feveral odd poftures as they beat the drum, which influences the rings to one or the other fide, and to come nearer to one or the other fet of figures. And when they have done this, they have a method of calculating a difcovery, which they keep as a great fecret, but which feems merely the bufinefs of imagination in the diviner or magician.

MAGICAL (*Cycl.*)—MAGICAL *arrows*, a fort of weapon very common among the barbarous inhabitants of Lapland, and many other of the northern climates, and fuppofed to poffefs great and very ftrange virtues. The people who are poffeffed of them, pretend that they can, by their means, caufe difeafes even to people at a great diftance from them; and not only difeafes, but any other kind of mifchiefs they defire; and they pretend to practife this not only againft ftrangers, but one another. There is a ftory recorded in Scheffer's hiftory of this country, as a legend univerfally believed among them, of a magician who, by means of one of thefe arrows, tore up a rock, near which another magician, with whom he was at enmity, was fleeping, and buried him under it.

MAGIOTAN, a name given by the people of Provence, and fome other places, to the ftony matter, as they efteem it, which choaks up in time the mouths of fome of their rivers. This is a foft fpongy matter, refembling a coarfe and very friable ftone; and, according to the opinion of count Marfigli, it is no other than a congeries of the fand from the bottoms of the rivers farther up the country, which is rolled downwards, and in thefe places is full of fparry and bituminous matter, which, in the place where it meets the full body of fea-water, is ftopp'd and coagulated by it into this firm and folid ftate.

MAGMA, a word ufed by medical writers on many occafions, fometimes in a very lax, and fometimes in a more appropriated fenfe. Some writers ufe it to exprefs a mafs of any thing; others for a thick ointment made up with very little fluid matter, to prevent its running; and others for the remains of an ointment after expreffion from its ingredients. Galen reftrains the word *Magma* to exprefs only the fæces of mirobalans.

MAGNA (*Cycl.*)—MAGNA *Affiza eligenda*, a writ directed to the fheriff to fummon four lawful knights before the juftices, of affize, there, upon their oaths, to chufe twelve knights of the vicinage, &c. to pafs upon the *great affize* between A. B. plaintiff, and C. D. defendant, &c. Reg. Orig. 8. *Cowel.*

MAGNALE, a word ufed by Van Helmont, and other enthufiaftical chemifts, to exprefs what he calls a kind of fpirit, which adminifters to fympathy and antipathy, and is the prompter and promoter of actions, and by virtue of which magnetifm is conveyed, as by a vehicle, to a diftant object. In other places he fays *Magnale*, in mixed fubftances, is the æther, which is thinner than the air; and, as he expreffes it, of an ambiguous nature between body and no body. In other places he fays, that as the *Magnale* has nothing like itfelf in created beings, fo it will admit of no manifeftation by refemblance. The *Magnale*, he fays, is not light, as many fuppofe, but is a fort of conjugal form affifting the air.

MAGNANINE, in zoology, the name of a fmall bird defcribed by Aldrovand, Gefner, and fome other authors, and feeming to be the fame with our hedge-fparrow, commonly known among authors by the name *curruca*. *Ray*'s Ornitholog. p. 158.

MAGNES *Carneus*, in natural hiftory, a name given by Cardan, and fome other authors, to a white earth dug in Italy and fome other places, and called alfo by many *calamita alba*. It is an indurated earthy fubftance of the hardnefs of ofteocolla, and is of a white colour variegated with black lines. It adheres very firmly to the tongue, and is hence faid to attract flefh in the fame manner as the magnet does iron. It is even pretended, that if an iron ftylus be rubed over with this ftony earth, and then plunged into the flefh, the virtue of the earth will heal the wound as foon as made, and when the weapon is taken forth, there will remain no appearance of hurt. Cardan affirms that he faw this tried with fuccefs, but fufpects witchcraft in the cafe! *De Boot.* de Gem. p. 474.

MAGNET (*Cycl.*)—MAGNET, in medicine. Some writers of the middle ages have, from a miftaken tranflation of Theophraftus, been induced to account the *loadftone* poifonous, which the antients were fo far from doing, that they gave it inwardly. Galen afcribes a purgative quality to it, and recommends it in dropfies; and Diofcorides prefcribes it as a good medicine to evacuate grofs melancholic humors.

It is doubtlefs poffeffed of the fame virtues with the other ores of iron, though of late never ufed inwardly, being only made an ingredient in fome plafters.

Arfenical MAGNET, a cauftic made of equal quantities of antimony, common fulphur, and white cryftalline arfenic; which are to be kept in a fand heat, till the whole melts into one uniform mafs. It fucceeds very well in taking down fungous flefh in wounds.

MAGNETIC *Needle*, in navigation, &c. See the article NEEDLE, *Cycl.*

MAGNETICAL *Meridian*, in navigation. See the article MERIDIAN, *Cycl.*

MAGNETIS *Lapis*, in the natural hiftory of the antients, the name given in different ages to two very different fubftances. The earlieft Greek authors expreffed by it the loadftone, which became afterwards called *heraclius lapis*; and then the word *Magnetis* was applied to a very different ftone brought from the fame place, the neighbourhood of Magnefia in Lydia.

This was a fine beautiful and bright fubftance, of a pure white, and fo very bright and gloffy, as to carry a refemblance of polifhed filver. It was dug in large maffes, and was of a texture eafy to be wrought into any figure; this made it in great efteem among the antients, who had it in conftant ufe turned into veffels of different kinds for the ufe of the table. It feems to be wholly unknown at prefent among the nations we have commerce with. *Hill's* Theophraft. p. 79.

MAGNISSA, in mineralogy, a name given by fome of the antients to the white pyrites, called by others *leucolithos* and *argyrolithos*. Many have fuppofed the *Magniffa* to be the fame with the magnefia, that is, manganefe, but this is an error; nor is there the leaft fimilitude between the two ftones. It is plain, indeed, that the antients called a white and filvery looking ftone alfo by the name *Magnefia*; but neither does this appear to have been the *Magniffa* here defcribed, for Theophraftus defcribes it as a ftone that artificers ufed for turning things out of, which is utterly impoffible to be done with the pyrites; the fhattery texture of which would make it fall to pieces on the flighteft attempt to cut it into fhape by the wheel. The chemifts of the preceding ages have plainly underftood this word *Magniffa* of the pyrites, and have made thefe two words and the *fory* fynonymous. Pliny mentions a gold-coloured and filver-coloured pyrites; thefe therefore were diftinctions fufficient for the white and yellow pyrites; but Diofcorides has only mentioned one kind of the marcafite or pyrites, which is the yellow or braffy one, the moft common of all the fpecies. When the word pyrites, therefore, was only the name of this yellow ftone, it is not wonderful that the white one fhould be called by another name, as *Magniffa*. See the article MARCASITE.

MAGNITUDE (*Cycl.*)—*Geometrical magnitudes* may be ufefully confidered as generated or produced by motion. Thus, lines may be conceived as generated by the motion of points; furfaces, by the motion of lines; folids, by the motion of furfaces; angles may be fuppofed to be generated by the rotation of their fides.

Geometrical magnitude is always underftood to confift of parts; and to have no parts, or to have no *Magnitude*, are confidered as equivalent in this fcience. There is, however, no neceffity for confidering *Magnitude* as made up of an infinite number of fmall parts; it is fufficient that no quantity can be fuppofed to be fo fmall, but it may be conceived to be farther diminifhed; and it is obvious, that we are not to eftimate the number of parts that may be conceived in a given *Magnitude*, by thofe which in particular determinate circumftances may be actually perceived in it by fenfe, fince a greater number of parts become fenfible, by varying the circumftances in which it is perceived. See *Mac Laurin*'s Fluxions, Art. 290, 291.

Many of late have fuppofed geometrical *Magnitude* to be compofed of infinitely fmall parts, and infinite in number; and hence have raifed many paradoxes and myfteries in a fcience wherein there ought to be none. Nay, infinitely fmall parts of infinitely fmall parts, &c. *ad infinitum*, have been introduced without the leaft neceffity. See *Mac Laurin*'s Fluxions in the Introduction, where he makes feveral remarks on Monfieur de Fontenelle's *Geometrie de L'infini*. See the article EXTENSION.

MAGNOLIA, in botany, the name of a very beautiful genus of plants, the characters of which are thefe: The perianthium is compofed of three oval and hollow leaves, which look like petals, and fall with the flower. The flower confifts of nine petals of an oblong form, hollowed, narrow at the bafe, and broader at the apex, and terminating in an obtufe point. The ftamina are very numerous, fhort, and pointed filaments; they grow to the common receptacle of the piftil, which is placed beneath the germen, and are of a compreffed figure. The antheræ are oblong and flender, and grow on every fide to the filaments; the germina are numerous, of an oval oblong figure, and are placed about a clavated receptacle; the ftyles are crooked and contorted; the ftigmata are placed longitudinally on the ftyles, and are hairy; the fruit is a ftrobilus of an oval form, with compreffed, roundifh, and fcarce imbricated capfules; thefe are compofed of two valves, and contain one cell; they ftand clofe to one another without pedicles, and open in their outer part. The feeds are fingle, and hang

hang by a thread from every fcale or capfule of the fruit when that is fo ripe as to burft thofe fcales. *Linnæi* Gen. Plan. p. 254. *Dillen.* Hort. Elth. p. 168.

MAGNUM *Os Carpi*. This is the third bone of the fecond row in the carpus, and is the largeft of all the bones of that part. It is of a confiderable length, and has a kind of articular round head, which is received into the cotyloide cavity formed by the two firft bones of the firft row; and this articulation is capable of a fmall degree of flexion and extenfion. The digital fide is a cartilaginous bafis unequally and obliquely triangular, the apex being turned inward. It is articulated with the fecond metacarpal bone, and is alfo a little notched on the radial edge for its articulation with the fmall edge of the metacarpal bone. The radial fide is very fmall, and near the bafis, being articulated with the os pyramidale; the reft of this furface is without cartilage; the cubital fide is double, anfwering to a like fide in the os uniforme with which it is articulated. The outer furface, which forms a part of the outer furface of the carpus, is broad, rough, and uneven, for the infertion of ligaments; the inner furface is likewife rough, but narrower; and round both furfaces are feveral depreffions, which, while the bone is in the body, are filled with fmall glands, ligaments, &c. *Winflow*'s Anatomy, p. 84.

MAGODUS, among the Romans, a name given to thofe players who fometimes acted the part of men, and fometimes of women. *Pitifc.* Lex. Ant. in voc.

MAGOSTANS, in botany, the name by which Garcias calls the genus of plants, afterwards named by Linnæus *garcinia*. See the article GARCINIA.

MAGRA, a word ufed by fome writers for a fort of red earth, and by others for the cornelian, the red jafper, or any other ftone of a red colour.

MAGUDARIS, a name by which Diofcorides calls the filphium. See SILPHIUM.

MAGYDARIS, in botany, a name ufed by Theophraftus, and other of the old authors, for the laferpitium or laferwort. *Ger.* Emac. Ind. 2. See LASERPITIUM.

MAHALEB, in the materia medica, the name of the fruit of a fort of wild cherry called *cerafus fylveftris amara*, or the wild bitter cherry, by Bauhine. The wood of the tree is of a greyifh caft and fine grain, with a mixture of red in the veins, and is very firm, and of a fweet fmell; the leaves and flower carry a rude refemblance of thofe of the common cherry; the fruit is round, black, and refembles a cherry, having the fame fort of ftone in it, the kernel of which is like the bitter almond in tafte. It is commended in external applications, and the perfumers of France ufe it in their wafhballs. It is to be chofen frefh and fweet, for it very often has an intolerable ftinking fmell, like that of bugs. *Lemery*'s Dict. of Drugs.

MAHOMET *Pigeon*, the common Englifh name of a fpecies of pigeon, called by Moore the *columba numidica alba*. It is of the fame fhape and fize with the Barbary pigeon, and has all the characters of that fpecies, but is always perfectly white, which gives the red circle about the eyes a more lively look. *Moore's* Columbarium, p. 51.

MAJA, in zoology, the name of a bird defcribed by Nieremberg as very common in the ifland of Cuba, and frequenting the fields of rice in large flocks. It is defcribed to be a fmall bird of a yellowifh colour, very delicate, and well tafted, and remarkable for having a ftomach on the back or outfide of the neck. *Ray*'s Ornithol. p. 297.

MAIAGUE, in zoology, the name of a Brafilian bird of the web-footed kind, but having its hinder toe loofe. It is of the fize of the common goofe; its head is large and round; its neck long, and it always carries it crooked like the fwan; its beak is ftrong and hooked at the end; it is all over of a brownifh black in colour, except that its throat is yellow. It is found about the mouths of rivers, and feeds on fifh; it builds on the ground; it is very nimble both in running, flying, and diving, and is not eafily taken, but is a very well-tafted fowl. *Marggrave*'s Hift. Brafil.

MAIDEN (*Cycl.*)—MAIDEN *Affizes*, affizes where no perfon is condemned to die, are thus called.

MAIDEN-*hair*, *Adiantum*, in medicine. See the article ADIANTUM.

MAIDEN-*rents*, in our old writers, a noble paid by the tenants of fome manors on their marriage. This was faid to be given to the lord, for his omitting the cuftom of marcheta, whereby he was to have the firft night's lodging with his tenant's wife, but it feems more probably to have been a fine for a licence to marry a daughter. *Blount.*

MAILE, in our old writers, a fmall kind of money. Silver half-pence were likewife termed *Mailes*, 9 Hen. 5. By indenture in the mint, a pound weight of old fterling filver was to be coined into three hundred and fixty fterlings, or pennies, or feven hundred and twenty *Mailes*, or half-pennies, or one thoufand four hundred and forty farthings. *Lownd*'s Eff. on Coins, p. 38. *Blount.*

MAIN, (*Cycl.*) a term applied to feveral parts of a fhip, as the *Main-capftan*, *Main-maft*, *Main-top-maft*, *Main-fail*, &c. and fignifying the chief or largeft of the kind. See the articles CAPSTAN, MAST, SAIL, &c.

MAIN-*body of an army*, is the body of troops that marches between the advance and the rear guard. In a camp it is that part of an army which is encamped betwixt the right and left wing.

MAINIS, in ichthyology, a name ufed by Ariftotle, Athæneus, and others of the old Greek writers, for the fifh now called the *mena menerela*, and *menola*. It is a fpecies of the fparus, and is diftinguifhed from all the other fpecies of that genus, by having four large teeth, and a variegated body, ornamented with a black fpot in the middle of the fides. This is the fifh the Narbons call *jafcele*. See the article SPARUS.

MAINPERNABLE, in law, is applied to one that is bailable, or who may be let to bail. *Terms of law*, *Blount*. See the article BAIL, *Cycl.*

MAINTAINERS, are thofe that maintain or fecond a caufe depending between others, by difburfing money, or making friends for either party, &c. not being interefted in the fuit; or attornies employed therein. Stat. 19 Hen. 7. c. 14. *Blount.* See the article MAINTENANCE, *Cycl.*

MAJOR (*Cycl.*)—MAJOR *Helicis*, in anatomy, a name given by Albinus to one of the mufcles of the eye, called by Santorini and others, *helicis mufculus*. This author diftinguifhes it under the name *Major*, from another mufcle which he calls the *minor helicis*, and which Santorini calls only *fibræ mufculares in plana helicis facie*, tho' it be a true and proper mufcle.

MAJORANA, *Marjoram*, in botany, the name of a genus of plants, the characters of which are thefe: The flowers and feeds are wholly like thofe of origanum, but the heads are rounder, more denfe, compact, and fhort, and compofed of four orders of leaves, placed regularly in the manner of fcales. *Tourn.* Inft. p. 199.

The fpecies of *Marjoram*, enumerated by Mr. Tournefort, are thefe: 1. The common fweet *Marjoram*. 2. The broad-leaved golden *Marjoram*. 3. The round-leaved hairy *Marjoram*, with the fmell of favory. 4. The round-leaved fentellated *Marjoram*. And 5. The narrow-leaved woody *Marjoram*.

Marjoram is an attenuant, diffolvent, and detergent. It is good in nervous cafes, and diforders of the breaft and lungs. Its flowery tops, dried and powdered, and given a fcruple for a dofe, are greatly recommended in epileptic cafes. The dried plant is only kept in the fhops.

The common fweet *Marjoram*, though a plant fo commonly cultivated with us, never ripens its feeds in England: And, as it is an annual plant, we are obliged yearly to have a fupply of its feeds from Marfeilles, and other places in the fouth of France, where it grows wild in great abundance.

It is to be fown in the latter end of March, or beginning of April, on a dry warm fpot; and when they are come up, they muft be carefully watered and cleared from weeds. In June the plants will be grown pretty ftrong, at which time fome beds of rich light earth fhould be prepared, to tranfplant fuch into as ftand too thick. Thefe muft be planted at four inches diftance, and the others left in the fame manner. Thefe are to be watered till they have taken root; and it is always found that thofe which have been tranfplanted produce finer and larger knots of heads, than thofe which remain where they were fown. They flower toward the latter end of July, at which time they are to be pulled up, and dried in a fhady place for ufe. *Miller*'s Gardener's Dict.

MAIZ. The Indians in New England, and many of our other fettlements in America, had no other vegetable but *Maiz*, or Indian corn, for the making their bread of. They call it *weachin*; and where our colonies are at this time numerous, there is yet much of the bread of the country made of this grain, not of the European corn.

The ear of the *Maiz* yields a much greater quantity of grain than any of our corn ears. There are commonly about eight rows of grains in the ear, often more if the ground be good. Each of thefe rows contains at leaft thirty grains, and each of thefe gives much more flour than a grain of any of our corn. The grains are ufually either white or yellowifh, but fometimes they are red, bluifh, greenifh, or olive-colour'd, and fometimes ftriped and variegated.

This fort of grain, though fo effentially neceffary to the natives of the place, is yet liable to many accidents. It does not ripen till the end of September; fo that the rains often fall heavy upon it while on the ftalk, and the birds, in general, peck it, while it is foft and unripe. Nature has, to defend it from thefe accidents, covered it with a thick hufk, which keeps off flight rains very well; but the birds, if not frighted away, often eat thro' it, and devour great quantity of the grain.

There feem to be three or four diftinct fpecies of *Maiz*, in different parts of America. That of Virginia is very tall and robuft, growing to feven or eight foot high; that of New England is fhorter and lower. And the Indians, further up in the country, have a yet fmaller kind in common ufe. The ftalk of the *Maiz* is jointed like the fugar cane; it is very foft and juicy, and the juice is fo fweet and faccharine, that a fyrup, as fweet as that of fugar, has been often made of it; and things fweetened with it have been found not diftinguifhable from thofe done with fugar. It has not been tried yet whether it will cryftallize into fugar; but in all probability it will.

The Americans plant this corn any time from the beginning of March to the beginning of June; but the beft feafon is the middle of April. The favage Indians, who knew nothing of our account of months, ufed to guide themfelves in the feed-time of this ufeful plant, by the budding of fome particular trees of that country, and by the coming up of a fort of fifh into their rivers, which they call the *aloofe*. Thefe things were both fo regular, that they were in no danger of miftaking the time. Phil. Tranf. N°. 142.

The manner of planting *Maiz* is in rows, at equal diftances, every way about five or fix feet. They open the earth with a hoe, taking away the furface to five or fix inches deep, and of the breadth of the hoe; they then throw in a little of the finer earth, fo as to leave the hole four inches deep, or thereabouts, and in each of thefe holes they place four or five grains at a little diftance from one another. If two or three of thefe grow up, it is very well; fome of them are ufually deftroyed either by the birds or other animals.

When the young plants appear, they hoe up the weeds from time to time; and when the ftalk gathers fome ftrength, they raife the earth a little about it, and continue this at every hoeing, till it begins to put forth the ears; then they enlarge the hill of earth, round the root, to the fize of a hop-hill, and after this they leave it till the time of harveft without any farther care.

When they gather the ears, they either immediately ftrip off the corn, or elfe hang up the ears, tied in traces at diftances from one another; for if they are laid near together, they will heat and rot, or elfe fprout and grow; but kept cool and feparate, they will remain good all the winter. The beft method of all others, is to threfh out the corn as foon as the harveft is over, and then lay it up in holes of the ground, well lined with mats, grafs, or the like, and afterwards covered at top with more earth. The moft careful among the Indians ufe this method, and this fort of fubterranean granary always proves good. Id. Ibid. See the article TRACING.

The ufes of this plant among the Indians are very many. The great article is the making their bread of it; but befides this, the ftalks, when cut up before they are too much dried, are an excellent winter food for cattle; but they ufually leave them on the ground for the cattle to feed on. The hufks about the ear are ufually feparated from the reft, and make a particular fort of fodder, not inferior to our hay. The Indian women have a way of flitting them into narrow parts, and they then weave them artificially into bafkets and many other toys.

The original way of eating the grain, among the Indians, was this: They boiled it whole in water till it fwelled and became tender, and then they fed on it either alone, or eat it with their fifh and venifon, inftead of bread. After this, they found the way of boiling it into a fort of pudding, after bruifing it in a mortar; but the way of reducing it to flour is the beft of all. They do this by parching it carefully in the fire, without burning, and then beating it in mortars, and fifting it. This flour they lay up in bags, as their conftant provifion, and take it out with them when they go to war, eating it either dry or with water. Id. Ibid.

MAKINBOY, a name given by the people of Ireland to a kind of fpurge, or tithymale, common there: This is a very violent purge, as all the other fpurges are; but the Irifh have an opinion, that it will produce this effect only by being carried in the pocket. This opinion, which had been univerfally believed for many ages, was proved to be falfe by Dr. Mullen, who carried a large quantity of it about him many days together, on purpofe to give a fair trial; but it had not any the leaft effect on him.

MAKING *Up*, a term ufed by the diftillers to exprefs the bringing fpirits to a certain ftandard of ftrength by the addition of water. See LOWERING.

It is ufed principally in the diftilling fpirits, after their firft drawing, either by way of rectifying them, or of giving them the virtues of aromatic ingredients, in order to make the compound waters; fuch as cinnamon, annifeed, and the like. See DISTILLERY.

In the making thefe compounds, fome ufe an alcohol, or totally inflammable fpirit, which is much the beft method; others ufe ordinary proof fpirit of malt, or melaffes. If the latter be ufed, it is beft not to put any water with it into the ftill; but if the former, fo much water is to be added as will reduce it to the proof ftrength, which is juft an equal quantity. When this is done, there fhould be drawn off three fifths of the whole by diftillation; and the far better way would be to keep this liquor in this very ftate, which is juft the ftrength of the trois cinques brandy of the French: But as people require thefe waters to be kept for drinking, in fuch a ftate as not to exceed, at the utmoft, the ftrength of proof fpirit, generally to fall much fhort of it, it is neceffary to reduce this three fifths, to the whole, or more than the whole quantity of the proof fpirit put into the ftill. The apothecaries, to this end, ufually let the ftill continue to work without changing the receiver, till an equal quantity is produced to the fpirit put in, or one fourth more; it being the ufual ftandard in thefe waters, to have five quarts made from a gallon of the fpirit. By the method of doing this, by letting the ftill run, the faints are taken into the water, and give it a vapid and difagreeable tafte. Inftead of this the diftiller, when he has drawn off his three fifths of the quantity of proof, makes up the whole to the deftined quantity, by adding the two other fifths, or more than that, if requir'd, of common water, in which it is alfo cuftomary to diffolve fome fine fugar; and this gives a fullnefs in the mouth to the water, and makes it mellow, or loofe the fiery tafte of the ftill much fooner. If it be only made up to the ftrength of proof, it will mellow much fooner than if reduced one fifth below that ftandard, as the oil is much more perfectly diffolved in fpirit of a ftandard proof ftrength, than in fuch as is weaker.

The water employed in the *making up*, fhould be either foft and clear river water, or elfe fpring water rendered foft by diftillation, otherwife it is apt to turn the water thick, and precipitate a fediment, efpecially if the water be drawn lower than proof, or if the fpirit, originally employed, partake of an alkaline nature from the falts ufed in its rectification, as is ufually the cafe in the malt fpirits, the grofs oil of which requires to be feparated, by mixing falt of tartar or pot-afh with it in the ftill in the rectification.

When it is neceffary to *make up* waters lower than proof, they are generally cloudy; but this may be remedied, and they may be fined down in a day or two with a fmall quantity of alum, or with whites of eggs, or the jelly of ifinglafs beat up to a froth, and mixed in the fame manner as is ufually done in the refining of wines.

The fugar, added to thefe cordial waters, has not only the advantages of mellowing and filling the mouth, but it unites the oil to the fpirit in a manner that it could never be united in without it. *Shaw's* Effay on Diftillery.

MALA *Aurea*, in botany, a name by which fome authors have called the *poma amoris*, or fruit of the lycoperficon. *J. Bauhin.* vol. 3. p. 620.

MALABATHRUM, among the antients, an excellent fweet-fcented ointment. *Hofm.* Lex. in voc.

MALABATHRUM, *Indian Leaf*, in botany. See the article TAMALAPATRI.

MALACCA *Stones*, a name given by many authors to the pedro del porco, or hog bezoar. A ftone found in the gall-bladder of the Indian boars, and fuppofed as a remedy for the plague, and many other difeafes. It is ufually kept in a gold box, and infufed for a few minutes in any liquor, till it communicates a bitternefs to it.

MALACHE, a term ufed by authors in a different fenfe; fometimes expreffing fuch medicines as gently loofen the belly, and fometimes fuch ointments as relax and mollify.

MALACHITES, or MOLOCHITES, in natural hiftory, a fpecies of jafper, but of lefs beauty than moft of thofe of that clafs. It is naturally of a pure and deep green, but fometimes variegated with whitifh or blackifh fpots and clouds. It is found in the Eaft and Weft Indies; alfo in many parts of Europe. See JASPER.

Its amuletic virtues, formerly in great efteem, are too ridiculous to be particularized. It is faid to be a violent purgative, operating both by vomit and ftool, and as fuch given in dropfies, in fo fmall a dofe as five or fix grains. If, as is very probable, its green colour be owing to particles of copper, it is not wonderful that it fhould have this effect; but there are fo many better medicines for this purpofe, as to fuperfede its ufe. See COPPER.

MALACOCISSOS, in botany, a name ufed by fome authors for the common ground ivy, or *hedera terreftris*; and by fome others for the marfh-marygold. *Ger.* Emac. Ind. 2.

MALACODERMATA, in natural hiftory, a term ufed to exprefs fuch animals as have only foft fkins for their covering; in oppofition to the oftracodermata, which have hard fhelly matters for their covering, fuch as crabs, lobfters, &c.

MALACOIDES, in botany, the name of a genus of plants, the characters of which are, that they have the flower of the mallow-kind, but their fruit refembles that of the common bramble, except that it is dry, not juicy. It confifts of a number of capfules, collected into a head, and fixed to a placenta, and containing feeds like thofe of the mallow, or of a kidney-like form.

The fpecies of *Malacoides* are only two. 1. The betony-leav'd kind. 2. The fmall-flowered *Malacoides*, with an angular leaf. *Tourn.* Inft. p. 98.

MALACOPTERYGII, in the Linæan fyftem of zoology, the name of a large order of fifhes which have not prickly fins.

The term is derived from the Greek μαλακος, foft, and πτερυγιον, a fin. The fifh of this order, are thofe which have bony fins, with all their extremities not pointed or fharp, but foft and harmlefs. Of this order are the carp, &c. *Linnæi* Syftema Naturæ, p. 55.

MALACOSTOMOUS, in ichthyography, the name of a large genus of fifhes, called in Englifh the leather-mouth'd kind. Thefe fifhes are wholly deftitute of teeth in their jaws, but have them placed in their throats, near the orifice of the ftomach. *Ray's* Ichthyography, p. 245.

The word is derived from the Greek μαλακὸς, foft, and ςόμα, a mouth. All the fifh of this genus have their fwimming, or air-bladder, divided into two parts; and of this genus are the carp, tench, bream, chub, and the like. *Ray*, Ichthyogr. p. 245.

MALA-

MALACOSTRACA, in natural hiftory, a term ufed by fome, as Ariftotle, to diftinguifh what we call cruftaceous animals of the fea, &c. from thofe which he calls oftracodermata, or teftaceous, as we exprefs it. See table of teftaceous and cruftaceous animals.

Ariftotle fays, that cruftaceous animals, or *Malacoftraca*, are foft within, and hard without; but that though their covering is not apt to be parted by contufions, yet the one part of it may eafily be torn from the other; and the teftaceous animals, or oftracodermata, are foft within, and hard without; and their covering may be bruifed or broken to pieces, though its parts are not liable to be torn from each other. Thefe definitions have been ufually acquiefced in, but being in reallity infufficient for the diftinctions they are intended to make, they have been the origin of great confufion and error. The confequences which Ariftotle puts into his definition or characteriftics, neceffarily arife from doctrines founded on facts; for when the fhell is but one, as is the cafe in all the teftaceous kind, it may be bruifed, or it may be broken, according as it is more or lefs brittle, but it cannot be torn afunder; whereas in the whole cruftaceous kind, the coverings which are over every feveral part, as the legs, back, belly, and tail in lobfters, are joined to each other only by membranes, which though tough may be torn afunder, though the body of the cruft in any part is too firm to be fo torn. The naturalifts of late ages have been much diftreffed about a place for the *echini marini*, or fea urchins, in their cabinets and books, fome calling them teftaceous, and others cruftaceous animals.

It is very evident, however, according to Ariftotle's diftinctions, that the echini are of the clafs of thefe malacoftraca, or cruftaceous animals, for they move upon their fpines, which demonftrates that their covering is moved by parts, and fo put together, that it may be torn afunder, as the legs of a lobfter may from the body; and indeed every fpine is riveted into its proper cruft, which alfo by confequence muft have its peculiar mufcle which guides the motion of the fpine, by means of which the animal moves itfelf about any way that it pleafes; it being peculiar to thefe animals, that they move by rolling about upon their fpines, not by walking upon them, as the other animals do on their legs, the purpofes of which thefe fpines feem formed by nature to anfwer. Phil. Tranf. N° 219. p. 195.

It is evident alfo, even to ocular infpection, that all the crufts of the echini are united by membranes, as they are in the crabs and lobfters. Agoftino Scilla has accurately figured the internal parts of feveral fpecies of thefe animals in his book of petrifactions, and thefe draughts of his put the matter out of all doubt, as they exactly agree with nature, and are of the nature of the joinings of the lobfter kind. The fifh of the echinus kind are by thefe proved to be cruftaceous animals in the ftricteft fenfe of the term.

MALAGMA, a word ufed by fome authors to exprefs a cataplafm in general, of whatever nature, or made of whatever ingredients; but fome have ufed it only for the emollient cataplafms.

Galen never ufes it in any fenfe but the laft; it was a form of medicine meant only for external ufe, and was not very different in its confiftence from a plafter. It feems to have confifted only of emollient ingredients at firft, but afterwards to have been compofed of aftringents, or of medicines of any other kind, whofe virtues could be conveyed under that form; gums, aromatics, falts, and other ftimulating ingredients, often made a part of the compofition; and fometimes a fmall quantity of oil, lard, or wax, entered the mafs; very often the malagma's confifted only of gums diffolved in wine or vinegar, and fometimes only of refins, which naturally hardened of themfelves after being reduced to powder, and mixed with wine and vinegar to a proper confiftence for applying to the part.

MALANKUA, in the materia medica, the name by which fome authors have called the plant whofe root is the round zedoary.

Many indeed efteem the long and round zedoary the roots of different plants, but they feem rather to be only the different parts of the roots of the fame fpecies. Hort. Mal. 11, 17. *Dale*'s Pharmac. p. 251.

MALARMAT, in ichthyology, a name given by authors to the fifh called by fome *lyra atera* and *cornuta*. It is a fpecies of the trigla, and is diftinguifhed by Artedi by the name of the trigla, with many cirri, and with an octogonal body.

MALARUM *Offa*, in anatomy, are the cheek bones; they make the prominent upper part of the cheeks moft remarkable in lean perfons: They form likewife a portion of the orbit, and compleat the zygomatic arches. They have their name from the Latin *mala*, the cheek; they are two in number, and are fituated in the lateral and middle parts of the face. They are, in fome meafure, triangular or irregularly fquare, and are divided into two fides, the external gently convex, the internal unequally concave.

The eminences in each bone are the fuperior or angular orbitary apophyfis, which joins by future with the external angular apophyfis of the os frontis, and affifts in forming the external angle of the orbit: from this apophyfis another fubaltern procefs runs inward on the infide of the bone, one fide of which forms a portion of the orbit, the other a portion of the zygomatic foffa: The inferior or maxillary orbitary apophyfis, which with the angular apophyfis forms the inferior external portion of the orbit: The apophyfis malaris, which is in fome meafure the bafis of the reft, and together with the apophyfis maxillaris, joins the orbitary apophyfis of the os maxillare, and the zygomatic apophyfis, which makes a part of the zygoma, and alfo of the zygomatic foffa.

The cavities are the great orbitary flope, which makes the inferior external portion of the edge of the orbit; the zygomatic notch above the zygoma, and one or more little holes on the outfide, and in the orbitary apophyfis. Each bone is compofed of two pretty compact tables, with a fmall quantity of diploe between them, except in the anterior part of the apophyfis malaris. The os malæ on each fide is joined to the os frontis by the angular apophyfis; to the os fphœnoides by the fubaltern apophyfis; to the os temporis by the zygomatic apophyfis; and to the os maxillare by its bafis. *Winflow*'s Anatomy, p. 34.

MALKARABÆLA, in zoology, the name of an Eaft Indian fpecies of ferpent found in the ifland of Ceylon. It is remarkably variegated with white and dufky-brown, in various figures. *Ray*'s Syn. Anim. p. 332.

MALL, or *Sea*-MALL, in zoology, the Englifh name of a bird of the gull or larus kind, and diftinguifhed by authors by the name of *larus cinereus minor*. It is very like the *larus cinereus major*, or herring gull, but much fmaller, not weighing above a pound. Its head and neck are grey, with fome brown fpots; the lower part of the neck is white, the back is grey, and the breaft and belly white as fnow; the tail is alfo perfectly white, and is not forked. *Ray*'s Ornitholog. p. 263.

MALLEOLUS, in ichthyology, a name given by Gaza and fome others, to the fifh called by Ariftotle and the other old writers, *fphyræna*, and by the Italians *luzzo marino*.

It is a beautiful fifh, and feems to belong to the fcombri, or mackrel kind. Salvian has figured it under the name of *judis*, a name by which it is alfo called by Varro and fome other old authors, but Salvian's figure is very imperfect; he has omitted the back fin.

MALLEOLI, among the Romans, bundles of any combuftible matter befmeared with pitch, and ufed by the Roman foldiers either for giving light in the night-time, or for fetting fire to fome of the enemies works.

The *Malleoli* were fometimes fixed to a dart or javelin, that they might be fure to catch firm hold, and communicate the fire wherever they happened to light. *Pitifc.* in voc.

MALLEUM *Movens*, in anatomy, a name given by Fabricius to one of the mufcles of the ear, called by Cowper the *internus auris*, and by Albinus, who had confidered its proper ufe, *tenfor tympani*. See TENSOR.

MALLEUS (*Cycl.*)—The *malleus*, or hammer of the ear, is a long bone with a large head, a fmall neck, a handle, and two apophyfes, the one in the neck, the other in the handle. The top of the head is confiderably rounded, and from thence it contracts all the way to the neck; both head and neck are in an inclined fituation, and the eminences and cavities in it anfwer to thofe in the body of the incus. The handle is looked on by fome as one of the apophyfes of the *Malleus*, and in that cafe it is the greateft of the three. It forms an angle with the neck and head, near which it is fomething broad and flat, and decreafes gradually toward its extremity. The apophyfis of the handle, termed by others the fmall or fhort apophyfis of the *Malleus*, terminates the angle already mentioned, being extended toward the neck, and lying in a ftrait line with that fide or border of the handle which lies next it. The apophyfis of the neck, called alfo the apophyfis gracilis, is in a natural ftate very long, but fo flender withal, that it is very eafily broken, efpecially when dry, which is the reafon why the true length of it was for a long time unknown. It arifes from the neck, and fometimes appears much longer than it really is, by the addition of a fmall dried tendon fticking to it. When the *Malleus* is in its true fituation, the head and neck are turned upwards and inwards, the handle downwards, parallel to the long leg of the incus, but more forward; the apophyfis of the handle upwards and outward, near the fuperior portion of the edge of the tympanum, near the center of which is the extremity of the handle; and the apophyfis gracilis forward, reaching all the way to the articular fiffure in the os temporis. By the knowledge of this, the *Malleus* of the right ear may be known from that of the left when out of their places. *Winflow*'s Anat. p. 49.

MALLOW, in botany. See the article MALVA.

MALMIGNATTO, in natural hiftory, a name given by the inhabitants of the ifland of Corfica to a fpecies of animal, or large infect, called by fome *tarantula*, and ignorantly fuppofed to be the fame with the tarantula of Apulia. This ifland produces neither wolves, ferpents, nor many other of the mifchievous and deftructive animals which infeft the neighbouring countries, but it produces two fpecies of this venomous infect, called the *Malmignatto*; the one of thefe has a round body, and the other an oblong one, refembling that of our large kind of ant; it has alfo fix legs, not eight, and never makes any web. From all which it appears not to be a fpider,

but

but truly of the ant kind, though a monſtrous ſized one, and very venomous. The round bodied kind, by its bite, occaſions violent pains, a ſenſation of coldneſs, and cramps all over the body; and the long-bodied one is yet more venomous. Its ſting occaſions an immediate lividneſs of the fleſh, with intolerable cramps and convulſions over the whole body; ſometimes the natural evacuations by ſtool and urine are alſo wholly ſtopped by it. The cure in both caſes, is to be attempted by cutting and cauterizing the wound, and dreſſing it with Venice treacle, as alſo by giving the ſame in large doſes diſſolved in wine. *Boccone*, Muſ. de Fiſ.

MALOGRANATUM, the *Pomgranate*, in botany. See the article POMGRANATE.

MALPIGHIA, in botany, the name of a genus of plants deſcribed by Plumier and Linnæus, the characters of which are theſe: The perianthium is ſmall, hollow, and permanent, and is compoſed of one leaf divided into five ſegments, in the ſinus of each of which there is placed a melliferous glandule. The flower is compoſed of five very large petals, which ſtand hollow, and are of a kidney-like ſhape, with long and ſtrait ungues. The ſtamina are ten broad and erect filaments which grow into a ſort of cylinder. The antheræ are ſimple, the germen of the piſtil is roundiſh and ſmall, the ſtyles are three, they are erect, ſhort, and crowned with obtuſe ſtigmata; the fruit is a large globoſe berry, having one cell, in which are contained three oblong, obtuſe, and hard ſtones, each of which contains an oblong and obtuſe kernel. *Plumier*, Rar. Plant. Hiſt. p. 36. *Linnæi* Gen. Plant. p. 194.

MALPOLON, in zoology, the name of a ſpecies of ſerpent found in the iſland of Ceylon, and very beautifully variegated with red marks in the form of ſtars. *Ray*'s Syn. Anim. p. 332.

MALT (*Cycl.*)—Almoſt every malſter has his ſecret in the making *Malt*, but there are ſome neceſſary cautions to be obſerved by all, which will enſure ſucceſs in the work; theſe are, 1. That the barley be newly thraſhed, or at leaſt newly winnowed. 2. That the whole be of one kind, not mixed up of ſeveral ſorts. 3. That it be not over-ſteeped in the ciſtern, or ſo long as to make it ſoft. 4. That it be well drained. 5. That it be carefully looked after in the wet couch, ſo as to ſtop the firſt tendency of the blade to ſhooting. 6. To turn the wet couch inſide outermoſt, if the barley comes, that is, ſhoots more in the middle than on the ſides. 7. To keep it duly turning after it is out of the wet couch. 8. To give it the proper heating in the dry heap. 9. To dry and criſp it thoroughly on the kiln, but without a fierce fire, ſo as to be ſeveral days in drying a kiln of pale *Malt*. *Shaw*'s lectures, p. 187.

Good *Malt* may be made of the grain of the maiz or Indian corn, but then a particular method muſt be taken for the doing it. Our barley *Malt*-makers have tried all their ſkill to make good *Malt* of it in the ordinary way, but to no purpoſe; that is, the whole grain will not this way be malted or rendered tender or floury, as in other *Malt*; for it is found, by experience, that this corn, before it be fully malted, muſt ſprout out both ways, that is both root and blade, to a conſiderable length, that of a finger at leaſt, and if more the better. For this purpoſe it muſt be laid in a heap a convenient time; and in this proceſs, if it be of a ſufficient thickneſs for coming, it will quickly heat and grow mouldy, and the tender ſprouts will be ſo entangled, that the leaſt moving of the heap will break them off; and the farther maturation of the grain into *Malt*, will be hindered by this means; and on the other hand, if it be laid thin, and often ſtirred and opened to prevent too much heating, thoſe ſprouts which have begun to ſhoot ceaſe growing, and conſequently the corn again ceaſes to be promoted to the mellowneſs of *Malt*. Phil. Tranſ. N° 142.

To avoid all theſe difficulties, the following method is to be uſed: Take away the top of the earth in a garden or field, two or three inches, throwing it up half one way, and half the other; then lay the corn for *Malt* all over the ground ſo as to cover it; the earth that was pared off is now to be laid on again, and nothing more is to be done till the field is all over covered with the green ſhoots of the plant. The earth is then to be taken off, and the roots of the grain will be found ſo entangled together, that they will come up in large cakes or parcels; it muſt be gently waſhed in order to take off all the dirt, and then dried on a kiln, or on a clean floor expoſed to the ſun. Every grain of the maiz will be thus tranſmuted into good *Malt*, and the beer brewed with it will be very pleaſant and very wholeſome, and of an agreeable brown colour, but very clear.

It may be worth trying whether the ſame proceſs is not with due care applicable to the malting of turneps, potatoes, carrots, parſneps, and the like. It might poſſibly be of ſervice alſo to attempt this leſs laborious way of making *Malt* of barley and other ſmall grains; the diſadvantages would be the not ſo eaſily ſeparating the dirt from the grain as in that larger kind; and as barley requires the root only, not the ear, to ſhoot in order to the making of *Malt*, it would be ſome difficulty to know the exact time of taking it up; but with all theſe diſadvantages the method is worth a trial.

MALT *Diſtillery*. This is an extenſive article of trade, and by which very large fortunes are made. The art is to convert fermented *Malt* liquors into a clear inflammable ſpirit, which may either be ſold for uſe in the common ſtate of a proof ſtrength, that is, the ſame ſtrength with French brandy; or is rectified into that purer ſpirit uſually ſold under the name of ſpirit of wine; or made into compound cordial waters, by being diſtilled again from herbs and other ingredients. See the articles BREWING and WASH.

To brew with *Malt* in the moſt advantageous manner, it is neceſſary, 1. That the ſubject be well prepared. 2. That the water be ſuitable and duly applied; and, 3. That ſome certain additions be uſed, or alterations made, according to the ſeaſon of the year, and the intention of the operator; and by a proper regulation in theſe reſpects, all the fermentable parts of the ſubject will thus be brought into the tincture, and become fit for fermentation.

The due preparation of the ſubject conſiſts in its being juſtly *malted* and well ground. When the grain is not ſufficiently *malted* it is apt to prove hard, ſo that the water can have but very little power to diſſolve its ſubſtance; and if it be too much *malted*, a part of the fermentable matter is loſt in that operation. The harder and more flinty the *Malt* is, the finer it ought to be ground; and in all caſes, when intended for diſtillation, it is adviſeable to reduce it to a kind of finer or coarſer meal. When the *Malt* is thus ground, it is found by experience, that great part of the time, trouble, and expence of the brewing is ſaved by it, and yet as large a quantity of ſpirit will be produced; for thus the whole ſubſtance of the *Malt* may remain mixed among the tincture, and be fermented and diſtilled among it. This is a particular that very well deſerves the attention of the *Malt* diſtiller, as that trade is at preſent carried on; for the diſpatch of the buſineſs, and the quantity of ſpirit procured, is more attended to, than the purity or perfection of it.

The ſecret of this matter depends upon the thoroughly mixing, or briſkly agitating and throwing the *Meal* about, firſt in cold, and then in hot water; and repeating this agitation after the fermentation is over, when the thick turbid waſh being immediately committed to the ſtill, already hot and dewy with working, there is no danger of burning, unleſs by accident, even without the farther trouble of ſtirring, which in this caſe is found needleſs, though the quantity be ever ſo large, provided that requiſite care and cleanlineſs be uſed: And thus the buſineſs of brewing and fermenting may very commodiouſly be performed together, or reduced to one ſingle operation. *Shaw*'s Eſſay on Diſtillery.

Whatever water is made choice of, it muſt ſtand in a hot ſtate upon the prepared *Malt*, eſpecially if a clear tincture be deſired, but a known and very conſiderable inconvenience attends its being applied too hot, or too near to a ſtate of boiling, or even ſcalding with regard to the hand. To ſave time in this caſe, and to prevent the *Malt* running into lumps and clods, the beſt way is to put a certain meaſured quantity of cold water to the *Malt* firſt; the *Malt* is then to be ſtirred very well with this, ſo as to form a ſort of thin uniform paſte or pudding; after which the remaining quantity of water required may be added in a ſtate of boiling, without the leaſt danger of making what, in the diſtillers language, is called a pudden.

In this manner the due and neceſſary degree of heat in the water, for the extracting all the virtues of the *Malt*, may be hit upon very expeditiouſly, and with a great deal of exactneſs, as the heat of boiling water is a fixed ſtandard which may be let down to any degree by a proportionate mixture of cold water, due allowances being made for the ſeaſon of the year, and for the temperature of the air.

This little obvious improvement, added to the method juſt above hinted for the reducing brewing and fermentation to one operation, will render it practicable to very conſiderable advantage, and the ſpirit improved in quality as well as quantity.

A much more profitable method than that uſually practiſed for the fermenting *Malt* for diſtillation, in order to get its ſpirit, is the following: Take ten pound of *Malt* reduced to a fine meal, and three pounds of common wheat meal: Add to theſe two gallons of cold water, and ſtir them well together, then add five gallons of water boiling hot, and ſtir all together again. Let the whole ſtand two hours, and then ſtir it again, and when grown cold, add to it two ounces of ſolid yeaſt, and ſet it by looſely covered in a warmiſh place to ferment.

This is the Dutch method of preparing what they call the waſh for *Malt* ſpirit, whereby they ſave much trouble and procure a large quantity of ſpirit. Thus commodiouſly reducing the two buſineſſes of brewing and fermenting to one ſingle operation. In England the method is to draw and maſh for ſpirit as they ordinarily do for beer, only inſtead of boiling the wort, they pump it into large coolers, and afterwards run it into their fermenting backs, to be there fermented with yeaſt. Thus they beſtow twice as much labour as is neceſſary, and loſe a large quantity of their ſpirit by leaving the groſs bottoms out of the ſtill for fear of burning. *Shaw*'s Lectures, p. 216.

All simple spirits may be considered in the three different states of low-wines, proof spirit, and alcohol, the intermediate degrees of strength being of less general use; and they are to be judged of only according as they approach to, or recede from these. Low-wines, at a medium, contain a sixth part of pure inflammable spirit, five times as much water as spirit necessarily arising in the operation with a boiling heat. Proof goods contain about one half of the same totally inflammable spirit; and alcohol entirely consists of it.

Malt low-wines, prepared in the common way, are exceeding nauseous; they have, however, a natural vinosity, or pungent agreeable acidity, which would render the spirit agreeable to the palate, were it not for the large quantity of the gross oil of the *Malt* that abounds in it. When this oil is detained in some measure from mixing itself among the low-wines, by the stretching a coarse flannel over the neck of the still, or at the orifice of the worm, the spirit becomes much purer in all respects; it is less fulsome to the taste, less offensive to the smell, and less milky to the eye. *Shaw's* Essay on Distillery.

When these low-wines, in the rectification into proof spirits, are distilled gently, they leave a considerable quantity of this gross fetid oil behind them in the still along with the phlegm; but if the fire be made fierce, this oil is again raised and brought over with the spirit; and being now broken somewhat more fine, it impregnates it in a more nauseous manner than at first. This is the common fault of the *Malt* distiller and of the rectifier both; the latter, instead of separating the spirit from this nasty oil, which is the principal intent of his process, attends only to the leaving the phlegm in such quantity behind, that the spirit may be of a due strength as proof or marketable goods, and brings over the oil in a worse state than before. To this inattention to the proper business of the process, it is owing, that the spirit, after its several rectifications, as they are miscalled, often is found more stinking than when delivered out of the hands of the *Malt* distiller. All this may be prevented by the taking more time in the subsequent distillations, and keeping the fire low and regular, the sudden stirring of the fire, and the hasty way of throwing on fresh fuel, being the general occasions of throwing up the oil by spurts, where the fire in general, during the process, has not been so large as to do that mischief.

The use of a balneum mariæ, instead of the common still, would effectually prevent all this mischief, and give a purer spirit in one rectification, than can otherwise be procured in ten, or indeed according to the common methods at all.

Malt low-wine, when brought to the standard of proof spirit, loses its milky colour, and is perfectly clear and bright, no more oil being contained in it than is perfectly dissolved by the alcohol, and rendered miscible with that proportion of phlegm, which is about one half the liquor; its taste also is cleaner, though not more pleasant; there being less of the thick oil to hang on the tongue in its own form, which is not the case in the low-wines, where the oil being undissolved, adheres to the mouth in its own form, and does not pass lightly over it.

When proof spirit of *Malt* is distilled over again, in order to be rectified into alcohol, or as we usually call it, spirits of wine, if the fire be raised at the time when the faints begin to come off, a very considerable quantity of oil will be raised by it, and will run in the visible form of oil from the nose of the worm. This is not peculiar to *Malt* spirit, but the French brandy shews the same phænomenon, and that in so great a degree, that half an ounce of this oil may be obtained from a single piece of brandy.

Malt spirit, more than any other kind, requires to be brought into the form of alcohol, before it can be used internally, especially as it is now commonly made up in the proof state, with as much of this nauseous and viscous oil as will give it a good crown of bubbles. For this reason it ought to be reduced to an alcohol, or totally inflammable spirit, before it is admitted into any of the medicinal compositions. If it be used without this previous caution, the odious taste of the *Malt* oil will be distinguished among all the other flavours of the ingredients.

Malt spirit, when it has once been reduced to the true form of an alcohol, is afterwards more fit for all the curious internal uses than even French brandy, it being after this purification a more uniform, hungry, tasteless, and impregnable spirit, than any of the other spirits which we esteem so much finer. *Shaw's* Essay on Distillery.

A pure spirit being thus procured, should be kept carefully in vessels of glass or stone, well stopped to prevent the evaporation of any of its volatile part. If preserved in casks, it is apt to impregnate itself very strongly with the wood. The quantity of pure alcohol obtainable from a certain quantity of *Malt*, differs according to the goodness of the subject, the manner of the operation, the season of the year, and the skilfulness of the workman; according to which variations, a quarter of *Malt* will afford from eight or nine, to thirteen or fourteen gallons of alcohol. This should encourage the *Malt* distiller to be careful and diligent in his business, as so very large a part of his profits depends wholly on the well conducting his processes.

After every operation in this business, there remain a quantity of faints, which in their own coarse state ought never to be admitted into the pure spirit; these are to be saved together, and large quantities of them at once wrought into alcohol. It is easy to reduce these to such a state, that they will serve for lamp spirits. Their disagreeable flavour being corrected by the adding of aromatics during the distillations, the reducing them into a perfect and pure alcohol is practicable, but not without such difficulties as render it scarce worth the trader's while. One way of doing it is by distilling them from water into water, and that with a very slow fire. By this means a pure alcohol may be made out of the foulest faints.

The *Malt* distiller always gives his spirit a single rectification *per se*, in order to purify it a little, and make it up proof, but in this state it is not reckoned fit for internal uses, but serves to be distilled into geneva and other ordinary compound strong waters for the vulgar.

The Dutch, who carry on a great trade with *Malt spirit*, never give it any farther rectification than this, and it is therefore that the *Malt spirit* of England is in general so much more in esteem. The Dutch method is only to distil the wash into low-wines, and then to full proof spirit; they then directly make it into Geneva, or else send it as it is to Germany, Guinea, and the East-Indies, for the Dutch have little notion of our rectification. Their spirit is by this means rendered very foul and coarse, and is rendered yet more nauseous by the immoderate use they make of rye meal. *Malt* spirit, in its unrectified state, is usually found to have the common bubble proof, as the *Malt* distiller knows that it will not be marketable without it.

The whole matter requisite to this is, that it have a considerable portion of the gross oil of the *Malt* well broke and mixed along with it; this gives the rectifier a great deal of trouble if he will have the spirit fine; but in the general run of the business, the rectifier does not take out this oil, but breaks it finer, and mixes it faster in by alkaline salts, and disguises its taste by the addition of certain flavouring ingredients. The spirit loses in these processes the vinosity it had when it came out of the hands of the *Malt* distiller, and is in all respects worse, except in the disguise of a mixed flavour. *Shaw's* Essay on Distillery.

The alkaline salts used by the rectifier, destroying the natural vinosity of the spirit, it is necessary to add an extraneous acid in order to give it a new one. The acid they generally use is the *spiritus nitri dulcis*; and the common way of using it is the mixing it to the taste with the rectified spirit: this gives our *Malt* spirit, when well rectified, a flavour somewhat like that of French brandy, but this soon flies off; and the better method is to add a proper quantity of Glauber's strong spirit of nitre to the spirit in the still. The liquor in this case comes over impregnated with it, and the acid being more intimately mixed, the flavour is retained. See the article Spiritus *nitri dulcis*.

Malt-*worm*, in the manege. See the article Crepance.

MALTA *Earth*. See the article Melitensis *terra*.

MALTHA, the name of a voracious fish of the shark kind, called the *sorrat*, and the *lamiola* by some authors, a diminutive of *lamia*, signifying a small shark. Its teeth are broad and pointed as those of the shark; the fish has also many rows of these; the nose is short, and its flesh lax and soft. *Willughby's* Hist. Pisc. p. 50.

MALTHOCODE, a term by which the Greek writers express'd the emollient topical remedies prepared with oil. Hippocrates expresly forbids the use of these in old ulcers.

MALVA, *mallow*, the name of a very large genus of plants, the characters of which are these: The flower consists of one leaf, and is very open at the mouth, and divided into several segments; from the bottom of the flower there arises a pyramidal tube, which is usually loaded with stamina; and from the cup there arises a pistil, which is fixed like a nail to the lower part of the flower, and also to the tube. This ripens into a flat orbicular fruit, though sometimes pointed, usually surrounded by the cup, and composed of a number of capsules, so placed round an axis, as that each of its striæ receive their capsule as if in a kind of articulation. The seed contained in these is usually of the shape of a kidney. This genus is also distinguished from the alcea, or vervain *mallow*, by having its leaves less divided and cut in, and from the althæa, by having them less hoary. *Tourn.* Inst. p. 94.

The species of *Mallow* enumerated by Mr. Tournefort, are these: 1. The rose *Mallow*, or, as we call it, the hollyoak, with round leaves and pale-red flowers. 2. The white flowered roundish leaved rose *Mallow*. 3. The deep red flowered round leaved rose *Mallow*. 4. The shining purple flowered round leaved rose *Mallow*. 5. The blackish red flowered round leaved rose *Mallow*. 6. The violet coloured round leaved rose *Mallow*. 7. The single yellow flowered round leaved rose *Mallow*. 8. The double flowered red round leaved rose *Mallow*. 9. The double white flowered round leaved rose *Mallow*. 10. The double flesh-coloured round leaved rose *Mallow*. 11. The double purple-flowered round leaved rose *Mallow*. 12. The double black-flowered round leaved rose *Mallow*. 13. The double yellow-flowered round

round leaved rose *Mallow*. And, 14. The pale yellow-flowered round leaved rose *Mallow*, without stalk. These are the species of what we call hollyoaks, and most of which we have in our gardens. The others are, 15. The Virginian maple-leaved *Mallow*, with smooth leaves. 16. The hairy Virginian maple-leaved *Mallow*. 17. The American *Mallow* of Caspar Bauhine. 18. The hairy shrubby American *Mallow*, with clustered yellow flowers. 19. The curled-leaved *Mallow*. 20. The cut-leaved large flowered *Mallow*. 21. The white-flowered wild *Mallow*, with sinuated leaves. 22. The blue-flowered wild *Mallow*, with sinuated leaves. 23. The purplish flowered wild *Mallow*, with sinuated leaves. 24. The wild *Mallow*, with sinuated leaves, and blue flowers streaked with white. 25. The wild *Mallow*, with sinuated leaves, and a very small purple flower. 26. The large flowered wild *Mallow*, with a deep green leaf, rounded and much sinuated. 27. The erect wild *Mallow*, with glossy leaves and large flowers. 28. The small flowered rounder leaved wild *Mallow*. 29. The round leaved variegated wild *Mallow*. 30. The stellated *Mallow*, with various leaves. 31. The purple bottomed early *Mallow*, called by authors *malva trimestris*. 32. The ivy leaved *Mallow*. 33. The round leaved smooth Spanish *Mallow*, with large red flowers. 34. The round leaved Italian *Mallow*, with a large purple flower. 35. The annual white-flowered *Mallow*, with the flowers standing in rundles. 36. The hairy *Mallow*, with a heart-fashioned leaf. 37. The hairy annual *Mallow*, with angular leaves, resembling those of ivy. 38. The currant-leaved Portugal *Mallow*. 39. The Indian *Mallow*, with the heart-fashioned leaf. 40. The elm-leaved American *Mallow*, with the rostrated seed. 41. The elm-leaved *Mallow*, with the double-beaked seed. 42. The elm-leaved *Mallow*, with the double-beaked seed, and with flowers standing in long clusters. 43. The roundish-leaved Indian *Mallow*. 44. The mulberry-leaved Canada *Mallow* with double-beaked seeds. 45. The elm-leaved American *Mallow*, with flowers clustered together in the alæ of the leaves. 46. The vine-leaved American *Mallow*, with a roundish echinated fruit. 47. The purple-flowered ivy-leaved American *Mallow*. 48. The low American *Mallow*, with the leaf and the whole appearance of ground-ivy, and with bifurcated capsules. 49. The melon-leaved hairy American *Mallow*. *Tournefort*'s Inst. p. 95, 96.

The fresh roots of *Mallow* are used as a diuretic and emollient, and the dried leaves as an ingredient in clysters, and in emolient fomentations and cataplasms. The antients gave the juice of the *Mallow*, in large doses, for inflammations and obstructions of the viscera. A strong decoction of *Mallow* root is apt to be mucilaginous, and to sit ill on the stomach. It is a good common drink in pleurisies, peripneumonies, and peculiarly in cases of gravel, or inflammations of the kidneys; also in stranguries and suppressions of urine of all kinds.

MALVA *Marina*, the *Sea Mallow*, in botany, a name not very judiciously given by some writers to a species of submarine plant, supposed in some degree to resemble the leaves of the common *Mallow*. It is very common in the places where they fish for coral, and grows to the rocks without any regular root; it is found at different depths, but most usually far from the surface, and its height is usually about two inches. It is of a dusky greenish colour, with an admixture of a faint yellow; it is composed of several leaves of about half an inch broad, and a little more than that in length. Each of these is fastened to a pedicle of about an inch and half long; the leaves are of a fine thin membranaceous substance, but their stalks or pedicles are thick and tough like horn. When examined by the microscope many glandules discover themselves upon the surfaces of the leaves, but the stalks or pedicles are entirely covered with glandules in form of small protuberances, which make it as rough in those parts as the common chagrin. The stalks when cut transversely shew an infinite number of pipes or vessels running up to every part of the leaves. Count Marsigli has given an elegant figure of this, both as it appears to the naked eye, and by the microscope. *Marsigli*, Hist. de la Mer.

MALUS, the *apple tree*, in botany, the name of a genus of trees, the characters of which are these: The flowers are of the rosaceous kind, each being composed of several petals arranged in a circular form; the cup finally becomes a fleshy fruit of a roundish figure, umbilicated and divided within into several cells, containing oblong callous seeds. See the article APPLE.

MALUS *Assyria*, in botany, one of the many names given by the antients to the citron: They also called it *malus medica*, and by several other names, as these were expressive of the country whence they had the fruit. See the articles CITRON and CITREÆ *mensæ*.

MAMIRA, in the materia medica of the Arabians, a root frequently mentioned by Avisenna, Serapion, and other of the Arabian writers. It seems mentioned as a poisonous drug, and is so described, that it seems to be the same with one species of the durunegi, or doronicum of the same authors, and the common doronicum of the shops, distinguished from the antithora, or other sort of durunegi, by the yellowness of the inside of the root. Avisenna says that it is hard and woody, and formed of knots or joints. This is the very description the same author gives of the durunegi of the first or poisonous kind. Paulus Ægineta says its root is composed of several joints also; and Alphagus calls it a *nodose* or jointed root. Some have supposed that the *Mamira* was the same plant which we call small celandine, but this has no title to be placed among the plants suspected as poisonous, nor any other plea to be guessed at as the *Mamira*, but only its roots consisting of many tubercles. Many things beside have been conjectured to be the *Mamira* of the Greeks and Arabians, but the doronicum seems to be the plant.

MAMMEA, in botany, the name of a genus of plants called *mammei* by Plumier. The characters are these: The perianthium is composed of two small deciduous and oval leaves; the flower consists of four roundish concave expanded petals larger than the cup; the stamina are numerous simple filaments, of about half the length of the flower; the antheræ are roundish; the germen of the pistil is roundish; the style is conic, and of the length of the stamina; the stigma is simple and permanent; the fruit is a very large and fleshy berry, of a spherical figure, but acuminated with the style; the seeds are of an oval figure and callous texture, and there are sometimes found four of them, sometimes only one in the single cell of the fruit. *Linnæi* Gen. Plant. p. 234. *Plumier* Gen. p. 4.

MAMMOTH's *Teeth*, or MAMMOUT *Bones*, in natural history, a name given by travellers and other writers to certain fossile teeth, and other bones, found in Russia and some other parts of the world, and that usually at great depths in the earth. The Russians and other people give them this name, supposing them to have belonged to an animal which they describe as being of a monstrous size, and living in caverns under ground. But the true account of them is, that they are in reality the teeth and other bones of elephants, there being no such beast as these people describe.

Breynius has given a very good account of these bones to the Royal Society, which is printed in the Philos. Transactions. He observes, that they are principally found in the northern parts of Siberia about the borders of rivers, toward the icy sea; they are originally buried in the mountains; but when the frosts have cracked the higher banks of those rivers, as they run under the sides of the mountains, the earth falls in, and they are discovered among it. Sometimes compleat skeletons are found in these places, but more frequently the bones of some particular parts of the body, and nothing so frequently as the teeth. The teeth and bones are not always found of the same size, but often small, and appearing to have belonged to young animals, often so large, that the grinders weigh from twenty to forty pounds; and often the ivory tusks or dentes exerti weigh more than two hundred pounds each. It is very evident that these last are the tusks of elephants, and the rest of the bones, when strictly examined, will all be found to have the same origin, all being reducible to some part of the skeleton of that creature. The tusks are actually used as ivory, and the Czar of Muscovy carries on a very large trade with them; they are wrought both there and abroad into combs and other works; and, according to the observation of captain Muller, perfectly resemble the common ivory, except that they are more brittle, and are apt to turn yellow sooner in the using. See Philos. Trans. N° 446. p. 129.

The comparison of the descriptions and figures of the Siberian *Mammoth*'s teeth with the fossile elephant's teeth of Ireland, and some parts of England, proves very clearly that the bodies are the same.

The fossile bones of elephants are found in many other places beside Siberia, but not in such plenty as in this country; Italy, Germany, Poland, England, France, and Ireland, all afford them; but they are more altered by lying in the earth in these places. The greater warmth of these climates may be naturally enough supposed to have brought on this change in them, and the severe cold of Siberia to have been the principal agent in the preserving them intire in the manner in which we see them.

The bones and teeth of elephants found under ground in other places, and called *ebur fossile*, are of the same origin with these, as are also those dignified in the German shops with the pompous title of *unicornu fossile*, the difference in the preservation being all that distinguishes them. Phil. Trans. N° 447. p. 149. and Mem. Acad. Par. 1727.

MAN, in the materia medica of the antients, a name by which manna has been called by the oldest writers. There has been, however, some confusion in the history of manna, owing to the too general use of this word, the same authors using it as the name of several other substances of very different kinds, which came to their hands in form of small granules or flakes like the manna. The fragments of frankincense in particular were called by this name, with the addition of the word *thuris*, and sometimes without, *Man* or *Men* standing singly for that drug.

MAN *the Capstan*, on board a ship. See the article CAPSTAN, *Cycl.* and *Suppl.*

MAN *the Side, or Ladder*, on board a ship, is when an officer, or any person of distinction is at the ship's side ready to come aboard, the men are commanded to wait, and help him up the side.

MAN *the Top, or Yard*, on board a ship, a word of command for the men to go up to the top, or yard, for some particular service.

MAN *of War*, the same with a ship of war. See the articles SHIP and RATE, *Cycl.*

MAN-*Eaters*. See the article ANTHROPOPHAGI.

MAN-*Bird*. See the article BIRD.

MANAA, in the Jewish customs, a kind of offerings made in the temple, otherwise called *Mincha*. The word *Manaa* is used in the septuagint. See the article *Mincha*.

MANANAOG, in the materia medica, a name by which some call the fruit known with us by the name of St. Ignatius's bean. *Pluk.* Mantiss. p. 60.

MANATI, the *sea cow*, a marine animal, the head of which is like that of a calf, but somewhat narrower; its eyes are like those of a dog, its skin very thick and tough, and covered with a few greyish brown hairs. Its usual length is about sixteen foot, and it measures seven or eight foot round the body. At the fore part of the body it has two short legs, with very broad feet, armed with claws; on the hinder part of the body it has no legs, but has a broad tail, with which it swims very swiftly. From the navel to the tail the body gradually lessens, but just at the tail it becomes very broad again. *Clusius. Ray*, Syn. Quad. p. 193.

Its eyes are very small in proportion to its size, and it has, in the place of ears, two apertures like those of the sea calf, and the female has two teats on the breast, for they bring forth two young ones, and nourish them by suck. It feeds on vegetables, usually living in large rivers, and rising near the shore to feed on the herbs and roots that are found there.

MANATI *Lapis*, a name given to a bone, of which there are two found in the head of the *Manati*, or sea cow; they are roundish and are usually of the size of a hand-bell. They are said to have great virtues against the stone and gravel, when burnt to ashes, and given in white wine. The world need not, however, regret the scarcity of this remedy, for probably any animal bone, when burnt to ashes, is possessed of all its virtues.

MANBALLA, in zoology, the Ceylonese name of a species of serpent, called also the *canine*, or *dog-serpent*, from its manner of flying at every thing that comes in its way, as our dogs do. It is of a deep brown colour, beautifully variegated with white. *Ray*, Syn. An. p. 332.

MANBOTE, in our old writers, a compensation or recompense for *homicide*, particularly due to the lord for killing his man or vassal. *Terms of Law*.

MANCANILLA, in botany, a name given by Plumier to a genus of plants, since characterized by Linnæus in the name of Hippomane. See the article HIPPOMANE.

MANCORON, a word used by the antients to express what they call a sort of honey, which seems to have been evidently our modern sugar. They say that it was a sort of dry honey found concreted in canes or reeds, and was of the consistence of salt, and that it was found in India and Arabia Felix, and that when taken into the mouth, it broke under the teeth like salt. See the article SUGAR.

MANDATARY, *Mandatarius*, he to whom a command or charge is given: Also he that comes to a benefice by a *mandamus* is called by this name. *Blount*.

MANDRAGORA, the *Mandrake*, (*Cycl.*) the name of a genus of plants, the characters of which are these: The flower is composed of one leaf, fashioned like a bell, and divided into many segments at the end. This is enclosed in a cup, from the bottom of which rises a pistil, which perforates the base of the flower, and grows finally into a roundish soft fruit, in which are contained a number of seeds, which are usually of the figure of a kidney.

The species of *Mandrake* are, 1. That with a round fruit, called the male *Mandrake*. 2. The bluish or purplish-flower'd kind, called the female. 3. The blue flower'd one, with small leaves, and a round fruit. Most of the *Mandrakes* may be known even when not in flower, by their having large roundish leaves of an ill smell, and very large roots. *Tournefort*, Inst. p. 76.

Mandrake has been recommended in case of barrenness, but without foundation. Its fresh root is a violent purge, the dose being from ten grains to twenty in substance, and from half a dram to a dram in infusion. It has been found to do service in hysteric complaints, but must be used with great caution, otherwise it will bring on convulsions, and many other very mischievous symptoms. It has also a narcotic quality. At present we only use the fresh leaves in anodyne and emollient cataplasms and fomentations.

MANDRAGORITES *Vinum*, *Mandrake Wine*, a sort of medicinal impregnation of wine with the virtues of *Mandrake* root. It is prepared by cutting into thin slices half a pound of the bark of *Mandrake* roots, and stringing them on a thread, and letting them down into a vessel containing nine galllons of white wine, so that they may hang loosely in it, and by that means fully impregnate it with their virtues. It was used in small doses as an anodyne and soporific. It had the same effects also, if only smelled to, and was sometimes injected in clysters to the same purpose. They say that half a pint of this liquor mixed with twelve times its quantity of wine, brings on a carus; and that even a smaller dose than this, less diluted, is mortal.

MANDRAKE, *Mandragora*, in botany and medicine. See the article MANDRAGORA.

MANE-*Sheet*, in the manege, is a sort of covering for the upper part of a horse's head, and all round his neck, which at one end has two holes for the ears to pass through, and then joins to the halter upon the fore part of the head, and likewise to the surcingle, or long girth, upon the horse's back.

MANEGE. A horse is said to *manege* when he works upon volts and airs, which supposes him broke and bred. See the article MANEGE, *Cycl.*

MANEGE *for a Soldier's Horse*, is a gallop of unequal swiftness, but so that the horse changes hands readily.

High MANEGE, is the high or raised airs, which are proper for leaping horses. See the article AIRS, *Cycl.*

MANEGED. A horse is said to be thoroughly *maneged*, or a finished horse, that is well broken, bred, and confirmed in a particular air or manege, so as to bear well upon the hand, know the heels, and sit well upon the hips.

MANGANESE, *Magnesia*, in natural history, a very poor kind of iron ore. See the article IRON.

It is a dense, ponderous, and heavy substance, in its finest and purest pieces, approaching greatly to the texture of the *lapis hæmatites*, being composed of regular parallel stria, diverging from a center to the circumference. This kind, however, is rare; beside which there is another somewhat less pure kind of an iron grey colour, and irregularly streaked like the steel-grained lead ores. But the common *Manganese* is of a perfectly irregular structure. It is very heavy, moderately hard, and of a deep dusky grey, approaching to black, though sometimes of a ferrugineous brown. It is found in large masses of no determinate shape, and of a rude, rugged, and unequal surface.

Manganese gives fire but difficultly with steel, and makes no effervescence with aqua fortis. It is found in many parts of England and Germany.

This substance is of vast use in the glass trade, but neither the industrious Neri, nor any others who have written of the art, can ever deliver the true proportions in which it is to be mixed with the glass metal on the several occasions. The same thing is also to be observed in regard to zaffer, another substance in continual use with them. And the reason of this is, that there is vast difference in the quality of these bodies, some which are sold being very pure and rich, others good for almost nothing, and much of middle degrees of purity between these. For this reason there is no determining how much of each is to be added to the glass, but the conciator adds them at several times and in small quantities, and takes frequent proofs by his eye, till he knows that they are properly proportioned. *Merret's* Notes on Neri, p. 274.

MANGANUM, Μαγγανον, among the Greeks, a general name for instruments to throw large stones with. *Potter*, Arch. Græc. T. 2. p. 95.

MANGARATIA, in botany, a name given by some authors to the plant of which the common ginger of the shops is the root. *Piso*, p. 227.

MANGER, in a ship, a circular place made with planks fastened on the deck, right under the hawses, being about a foot and half in height; the use of which is to catch and receive the sea-water, beating in at the hawses in a stress of weather.

MANGOUSTAN, in natural history, the name of a fruit of the East Indies. The tree which produces it is large, and usually much branched. The leaves are six inches long, and two inches wide, of a lively green, and ornamented with a double series of ribs, one part of which makes a border that surrounds the whole verge of the leaves. The flower is small, and of a pale green colour; it is composed of four petals, which, when they open, shew the rudiments of the fruit forming itself within. These leaves do not fall off at all, but remain fastened to the bottom of the fruit till it is ripe, serving as a sort of support to it. The fruit grows to the bigness of an apple. It is perfectly round, and is covered with a hard and tough skin, which is of the twelfth of an inch thick, and is of a lively red, streaked with several yellow lines, which are so many filaments running along it: At the extremity there are placed several rays, which running to the length of a tenth of an inch, meet together, and terminate in a point. The substance of the fruit is white, soft, and of a very agreeable taste, approaching to that of raspberries. The body of the fruit is composed of several lobes or quarters, as we call them, which will separate from one another like those of an orange; but they are not enclosed each in a separate skin as those are. These are in number the same with the rays at the end of the fruit, that is, there are seven of them. When the fruit is eaten before it is perfectly ripe, the whole is eaten together; but when it is thoroughly ripened, there is found a single kernel in the middle; this is greenish without and white within, and is

is of an insipid taste, and therefore usually thrown away. Mem. Acad. Scienc. Par. 1699.

This is an extremely agreeable fruit, and the eating it is never attended with any bad consequences, even though it be eaten in ever so large quantities. People who are not used to the Indies are apt to give this the preference to all the fruits of the place; but the natives, and others who have accustomed themselves to the smell of the *durion*, give that infinitely the preference. This is a large prickly fruit of the size of a melon, of an intoxicating quality, and of a taste like that of sugar and cream, but with a smell like that of rotten onions. The smell is intolerable to strangers, but custom has made it familiar to the Indians, and they disregard it. The peel or rind of the *Mangoustan* is a more powerful astringent than the pomegranate bark, and is given in decoction in diarrhœas and dysenteries with great success, as also in all other hæmorrhages. There is a sort of wild *Mangoustan*, called by the Portuguese, *mato*, which grows in the woods both in the East Indies and in America. The fruit of this perfectly resembles the true *Mangoustan*, but is not eatable.

MANHEB, a word used by some chemical writers to express scoriæ of any kind.

MANIA, (*Cycl.*) *Madness*, the most violent and acute species of a delirium, arising from a perturbation of the imagination and judgment.

Signs of it. These are a bold and resolute aspect, and eyes suffused with blood; only it is to be observed, as to the first-mentioned symptom, that those persons who have gone *mad* through fear, have always in their aspect a mixture of that terror the object first gave, and of that natural boldness which arises from *Madness*. The patient often lays traps and snares for the getting other people into his power, with intent to hurt them, though they never have in jured him. Sometimes mad people have been known to murther others; and they always have so much strength as to overpower almost any one person; and though they have no actual fever, yet they are insensible of the external cold, and in general of other pains or injuries; nay, they are so lost in speculation, as often scarce to feel the blows and lashes they receive in the course of their cure. They often do not even hear the people who speak to them, and are naturally of a very jocund and chearful imagination, fancying themselves kings and princes, and are delighted with music. They have a violent propensity to venery, and such an absence of shame, that they will go to stool, or do any thing of a like kind, before any body. This is the usual case in the height of the disorder; and in its decline some are dull and stupid, others very sorrowful and melancholy, and sensible of their unhappy disorder. *Junker*, Consp. Med. p. 689.

Persons subject to it. These are principally men of a choleric habit of body, and of violently passionate dispositions. Those who have continual domestic quarrels, are also frequently thrown into *Madness* by it; and women frequently incur this disease from long suppressions of the menses, and a habit of giving loose to lascivious thoughts. Suppressions of the hæmorrhoids, and of the evacuation of the semen, have sometimes also driven men into *Madness*; worms have also sometimes occasioned it, and sometimes drunkenness.

Prognosticks. *Madness* arising from immaterial causes, is much more difficult of cure than when it arises from disorders of the bodily organs; hence when it arises from violent perturbations of the mind, or from intense study, it is almost incurable. When it arises from suppressions of the semen, or of the uterine, or hæmorrhoidal discharges, there is great hope of a cure by proper means. But *mad* persons in general, when they sleep sound, and always awake in outrageous fits, are to be esteemed incurable, or at least greatly more difficult of cure than others.

Method of Cure. A brisk purge is first to be given; after this the patient is to be blooded pretty freely, ten ounces at the least should be taken away; after this the senses are to be attempted to be roused by strong vomits. White hellebore was famous on this occasion among the antients; and there are some cases in which it may be given with safety, and with great good effect. After this the violent emotion of the blood is to be attemperated by nitrous and absorbent medicines; and, after these, the several remedies usually esteemed specifics take place. Of this number are decoctions of the red anagallis or pimpernel, the ruta muraria, or white maidenhair, the several preparations of silver, the berries of the *Herba Paris*, asses blood, and the like; and great care is to be taken to bring the hæmorrhoidal and menstrual discharges as far as possible to regularity. In cases of retention of the semen, purified nitre is to be given in great quantities, and may be also externally used, applying it to the testes in a cataplasm. The use of opiates is scarce to be suffered in any delirium, but of all things is never to be given in *Madness*, for it never gives them any sleep, but enrages and adds to the complaint, having the same effect that strong liquors would have upon them. The use of white hellebore, as a vomit, may be of great service in some cases; but in all hypocondriac complaints, and consequently in *Madness*, in the causes of which these complaints have a share, it is certain to encrease the disease. Id. Ibid. p.691.

We read of a *Mania* arising from a callous pia-mater. See Med. Eff. Edinb. vol. 4. art. 26. See also the article MADNESS.

MANICUM *Strychnum*, in botany, a term used by the old Greek writers to express a kind of nightshade, which, when taken internally, caused madness. Pliny, describing this species, says that it has leaves like the ocymum or basil; and Theophrastus and Dioscorides say it had leaves like the eruca or rocket. Where Pliny had his information is not easy to guess, for he commonly copies from these authors. They are, however, much more to be depended on; and as the leaves of the ocymum or basil are not at all like those of the rocket, Pliny is certainly wrong in his account; and the most probable reason for his error is, that he mistook the Greek name of the plant, to which these authors compared the leaves of the *Manicum Strychnum*, and translated *euzomon*, which is the name of the rocket into ocymum, basil; a name somewhat like the Greek one in sound, but wholly different in signification; the two plants basil and rocket not only having leaves very unlike one another, but being also of different genera. A yet greater error of Pliny, in regard to this plant, is his placing it among the esculent garden herbs, and saying that it was in use as a food, immediately after he had told us of its causing madness in those who eat it. This is an evident confusion of the maniac solanum with the pomum amoris or love-apple, the fruit of which is eaten in soups at this time.

MANIFESTUS *Clitoridis*, in anatomy, a name given by Vesalius and others to one of the muscles of the female pudenda, called by Verheyen simply the *musculus clitoridis*, but by Albinus and Cowper, *erector clitoridis*. Verheyen is not to be censured for calling it only the *musculus clitoridis*, for it is properly the only muscle of that part, the other generally attributed to the clitoris, and called by Riolan and others, *clitoridis inferior* and *latus*, not properly belonging to that part, but being truly a sphincter vaginæ, or as Albinus by a more coarse name calls it, the *constrictor cunni*. See the article SPHINCTER.

MANIHOT, in botany, the name of a genus of plants, the characters of which are these: The flower is of the one-leav'd kind, and is shaped like a bell, and is wide open, and divided into many segments at the edge. The pistil finally becomes a roundish fruit, containing three capsules joined closely together, each of an oblong figure, and containing a seed of the same figure.

The species of *Manihot*, enumerated by Mr. Tournefort, are these: 1. The common *Manihot* of Thevet, called *jucca*, and *cassada*. 2. The prickly American *Manihot*, with vine-like leaves. 3. The American *Manihot*, with broad elm-like leaves. 4. The American *Manihot*, with narrow elm-like leaves. 5. The climbing American *Manihot*, with leaves like betony. And 6. The smallest germander-leav'd American *Manihot*. *Tourn.* Inst. p. 658.

This plant is also called *Manioc*; its juice is poisonous; but the bread made of the plant, after the expression of the juice, is innocent, and in frequent use in the Brasils, and other parts of the West Indies. Mem. Acad. Par. 1700.

MANIQUE, in the materica medica, the name given by authors to an American root, commended greatly for curing tertian and quartan agues, and as an infallible remedy against venomous bites. Redi procured some of this famous root, and gave it many very fair trials, but could never discover any of these virtues in it. *Redi*, Esperien.

MANNA (*Cycl.*)—This is a substance in many things very nearly related to sugar and to honey; it is inflammable in the same manner, and it melts in water as easily as sugar, and in the same manner is indissoluble in spirit of wine, except in regard to a very small quantity of some seemingly extraneous particles: This is a very sufficient proof that salts abound in it more than sulphurs. M. Lemery, in his analysis, drew from *Manna* a vinous liquor, of the same kind with that obtained from honey. Mead may also be made of *Manna*, in the same way that it is made from honey; but it is neither so strong, nor so agreeable to the taste, as that of honey. From as much mead as was made from two pounds of *Manna*, M. Lemery drew off by distillation eight ounces of a sort of brandy, and on rectifying this, procured an ounce and half of a pure burning spirit, like in all respects to rectified spirit of wine. This spirit of *Manna* is accounted by some a sudorific, and is given from half a dram to a dram and a half. M. Lemery having left the remaining liquor, after the distillation of the spirituous part of the *Manna*-mead, in a warm place for two years, found that it deposited to the bottoms of the bottles seven drams of an essential salt of *Manna*, which was white, hard, brittle, and formed into fine needles, and was of an acid taste, with an admixture of sweet. This salt is purgative, and its dose is a dram. All the remaining acid liquor being distilled, there remained at the bottom of the retort a quantity of matter of the consistence of honey, which weigh'd twenty ounces; so that out of two pounds of *Manna*, there had been twelve ounces consumed, to make the spirit, and to give the acidity to the remaining liquor. This honey-like residuum, being finally distilled with a strong fire, there arose a reddish liquor of an acrid taste, and with a strong empyreumatic smell, and with this a few drops of a blackish oil; after this operation, the remainder in the retort was four ounces of a very light black coal. The coal, it is to be observed, is here only one eighth of

of the weight of the *Manna*, which is fomewhat fingular, fince in the pureft honey, treated in the fame manner, it always weighs one fourth of the original whole quantity. It is plain from hence, that *Manna* is a much purer fubftance than honey: It is alfo remarkable, that in farther treatment of this coal, there is a fmall quantity of iron always difcovered in it. *Manna*, honey, and all the other fweet fubftances, we fee, alfo lofe all their fweetnefs, as foon as ever their acid is feparated from their oil. Hift. Acad. Par. 1708. p. 56.

Manna is far from being peculiar to the afh tree of Calabria, on which it is ufually found. It is no other than the matter of the fenfible tranfpiration of trees and plants in general, and is found on many different kinds in different quantities. The lime and fycamore ufually have a great deal of it on their leaves in the heats of fummer, and if fteeped in water, render it fweet and purgative. The fweet matter found in the bottom of the trefoil, or jafmine flowers, is alfo *Manna* in a certain ftate. The bees are well acquainted with the famenefs of this extravafated juice in different plants, and collect it for their honey, as well from the leaves of the lime and fycamore, and many other trees, as from the flowers of plants. The elaboration it fuffers under their management afterward is all that makes the difference between that and what men collect in Calabria; and honey is *Manna* in a certain ftate.

At Briançon in France they collect *Manna* from all forts of trees that grow there; and the inhabitants obferve, that fuch fummers as produce them the greateft quantities of *Manna*, are very fatal to their trees. Their walnut-trees produce annually a confiderable quantity; but if there happen a year in which they produce more than ordinary, they ufually find many of them perifh in the following winter.

It feems very plain from the whole, that *Manna* is only the extravafated juice of the tree, which cannot furvive fo great a lofs of it: And what not a little confirms this is, that the very hot fummers are always thofe which are the moft abundantly productive of *Manna*. The antients were fenfible of this fpontaneous production of *Manna*, of feveral fpecies of trees, fo very different from one another, and from thence fell into the error of fuppofing it fomething wholly foreign to the tree; an error very natural to thofe who did not know that the nutritive juices of very many trees are nearly, if not wholly, the fame. It was from this opinion of its origin, that they called it aerial honey.

My Boyle tells us, that in Apulia and Calabria, between the months of March and November, they obtain, by incifion, from the common afh-tree, a fweet juice fo like *Manna*, in that feafon adhering to the leaves of the fame kind of trees, that they call it *Manna del Corpo*, trunk-*Manna*; and ufe it fuccefsfully. Works abr. vol. 1. p. 51.

MANNA *Alhagina*, a word ufed by fome authors to exprefs that kind of *Manna* called by others *Manna maftichina*, from its drops refembling maftic in fmall tears. It is called *alhagina* from the plant which produces it, it being collected from the *alhagi maurorum*, in the fame manner as the common *Manna* from the Calabrian afh. See the article MANNA *Perficum*, infra.

MANNA *Libanotis*, in the materia medica, a name given by the old Greek writers to the fmall flakes and fragments of the frankinfenfe which flew off the larger pieces in the gathering and putting them up. See the article LEPTOS *Libanotis*.

MANNA *Maftichina*, in the materia medica, a name given by fome authors to a kind of *Manna* which they defcribe as refembling maftic in its colour, and the fize of the lumps it is collected in. This is what we ufually know at this time under the name of *Manna Perficum*, or Perfian *Manna*, which is at this time in ufe in medicine in the Eaft, as a common purge. See the next Section.

MANNA *Perficum*, *Perfian Manna*. It does not appear in the writings of the antient Greek phyficians, that they were acquainted with any fpecies of *Manna*, though that medicine be now fo common in the fhops. They had the word indeed, but they applied it to a very different fenfe; what they called *Manna* being what fome authors ftill call the *Manna* of frankincenfe, that is, fuch pieces of the common olibanum as broke off in the carriage from the larger pieces. Philof. Tranf. N°. 472. p. 86.

The Arabians are by fome fuppofed to have firft brought what we call *Manna* into ufe in medicine; but if they were not the abfolute inventors of this ufe of it, it is certain they were the firft who made it general and common as a purge. Their country afforded feveral diftinct fpecies of *Manna*, all which feem to have been fo common among them, that they thought defcriptions of them needlefs; and for that reafon have not left us fufficient accounts of them, from which to determine what were their characters and differences. They diftinguifhed three kinds of this purging medicine, under three abfolutely different names, which were *Manna*, *tereniabin*, and *firacoft*; but it is not eafily proved whether thefe are all now known, or by what appellations they are at this time diftinguifhed.

Rawwolf, in his itinerary publifhed by Mr. Ray, and Tournefort in his voyage to the Levant, have given the cleareft intimations, in regard to this fubject, of any of the known writers; and if to thefe we add Clufius, we have among the three all that is to be expected of any certainty upon the fubject; yet the defcriptions of thefe, though eye-witneffes of all they write, have not prevented fo eminent and late a writer as Geoffroy from falling into an error concerning the *Manna* of the Arabians. It is very evident, however, that we have ftill one fpecies of the *Manna Arabum*, that is, the *tereniabin*, produced in fome parts of the world, there having been fpecimens of it fent over into England from Peterfburgh, near which place it is collected from a plant, known among botanical writers under the name of *alhagi maurorum*.

This is ufually called *Manna Perficum*; it appears at firft fight a mixed mafs of a dirty reddifh brown colour, but, upon a nearer view, it is feen to confift of feveral forts of particles. Firft, a great number of globular cryftalline and almoft tranfparent bodies of different fizes, and of a yellowifh white colour. The largeft of thefe do not much exceed a large coriander-feed in fize, and they have fomewhat of the appearance of fmall lumps of maftic, but are of a fomewhat reddifh caft. Secondly, there are among thefe a large quantity of fmall prickles, and other little woody bodies, which feem to have been the pedicles of leaves. Thirdly, there are a few fmall leaves, which are of a firm texture, and terminate in narrow points. Fourthly, there are a large number of fmall long reddifh-colour'd pods, of a fweetifh gelatinous tafte, containing from one to fix or feven hard irregular and kidney-fhap'd feeds, which to the tafte are very acerb. And fifthly, there is ufually fome fand and earth among it. Four ounces of this *Manna* diffolved in water ufually leaves about one ounce of thefe fubftances in the filtre.

The globules firft defcribed are fomewhat hard, they break between the teeth like fugar-candy, and are of a pleafant fweet tafte, but have much lefs of the *Manna* flavour than the Calabrian, but enough of it to difcover to what family the fubftance belongs. The feeds, fticks, leaves, and pods, feem to be all of them parts of the plant which produces the *Manna*; and the feeds having been fown with us, have raifed plants of the alhagi. About the year 1537, when Rawwolf wrote his itinerary, it appears that large quantities of this kind of *Manna* were brought from Perfia to Aleppo, where it was then known by the name of *trunfchibil*, or *trunfchibin*, a corruption doubtlefs of the word *terenjabin*, or, as it ought to be written, according to Denfingius, *tereng jabin*.

Rawwolf alfo exprefsly informs us, that this fpecies of *Manna* was gathered from a plant called *alhagi*. This plant is minutely defcribed by Tournefort, who confirms the account of the *Manna* being gathered from it, which Rawwolf had given fo long before.

Tournefort fays, that it is chiefly gathered about Tauris a city of Perfia, under the name of *trunjibin*, or *terenjabin*, mentioned by Avifenna and Serapion; he adds, that thofe authors thought it fell upon certain prickly fhrubs, whereas it is really the nutritious juice of the plant; and that, during the great heats in that part of the world, there are perceived fmall round drops, as it were, of honey ftanding upon the leaves of this plant; and that thefe harden into globules about the fize of coriander-feeds, and are then gathered by the inhabitants, together with leaves, ftalks, dirt, and the like foreign matter, which greatly take off from their virtue. Mr. Tournefort obferves, that this *Manna* is greatly inferior to the Calabrian in virtue; and that twenty or thirty drams of it are given for a dofe. Philof. Tranf. N°. 472. p. 90.

Clufius tells us, that the *terenjabin* of the Arabians is gathered from a prickly fhrub, fuch as the alhagi is defcribed to be; and Avifenna declares, that it was found upon a thorny plant; though his tranflators have been mifled from the near refemblance of two Arabic words, to make it ftones, not a plant, that it was gathered from.

It appears very plainly from the whole, that this fubftance now known in Ruffia, and fome other parts of the world, under the name of *Manna Perficum*, is truly the *terenjabin* of the Arabians and of Clufius, Rawwolf, and Tournefort; only that the word is differently fpelt by the latter authors, and it is probably alfo that *Manna* called by Bauhine, and fome other writers, *Manna Maftichina Orientalis*, from the round globules it is compofed of, refembling the drops of maftic. See the article TERENJABIN.

MANNA *Thuris*, the *Manna of Frankincenfe*, a term ufed by the antient phyficians to exprefs fuch fmall pieces of frankincenfe, or olibanum, as broke off from the larger in the carriage. See the articles MANNA *Perficum*, fupra, and LEPTOS *Libanotis*.

MANNIFERA *Arbor*, in the materia medica, the name by which the round-leav'd afh, on which the manna is found, is often called. *Dale*, Pharm. p. 332.

MANNING, in the navy. To *man* a fhip or fleet, is to provide them with a fufficient number of men for an expedition.

In *manning* the navy, it is ufual to promife, by proclamation, a bounty to all feamen and able-bodied land-men, who come into the fervice by a certain time, which is commonly two months pay, and but feldom any more. This does indeed prevail on a good many, yet great numbers conceal themfelves till the fleet is at fea, and others lurk about till the time limited for fuch bounty is expired, which does not a little prevent the fleet's being in a readinefs for an early expedition.

And

And as seamen are thus encouraged to enter themselves voluntarily, so there is another method used to compel them to it, and that is *pressing*, by warrants from the lord high admiral to the captains, which are by them assigned to their lieutenants: And to render this the more effectual, vessels are purposely hired into the service, to proceed from place to place, with those officers and their press-gangs, not only to receive volunteers, but also to impress what men they can light on. But their success has been very uncertain, and always very expensive; therefore it were much to be wished, in a matter of so great consequence to the nation, that more speedy and effectual methods could be taken for *manning* the fleet.

MANONOETOC, in natural history, a name given by the people of the Philippine Islands to a species of horned owl common in those parts.

MANSORIUS *Musculus*, in anatomy, a name given by some writers to that muscle of the face more generally known under the name of the *Masseter*. See the article MANSORII, *Cycl.*

MANTECU, a sort of preparation of butter used by the Turks when they travel with their caravans. This is first oiled over the fire, and then salted and kept in vessels made of a tough leather, worked round a wooden frame, of the same shape with the vessels in which they bring their balsam from Mecca. *Pocock's* Egypt, p. 186.

MANTICA, in zoology, the name by which Piso and some other writers have expressed the pouch or bag of skin under the belly of the opossum, into which the young are received in time of danger. See the article OPOSSUM.

MANTICHORA, in natural history, a name given by the Roman authors to a fierce and terrible creature, which they describe from the Greeks, who call it sometimes also *Mantichora*; but when they write more correctly *Marticora* and *Martiora*. We have formed the name *man-tiger* on the sound of the Roman name, though expressing a very different sense; and our authors of the histories of animals, figure to us under this name a terrible creature, partly from the accounts of Pliny exaggerated, and partly from their own imagination, with three rows of teeth, and with such a shape as no animal ever possessed. Pliny tells us, that this creature had three rows of teeth which closed in with one another in a surprising manner; and Pausanias, Aristotle, and Ctesias, all agree in the account of its having three rows in the under, and as many in the upper jaw. They also add, that the teeth, when they close, fall in one with another in the manner of the teeth of a comb; and this they have also told us of the crocodile; and that therefore no bite is so terrible as that of these animals. Pliny and Aristotle both add to this, that the *Mantichora* had the face and ears perfectly resembling those of a man; and Aristotle adds, that its eyes were grey or bluish, and perfectly like the eyes of a man also. The voice of this animal is as oddly represented as its body; Ctesias and Aristotle, and many other of the Greek authors, say it had the sound of a musical instrument of the pipe kind; and Pliny says, that it was a sort of mixed sound, like that of the pipe and trumpet together; and Ælian gives it a power of imitating either the one or the other, as it pleased, by the different modulations of its throat. The Greek authors also give it a very great swiftness; but the Latins, not contented with any thing that does not look miraculous in such an animal, give it a power of leaping in its running, which is little less than flying.

The whole story of this animal seems founded on the love of the wonderful; and very probably the *Mantichora*, properly speaking, was no other than some of the large hyænas which was at first ill described, and afterwards more and more wonders were added to the story, till all shadow of truth was lost.

MANTIS, the preying locust. See Tab. of Insects, N°. 4. and the article LOCUST.

MANUAL, *manualis*, signifies what is employed, or used by the hand, and whereof a present profit may be made. Thus such a thing is said to be in the *manual* occupation of one, where it is actually used or employed by him. *Staundf.* Prærog. p. 54. *Cowel*, *Blount*.

MANUALIS *Lapis*, in natural history, the name of a stone found in America, of which Monardes relates that it has great virtues in curing chaps and cracks in the hands and feet; but he does not describe it.

MANUBIÆ, among the Romans, the spoils of the enemy, or rather the money made of the booty, when sold by the quæstor. *Pitisc.*

MANUCMANUC, in natural history, a name given by the people of the Philippine Islands to a very beautiful species of parrot, which is found very frequently wild in the woods there. It is of the same bigness with the common parrot, and is variegated with a great many different colours.

MANUCODIATA, in zoology, the name of the bird of paradise, as it is usually called in English; a bird of which many fabulous accounts have been propagated, as that it had no legs, that it took in no food, and lived only on the dews; that it was always on the wing, and had no other way of resting than as it hung in the air; that it was never taken alive, and that the male had a cavity in his back, which served for the female to lay her eggs, and hatch her young in; all which are wholly fabulous. The bird is a bird of prey, but of a peculiar kind, the use of whose long feathers is not well known. See Tab. of Birds, N°. 6. *Ray's* Ornithol. p. 55.

There are several species of this beautiful bird; Mr. Ray has reckoned eleven, and others have mentioned more, which were unknown to that author; but it is much to be questioned whether many of these are not rather the varieties of age and sex in the same species. The distinguishing character of these birds is their extremely long feathers which they carry behind. It is well known now that they feed on small birds, and build in the woods, perching upon trees like other birds, most of those now brought into Europe being killed while sitting. *Ray's* Ornitholog. p. 62.

MANULCA, in antiquity, that part of the *catapulta* to which the cord used in working it was fixed. *Pitisc.* See the article CATAPULTA, *Cycl.*

MANURE. See the article MANURING, *infra.*

MANURING (*Cycl.*)—Sea sand is often made use of by way of *manure*, in some parts of Cornwall, near the sea-shore. When the sand is notably shelly, that is, much mixed with the broken pieces of sea-shells, it is reckoned best. It is spread upon such land as is intended for wheat, or usually in the first crop of four, whatever be the grain; for after four crops it is the custom in Cornwall to leave the land six or seven years for pasture before it is tilled again; and the grass will be so good the first year, where this *manure* is used, as to be fit for mowing: This is called *mowing of gratten* by the people there. The Cornish acre is eight score yards, at eighteen foot to the yard. In one of these acres, the farmers bestow, according to the distance from the sea-shore, from three hundred sacks to one hundred, each sack containing thirteen gallons, which is called a horse load, the roads in many parts of this country being so bad, that they are forced to carry the sand on horseback from the water-side to the land, though eight or ten miles distant. In this case the sand costs them in the whole about eight pence a load. Where the lands lie very distant from the shore, and from all water-carriage, they bestow very little of this *manure*, but they do not care to be any where wholly without it. In some of these places they lay twenty load on an acre, and find a proportionable advantage from it. Where much sand is used, the corn is large and plentiful, and the straw little. Hence has grown the old Cornish phrase of *a bushel of corn to a peck of straw*; which is not miraculous in a place where the ears of barley are frequently found as long or longer than the stalks they grow on.

Where little of this sand is used, there is generally a great deal of straw, and but little and hungry ears of small grain. After the corn is taken off, the grass that naturally comes up is a white clover; and where the land is any thing deep, a red kind comes up among it. This is usually but short the first year, but it grows thick, and affords good feeding for the cattle; and they are found to thrive better, and give better milk than when they are fed on the high grass, which generally succeeds where there has been less sand used.

Another great advantage of the lands where much sand is used, is, that no snow lies upon them; there is a continual winter-spring, and an early harvest, usually six weeks before the neighbouring lands that do not use it in proper quantities; so that all the expence of procuring it in quantities, is many ways amply repaid to the farmers.

We have about Erith, and in many other places, the same sort of sand in great abundance in the Thames, that is used with this great advantage in Cornwall; and if it should be found on trial to answer as well, probably there would be found few places where this river would not afford it at some depth, or in some part of its bed. The coral sand of Falmouth is dredged up from under about a foot thickness of the Ouze; and perhaps in the Thames, where the bottom seems of another nature, the same sand, or some of equal efficacy, may be found underneath. The sand taken up out of the Thames at Erith, is used by the brick-makers, and they observe that the grass always grows patticularly fresh and strong about the edges of their heaps of it, and that clover naturally grows there among the other grass. Phil. Transf. N° 113.

In some counties of England, particularly in Oxfordshire, they use, by way of *Manure* for some of their lands, the cuttings and chippings of stone in the quarries, which is supposed to enrich the land by means of a salt that the stone contains, which being dissolved by the weather is imbibed by the earth. *Plot's* Oxfordshire, p. 249.

MANUS *Martis*, in botany, a name given by some authors to the common cinquefoil, or *quinque folium vulgare*. *Ger.* Emac. Ind. 2.

MAO, or *Mau*, in botany, a name by which some authors have called the *magna Indica*, or Indian mango tree. *Hort.* Mal. vol. 4. p. 1.

MAPLE, *Acer*, in botany, the name of a genus of trees, the characters of which are these: The flower is of the rosaceous kind, and is composed of several petals arranged in a circular form. The pistil arises from the cup, and finally becomes

comes a fruit compofed ufually of two, fometimes of three capfules, which are terminated by a foliaceous wing, and contain roundifh feeds.

The fpecies of *Maple* enumerated by Mr. Tournefort, are thefe: 1. The greater *Maple*, called the white mountain *Maple*, and by fome the plane tree. 2. The common great *Maple*, with variegated leaves. 3. The mountain great *Maple*, with deep green leaves, refembling thofe of the platanus. 4. The great *Maple*, with rounder and lefs jagged leaves, fuppofed to be the Italian opulus of fome authors. 5. The common or fmall *Maple*. 6. The trifoliate *Maple*. 7. The bindweed leaved climbing American *Maple*, with flowers of a fcarlet and gold colour. 8. The citron-leaved climbing American *Maple*, with blue fpiked flowers. 9. The purple-flowered climbing American *Maple*, with pfeudo-acacia leaves. *Tourn.* Inft. p. 615.

The feveral forts of this tree are eafily propagated by fowing the feeds, foon after they are ripe, in an open bed of common earth, covering them about half an inch thick with light fandy earth. The fpring following they will appear above ground, and will grow to a foot high the firft fummer. About the Michaelmas following they are to be removed, and planted at three feet diftance, in which place they may remain four years; and at that time they will be large enough to plant out into the places they are to ftand in.

The great *Maple* commonly, though very improperly called the *fycamore-tree*, is raifed very eafily in this manner, and is a very valuable tree for gentlemen who have plantations near the fea, as it bears the fpray of the falt water very well, and will defend all the reft if planted behind them.

The Virginian kinds may be propagated, either thus by fowing, or by laying down the young branches early in the fpring, giving them a little flit at a joint, by which means they will take fufficient root in a twelve-month to be tranfplanted out. *Miller's* Gard. Dict.

Maple *Sugar*, a kind of fugar made from a fpecies of the *Maple* called by Monfieur Sarazin, *Acer canadenfe facchariferum fructu minori*. Mr. Sarazin, a phyfician at Quebeck, intending to enquire at large into the nature of this fort of fugar, obferved that there were four fpecies of *Maple* common in the places where it was made, all which he fent over to the garden at Paris. One of thefe fpecies, diftinguifhed from the reft by the fmallnefs of its fruit, is called the fugar *Maple*; this grows to fixty or eighty foot high, and its juice, which is very redundant in the months of April and May, is eafily made into a very good fugar. They procure this juice from the tree by piercing a hole into the trunk, and placing veffels to receive it: This juice, being evaporated, yields about one twentieth part of its own weight in pure fugar. A middle-fized tree, of this fpecies, will yield fixty or eighty pints of this juice, without receiving any damage as to its growth; and much more than this may be drawn, but then the tree manifeftly fuffers for it.

Mr. Sarazin obferved fome very remarkable particulars in regard to the faccharine quality of this juice, without which it never had it in the proper perfection. 1. The tree at the time that the juice is drawn out, muft have its bottom covered with fnow; and if it is not naturally fo, the Indians know fo well the neceffity of it, that they always bring fnow from elfewhere, and heap it up round it. 2. This fnow muft afterwards be melted away by the fun-fhine, not gradually thawed by a warm air. 3. There muft have been a frofty night before the opening the hole in the trunk. It is remarkable that thefe circumftances are fuch as cuftom and experience alone could have pointed out, fince they feem contrary to reafon; and fo it is in many of the operations in chemiftry, where the moft feemingly rational means fail, while thofe which fhould feem quite contradictory to reafon fucceed. It is obferved, that if the juice of the *Maple* be not in a condition to become faccharine while the fnow lies at its root unthawed, that it almoft immediately becomes fo on the melting of the fnow, and its penetrating into the earth. Mem. Acad. Par. 1730.

MARACANA, in zoology, the name of a bird of the parrot kind, but larger than the common fpecies, and covered all over with bluifh-grey feathers. It is very common in the Brafils.

The natives alfo call another bird of the parrot kind by the fame name, which is of a fine green on the head, neck, and back, but the crown of the head looks a little bluifh; the tail is mixed of red and a bluifh-green; the under part being red, as is alfo the under part of the wings; at the origin of each wing, it has alfo a red fpot; and on each fide of the head a brown one. The noife this bird makes, is oe, oe, oe. *Marggrave's* Hift. Brafil.

MARANA, in botany, a name by which fome authors have called the ftramonium, or thorn apple, a plant kept in fome gardens. *Ger.* Emac. Ind. 2.

MARATHRUM, in botany, a name by which fome authors have called the common fœniculum or fennel. Id. ibid.

MARBASIS, in botany, a name given by fome to a kind of plant which they fay climbed up trees, and there hung down from their branches in form of long jointed and naked filaments.

The word feems to be only a corruption of the word *anabafis* of Pliny, which he calls alfo *ephedra*, and gives the fame characters to. It fhould feem that this is all an error, that no plant, fuch as they defcribe, ever exifted, but that the whole was founded on this: The hippuris, or horfetail, was diftinguifhed by having naked and flender ftalks full of joints; it thence became natural for the Greeks to call by the fame name any thing that was in like manner compofed of fuch long and naked filaments; and the common *ufnea*, or hairy tree mofs, which hangs down from the branches of large foreft trees, is more like a horfe's tail by far than the plant commonly fo called is: it is not wonderful, therefore, that it fhould be called by the fame name.

The Greeks, from the watery places in which the common horfetail ufually grows, called it *ephydron*; and this word mif-fpelt feems to have made the *ephedra* of Pliny in this place. If this was found hanging from the branches of trees, and no body had ever mentioned its growing on the trees themfelves, it is no wonder that fo carelefs a writer as Pliny fhould defcribe it as growing on the ground near the roots of trees, and climbing up their trunks, and then hanging down from their branches in form of horfes tails.

This feems to account for the whole that Pliny has left us concerning this plant; and it is very evident, that the common *ufnea*, or hairy tree mofs, very well agrees with his defcription of the *ephedra* and *anabafis*, though no other plant does. He fays it hangs down from the large branches in form of numerous hairy threads, which are naked or wholly without leaves. The *Marbafis* of the antients feems, therefore, to mean our *ufnea*. See the article Usnea.

MARBLE, *Marmor*, (*Cycl.*) in natural hiftory. *Marbles* make a peculiar genus of foffils, the characters of which are thefe: They are bright and beautiful ftones, compofed of fmall feparate concretions, moderately hard, not giving fire with fteel, and fermenting with and foluble in acid menftrua, and calcining in a flight fire.

By thefe characters the *Marbles*, properly fo called, are diftinguifhed from the porphiries and granites, which are properly ftones of a very different kind, being compofed of very different particles, and exhibiting contrary properties. See the article Porphiritis, &c.

The *Marbles* are a genus of bodies fuppofed to be very well known, becaufe feen every day, and in common ufe; but they are in reality, notwithftanding that, perhaps one of the moft confufed, and leaft underftood of all the bodies of this kind. The people who work upon them, know nothing more of them than that this will, and that will not receive a polifh in a high degree; and that this may be worked, and another refufes the tools; and the men of fcience have confidered them even lefs than thefe.

The *Marbles* were one of thofe fets of bodies that the antients were well acquainted with, and it may give no fmall light into their true hiftory, to pay a ftrict attention to what they have left us concerning them, and enquire which of thofe in ufe among them are known to us, and which loft, and by what names we now call their *Augufteum*, *Tiberianum*, *Luculleum*, and the reft. This may ferve to give a certain account of what they knew, and perhaps may point out to the builder, ftatuary, and phyfician, fome new ufes, at leaft new to us, of many of them. *Hill's* Hift. of Foff. p. 461. See the article Luculleum, Augusteum, &c.

Ægyptian Marble, a name given by our artificers to a very beautiful green-and-white *Marble*, greatly in ufe among us, and brought in great quantities from Egypt and other places. It was alfo in frequent ufe, and in great efteem among the Romans, who received it alfo from Egypt, and diftinguifhed too lightly two kinds of it, from the different difpofition and order of its variegations, and honoured them with the names of two of their emperors in whofe reign they were firft brought into ufe. Thefe were the *marmor Augufteum* and *Tiberianum*. Thofe pieces in which the variegations were waved and thrown into arches and circular figures, they called the *Auguftan*, and thofe which were marked with more diffufed and fcattered veins, they called the *Tiberian*. Thefe were the whole differences between the two; and if we were to acknowledge different fpecies from fuch differences as thefe, we muft allow almoft as many different fpecies as we fee blocks of *Marble*. *Hill's* Hift. Foff. p. 482.

This kind of *Marble*, in all its appearances, is, tho' a very beautiful yet a very rude, irregular, and various mafs. It is of a firm compact texture, and moderately heavy, and may be properly called a green *Marble* variegated with white, for thofe are its two confpicuous colours; but it has thefe mixed in fo great a variety as to afford lights and fhades of a vaft number of degrees of colours. It has befides thefe, alfo many other variegations of a dufky colour approaching to black. It is very bright and glittering when frefh broken, and varioufly fo in its various parts. In the white parts it is brighteft of all, and the other colours are more lucid as they are paler, or nearer approach to the white. It has, however, among its other particles, fome of a very beautiful green foliaceous talc. The whole is capable of a good polifh, and is common

mon in tables, &c. in the houfes of the polite part of the world. *Hill's* Hift. Foff. p. 481.

Coralloide MARBLE, in natural hiftory, the name given by authors to fuch *Marbles* as have fpecimens of the marine corals or bodies of that kind immerfed in them, as the fea fhells are buried in, and make a part of the body of others.

There are feveral fpecies of *Marble* fubject to hold thefe bodies, but we have in England principally two in ufe, the one of a greyifh black, the other of a fine deep jetty black. The firft is found in many parts of Derbyfhire, and the corals it contains are of the porus kind, and of one of the moft elegant fpecies in the world; they are lodged in it at all angles, and in all directions, and are in general about an inch and half long, and three quarters of an inch broad, though fome are much larger, and others fmaller. They are compofed of longitudinal plates, very fine and thin, and of a fnow white, ranged in diftinct orders, and finely interfperfed at fmall diftances, with thin tranfverfe plates; the whole internal part of the coral being thus divided into a fort of fquare cells. This net-like divifion runs through about three-fourths of the body, but the top has only the longitudinal plates without the tranfverfe ones. It is plain that thefe before they were received into the bed of marble, had been fuftained in a fluid containing a very beautiful greyifh white fpar, for the net-like plexus of the bed is full of this matter; but the open part at top having no plates for the retaining this matter, has remained empty till received into the *Marble*, and is there found filled up with the common blackifh matter of the reft of the ftratum. It is an extremely beautiful fubftance when polifhed, and is ufed in many ornamental works. It is found in many parts of Derbyfhire and in Wales.

The other, or black *coralloide Marble*, is alfo a very beautiful fpecies; it is a very clofe compact fubftance, and of a fine even texture, very hard, of a deep jetty black, and capable of a high polifh. It is elegantly variegated with fair and perfect fpecimens of a coralloide porus, approaching to the nature of the former, but fmaller and of a lefs elegant texture; and among thefe has ufually a great number of fea fhells, both of the turbinated and bivalve kinds. Thefe are lodged in various directions, and all of them, the corals as well as the fhells, are of a pure fnow white; and as the matter and texture of the others plainly fhewed that they had been filled with fpar before they were immerfed into the bed of *Marble*; thefe, on the other hand, retaining now no part of their original texture, though exactly their external figure, but being all made up of the fame plain white fpar, plainly fhew that they were lodged in the *Marble* empty, and in their own native ftate; for the cavities both of the corals and fhells are all nicely filled with the matter of the *Marble*; but they have now no coralline nor teftaceous matter about them, but in tract of time have plainly perifhed, and the cavities they left in the hard and fmooth mafs of the *Marble* have been nicely and finely filled up with this fpar, which therefore now as perfectly reprefents their figures, as if themfelves were there. *Hill's* Hift. Foff. p. 473.

It is found in great plenty in many parts of Ireland, particularly about Kilkenny, and is brought in great quantities to London, and ufed about chimney-pieces, and other ornamental works, and is commonly known among the artificers by the name of Kilkenny *Marble*.

Alabandium MARMOR, a name given by the antients to a very remarkably gloffy fpecies of black marble, dug near a city of that name in Caria, and much ufed in building among the Romans.

Caryftium MARMOR, a name given by the antients to a fpecies of marble, dug in the ifland of that name, and much ufed in ornamenting the public buildings; it was of a beautiful green, deeper than the Tiberian and Auguftan marble, and without the white variegations. We meet with it fometimes among antient remains; and the Italian antiquaries particularly mean this, by a name alfo in ufe among us, and proftituted to every other fpecies of green marble, the *verde antiquo*.

Tiberianum MARMOR. See the article TIBERIANUM *Marmor*.

Derby MARBLE, among our artificers, a name given to a very beautiful fpecies of *Marble*, found in many parts of Derbyfhire, and frequently worked into chimney-pieces in London.

It is a very fingular and beautiful fpecies; its conftituent matter is a pale, fine, whitifh brown *Marble*, of a fine clofe texture, and very bright and glittering hue: This is fo full of entrochi, that they make more than half the fubftance of the mafs; and thefe cutting in different directions, and taking a fine polifh, add greatly to the beauty of the whole, when wrought. *Hill's* Hift. of Foff. p. 479.

The various forms in which thefe bodies appear in the ftone, when cut, might give a fufpicion that many of them were fome other foffile; but this is only owing to their lying in all directions in the mafs; but when nicely examined, the oddeft of them will be found to be no other than what a fingle common entrochus may be cut into. They are of all fizes, from the thicknefs of a large pin, to half an inch or more.

Italian MARBLE. See the article ITALIAN *Marble*.

Kilkenny MARBLE. See the article *Coralloide* MARBLE, *fupra*.

Namur MARBLE. See the article NAMUR.

Colouring of MARBLE. The colouring of *Marbles* is a nice art, and in order to fucceed in it, the pieces of *Marble*, on which the experiments are tried, muft be well polifhed, and clear from the leaft fpot or vein. The harder the *Marble* is, the better it will bear the heat neceffary in the operation; therefore alabafter, and the common foft white *Marble*, are very improper to perform thefe operations upon.

Heat is always neceffary for the opening the pores of the *Marble*, fo as to render it fit to receive the colours; but the *Marble* muft never be made red hot, for then the texture of the *Marble* itfelf is injured, and the colours are burnt, and lofe their beauty. Too fmall a degree of heat is as bad as too great; for, in this cafe, though the *Marble* receive the colour, it will not be fixed in it, nor ftrike deep enough. Some colours will ftrike, even cold, but they are never fo well funk in as when a juft degree of heat is ufed. The proper degree is that which, without making the *Marble* red, will make the liquor boil upon its furface. The menftruums ufed to ftrike in the colours, muft be varied according to the nature of the colour to be ufed. A lixivium made with horfe's or dog's urine, with four parts quick-lime, and one part pot-afhes, is excellent for fome colours; common lye of wood-afhes does very well for others: For fome, fpirit of wine is beft; and finally, for others, oily liquors, or common white wine.

The colours which have been found to fucceed beft with the peculiar menftruums, are thefe: Stone blue diffolved in fix times the quantity of fpirit of wine, or of the urinous lixivium; and that colour which the painters call litmoufe, diffolved in common lye of wood-afhes. An extract of faffron, and that colour made of buckthorn berries, and called by the painters, fap green, both fucceed well diffolved in urine and quick-lime, and tolerably well in fpirit of wine. Vermillion, and a fine powder of cochineal, fucceed alfo very well in the fame liquors. Dragons blood fucceeds very well in fpirit of wine, as does alfo a tincture of logwood in the fame fpirit. Alkanet root gives a fine colour, but the only menftruum to be ufed for this is oil of turpentine; for neither fpirit of wine, nor any lixivium, will do with it. There is another kind of *fanguis draconis*, called dragon's blood in tears, which, mixed with urine alone, gives a very elegant colour. Phil. Tranf. N°. 268.

Befide thefe mixtures of colours and menftruums, there are fome colours which are to be laid on dry and unmixed. Thefe are dragons blood, of the pureft kind, for a red; gamboge for a yellow, green wax for a green, common brimftone, pitch and turpentine for a brown colour. The *Marble*, for thefe experiments, muft be made confiderably hot, and then the colours are to be rubbed on dry in the lump. Some of thefe colours, when once given, remain immutable, others are eafily changed or deftroyed. Thus the red colour given by dragons blood, or by a decoction of logwood, will be wholly taken away by oil of tartar, and the polifh of the *Marble* not hurt by it.

A fine gold colour is given in the following manner: Take crude fal armoniac, vitriol and verdegreafe, of each equal quantities; white vitriol fucceeds beft, and all muft be thoroughly mixed in fine powder.

The ftaining of *Marble* to all the degrees of red, or yellow, by folutions of dragons blood or gamboge, may be done by reducing thefe gums to powder, and grinding them, with the fpirit of wine, in a glafs mortar; but for fmaller attempts, no method is fo good as the mixing a little of either of thefe powders with fpirit of wine in a filver fpoon, and holding it over burning charcoal. By this means a fine tincture will be extracted, and with a pencil dipped in this, the fineft traces may be made on the *Marble*, while cold, which, on the heating it afterwards, either on fand, or in a baker's oven, will all fink very deep, and remain perfectly diftinct in the ftone. It is very eafy to make the ground colour of the *Marble* red or yellow by this means, and leave white veins in it. This is to be done by covering the places where the whitenefs is to remain with fome white paint, or even with two or three doubles only of paper, either of which will prevent the colour from penetrating in that part. All the degrees of red are to be given to *Marble* by means of this gum alone; a flight tincture of it, without the affiftance of heat to the *Marble*, gives only a pale flefh colour, but the ftronger tinctures give it yet deeper; to this the affiftance of heat adds yet greatly; and finally the addition of a little pitch to the tincture

tincture gives it a tendency to blacknefs, or any degree of deep red that is defired.

A blue colour may be given alfo to *Marble* by diffolving turnfol in a lixivium of lime and urine, or in the volatile fpirit of urine; but this has always a tendency to purple, whether made by the one or the other of thefe ways. A better blue, and ufed in an eafier manner, is furnifhed by the canary turnfol, a fubftance well known among the dyers: This needs only to be diffolved in water, and drawn on the place with a pencil; this penetrates very deep into the *Marble*, and the colour may be encreafed by drawing the pencil wetted afrefh feveral times over the fame lines. This colour is fubject to fpread and diffufe itfelf irregularly; but it may be kept in regular bounds, by circumfcribing its lines with beds of wax, or any other fuch fubftance. It is to be obferved, that this colour fhould always be laid on cold, and no heat given even afterwards to the *Marble*; and one great advantage of this colour is, that it is therefore eafily added to *Marbles* already ftained with any other colours, and it is a very beautiful tinge, and lafts a long time. Mem. Acad. Par. 1732.

MARBLE *Colour*. To give this variegated colour to glafs is a very eafy operation: There needs no more than to put cryftal frit into a pot in the furnace, and to work it before it has ftood the ufual time to purify in the fire. *Neri's* Art of Glafs, p. 99.

MARBLE *Wood*, a name given by the people of fome parts of America to the *lignum rhodium*, or rofe-wood, from the heart of the tree being fometimes variegated like *Marble*.

MARBLED (*Cycl.*)—MARBLED *China Ware*, a name given by many to a fpecies of porcelain, or China-ware which feems to be full of cemented flaws. It is called by the Chinefe, who are very fond of it, *tfou tchi*.

It is generally plain white, fometimes blue, and has exactly the appearance of a piece of China which had been firft broken, and then had all the pieces cemented in their places again, and covered with the original varnifh. The manner of preparing it is eafy, and might be imitated with us. Inftead of the common varnifh of the China-ware, which is made of what they call oil of ftone and oil of fern mixed together. They cover this with a fimple thing made only of a fort of coarfe agates, calcined to a white powder, and feparated from the groffer parts by means of water, after long grinding in mortars. When the powder has been thus prepared, it is left moift, or in form of a fort of cream, with the laft water that is fuffered to remain in it, and this is ufed as the varnifh. Our cryftal would ferve fully as well as thefe coarfe agates, and the method of preparation is perfectly eafy. Obf. fur les Cout. de l'Afie.

The occafion of the fingular appearance of this fort of Porcelain is, that the varnifh never fpreads evenly, but runs into ridges and veins. Thefe often run naturally into a fort of mofaic work, which can fcarce be taken for the effect of chance. If the *marbled* China be defired blue, they firft give it a general coat of this colour, by dipping the veffel into a blue varnifh; and when this is thoroughly dry, they add another coat of this agate oil.

MARCASITE, (*Cycl.*) in natural hiftory, a name ufed in a very vague fenfe by many writers upon foffils, but reftrain'd by Dr. Hill to be the name of a peculiar genus of foffils, the characters of which are, that they are compound inflammable metallic bodies, naturally conftituting whole ftrata; of a folid and firm fubftance, of an obfcurely and irregularly foliaceous ftructure, and of a bright glittering appearance, very freely and readily giving fire with fteel, not fermenting with acid menftruums, and when put into the fire, yielding a deep blue flame, and finally calcining into a purple powder.

Though the natural difpofition of thefe bodies be to form whole ftrata, and that they are moft ufually found in this ftate, yet they are at times found in loofe maffes, as many, even of the ftones of ftrata, at times are. They are fubject alfo, by their frequent admixture with adventitious matter, the ores of metals, and other foffile bodies, to fuch various external appearances, that their varieties are almoft innumerable, and moft of them are very beautiful: But tho' thefe accidental differences are fo very numerous, the genuine fpecies are very few, the naturalift allowing only three. Thefe are, 1. The bright filver-colour'd *Marcafite*. 2. The bright gold-colour'd *Marcafite*. And 3. The pale heavy dead white *Marcafite*.

The firft fpecies ufually conftitutes ftrata of great extent, and of about a foot in thicknefs; very often much lefs, but fcarce ever much more: It is compofed of a number of foliaceous flakes, not regularly difpofed, but oddly contorted and waved, and often folding round one another; though fometimes this ftructure is lefs diftinct, and the whole feems run into one folid mafs. Its colour is extremely bright, very like filver, but more glittering. This is its common and its more pure ftate; but it is liable to a vaft number of varieties. Sometimes it contains a large quantity of the ore of lead or tin, and very often a dufky brown ferrugineous matter is intimately mixed with it; at other times many of the angular and regularly figured phlogoniæ are immerfed in it, and feem to make a part of its very ftructure; and fometimes where it has room, its conftituent flakes rife on its furface in feveral conjunct feries, and form a very elegant foliaceous top to it. Nor is this all the difference of appearance it puts on; for very often, where there has not been a fufficient quantity of it to form itfelf into any figure alone, it is found depofited in fpecks, or flat cakes, of a more or lefs complex, but always of a flaky ftructure, on ftones or ores of various kinds; and frequently, befide its native filvery white, it has all the rainbow-colours on its different parts, as differently turned to the light. *Hill's* Hift. of Foff. p. 609.

The *golden Marcafite* is a more beautiful fubftance than the former: It is of a lefs firm or compact ftructure than the others, and is ufually found in very long but very thin ftrata, and is of an extremely bright and glittering appearance, and is fometimes found in large and mif-fhapen nodules, or loofe maffes. It is liable to all the accidental varieties that the former is, and in many of them makes a very elegant appearance. The third, or dead white kind, is the hardeft and heavieft of all. It is, in its more ufual and natural appearance, of much lefs beauty than the former kinds, but it is, like them, fubject to various accidents, under fome of which its makes a very gay and fplendid appearance. It, like the reft, fometimes forms compleat ftrata, fometimes detach'd nodules; but its moft ufual appearance is in the horizontal cavities of other ftrata; in thefe it often forms a fort of baftard ftratum of many yards continuance, and frequently of very confiderable thicknefs, for it almoft always fills up the whole vacuity, and that fo clofely as feldom to leave room for any foliaceous fhoots at its furface, or protuberances at its edges, but forms a plain mafs like that of a metal melted and poured into the place. It is of the fmootheft furface of all the *Marcafites*, and is fomewhat foft to the touch, and in colour refembles tarnifhed pewter.

This is its common appearance, but it fometimes fhews itfelf like the reft in fmall patches on the furfaces of ftones, and is there often very beautifully foliated; it is liable alfo to all the accidents of the other kinds.

The *Marcafites* are all found in great plenty in the Englifh and German mines. Devonfhire and Cornwall afford vaft quantities of them; and very beautiful ones are found in Derbyfhire. They often contain the feveral metals, but the quantity of fulphur has yet baffled all the attempts that have been made to work them to advantage. *Hill*, Hift. of Foff. p. 610.

Avifenna mentions four kinds of *Marcafite*; the golden, the filvery, the braffy, and the iron *Marcafite*. He does not pretend that the two firft contain really the metals whofe names they bear, but fays they are fo called from their likenefs in colour, and that they are thought by fome to poffefs, in part, their virtues. Diofcorides mentions only one kind, that is, the braffy pyrites or *Marcafite*. This is, of all others, the moft common; and the preference is given by this author to fuch of it as is of a bright brafs colour, and fuch as, when ftruck againft fteel, yields the largeft fparks. This is the kind called by Avifenna and Serapio, *Marcafita nubafi*, and it is called by the Perfians, *hagiar alruxenani*, that is, the ftone of light or brightnefs, there being a very vivid and fparkling luftre in this ftone when newly broken. The antients ufed to calcine it, and then made it an ingredient in their feveral compofitions for difeafes of the eyes. The calcining it renders it a fort of colcothar of vitriol, for the fulphureous parts burn away in the operation, and leave only the *caput mortuum* of the vitriol behind; fome have fuppofed it called *lapis lucis*, from its reftoring light to the eyes; but this is a very far fetch'd etymology.

The firft opinion of the world, in regard to this glittering fubftance, was, that it was almoft all gold or filver, according to the colour: But the error of this opinion being foon difcovered by trials, there grew another contrary one, that *Marcafite* never contained any metal at all. This is, in general, true of our *Marcafites*, but it is not to be extended into a general rule for thofe of all the world. The fearchers after royal mines are not to throw away all thefe fubftances as ufelefs, wherever they find them. For Alonfo Barba, a very great judge of thefe things, and himfelf very converfant in mines, affures us, that the *Marcafites* of the mines of Montferrat *en los chicas* contain ufually one half filver: And in the mines of Potofi there is great plenty of a *Marcafite*, in which there is embodied a large quantity of the black filver ore, well known there, and efteemed one of the richeft kinds, except the native filver. They always are glad to find this *Marcafite* vein, it being efteemed a proof, that the black ore is very rich in filver. They make the fame fort of obfervation in regard to orpiment and gold, that they do in regard to *Marcafite* and filver; that the orpiment ufually contains itfelf fome gold, and is a certain fign that there is gold in the neighbourhood wherever it is found. *Alonfo Barba* de Met.

MARCH, (*Cycl.*) in military affairs, is in general the fteps made in marching, or the moving of a body of men from one place to another.

But the beat of the drum, when the foldiers are upon *March*, or beginning to march, is likewife called the *March*. It is likewife a word of command, when a battalion is to alter its difpofition.

To *march* is to move from one place to another. The orders being given the evening before a *March*, that the drums beat at a certain hour, the foldiers are then ready drawn up at their ftandards and colours, in fquadrons or battalions, ready to begin their *march*.

As

As many accidents may happen in the *March* of an army; as defiles, marshes, woods, and the like, it is the prudence of a general to order his *March* accordingly, and to take care that the columns of his army have a free communication one with the other. The *March* of an army is composed of an advance guard, the main body, and the rear guard, and is sometimes in two, four, six, or eight columns, according as the ground will allow.

MARCH, *Marchia*, in our old writers, is used for a limit or border. Thus we read of the *Marches*, between England and Wales; or England and Scotland; which last are divided into *West* and *Middle Marches*. And the word is used generally for the precincts of the king's dominions, in 24 Hen. 8. c. 12. Terms of Law.

The word comes from the German *March*, i. e. *Limes*; or from the French *Marque*, i. e. *Signum*, used for the marks or signs to distinguish between two countries or territories. *Blount*, *Cowel*.

MARCHANTIA, *Liverwort*, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: It is of the nature of what we generally call the *lichens* or *liverworts*, and produces male and female flowers on the different parts of the same plants.

The male flower stands on a long erect peduncle, which arises from a sort of cup or case on the plant. The cup is a common perianthium, of the peltated kind, and divided into four, five, or ten parts, every segment having its edges depressed, and all being of the same size. This perianthium is large, and contains under it as many flowers as there are segments of it. Each flower is monopetalous, of a turbinated form, standing erect, and somewhat shorter than the cup. The stamen in each flower is single, and is a slender filament, longer than the flower. The apex or anthera, sustained on this stamen, is of an oval figure, and is commonly found burst at the top into as many parts as there are segments in the perianthium, be that four, five, or ten. The farina within it is affixed to a sort of hairyness.

The female flower has no pedicle; the cup is a one-leav'd perianthium, erect, open at the top, and undivided, consisting of a sort of membranaceous ring, which does not fall off till the seeds are ripened. There is no other flower but this cup, which contains several naked seeds in the bottom; they are of a roundish compressed figure. Dillenius has comprised this genus under the general term *lichen*; and Micheli has called different species of it by the different names of *lunularia* and *hepatica*; and, according to these distinctions, the *Marchantia* is the name of those species which have the cup of the male flower divided into eight or ten segments, which are flat, and do not enclose the flowers. The *hepatica* is the name of those species which have the male cup, of a conic figure, divided into five segments, and those bending inwards, and the *lunularia* of those species which have the male cup, of a cruciform figure, with curled segments, enclosing the flowers. *Linnæi* Gen. Plan. p. 506. *Micheli* Nov. Gen. Plant.

Livervort is said to be aperient, attenuant, and resolvent, and therefore good in obstructions of the liver, and other viscera; but at present is only used as an ingredient in some compositions.

MARCHERS, or *Lords* MARCHERS, in our old writers, noblemen that lived on the marches of Wales, or Scotland. These, in times past, according to Cambden, had their laws, and power of life and death, &c. like petty kings. But such powers were abolished by the stat. 27 Hen. 8. c. 26. and 1 Edw. 6. c. 10. Terms of Law, *Blount*.

MARCHIONIS *Pulvis*, a term used for a certain compound powder, prescribed in the Leyden Dispensatory, and greatly recommended by many as an anti-epileptic and absorbent.

The ingredients are male piony root, half an ounce, wood of misletoe of the oak, raspings of ivory, elks hoof, spodium, the tooth of the unicorn fish, or, in its stead, the antlers of the stag's horn, red and white coral, and pearls, of each a dram. These are all to be rubbed into a powder, with twenty leaves of pure gold, and given half a dram twice a day.

MARCULUS, among the Romans, a knocker, or instrument of iron to knock at the doors with. *Pitisc.* Lex. Ant.

MARDAC, in the materia medica of the antients, a name given by some to litharge. The Arabian writers have sometimes called it by this name, and sometimes by that of *mardesengi*. Many of their commentators have thought that they meant two different substances by these two names; but it does not appear to be truly the case, the two words standing, in different writers, for the same thing. Avisenna has given us a chapter on *Mardac*, in which he has translated the chapter of Dioscorides on litharge: And Serapio has given us a chapter on the *merdesengi*, in which he has given us an account of the same substance, under the terms that Galen uses for the description of litharge, and even quotes him for the account.

MARES, *Equa*, in zoology, the female of the horse kind. See the articles EQUUS and HORSE.

No *Mares* in the world are better for breeding out of of than the English, provided they are properly chosen for the sort of horse intended to be bred. The *Mare*, whatever sort of horse is intended to be raised from her, should be perfectly found, and as free from all defects as the stallion. They should have no splaint, spavin nor curb about them; for the colt will certainly take after them if they have. The highest spirited *Mares* are best, and, in general, if there be any natural defect in the *Mare*, it should be remedied in the stallion; and if any in the stallion, it should be remedied in the *Mare*, as much as possible, in order to the having good colts.

The particular directions regarding the kinds of horses to be bred, are these: If for the manege, or pads, the *Mares* should have their heads well set on, and their breasts broad; their legs not too long, their eyes bright and sparkling, and the bodies large enough, that the foal may have room to lie in their belly. They should be of a good and gentle disposition, and their motions easy and graceful: The more good qualities the *Mares* have, the better, in general, the colts will prove.

If the owner would breed for racing, or for hunting, the *Mares* must be chosen lighter, with short backs and long sides; their legs must be longer, and the breast not so broad; and such should always be chosen as have good blood in their veins. If the speed and wind of any particular *Mare* have been tried, and found good, there is the more certainty of a good colt from her: But she should be in full health and vigour at the time, and not above seven years old, or eight at the utmost. The younger the breeders are, the better, in general, the colts will be.

A *Mare* may be covered any time after she is two years old; but the best time is after she is four; at this age, or between this and seven, she will nourish a colt best of all; and though she will breed till she is thirteen, yet it is generally observed, that when she is past ten, the colts bred from her are dull and heavy. People who regard the moon, in these cases, will have their *Mares* covered only between the end of the first quarter and the full; they pretend that these colts will be the most strong and vigorous, but that those begot in the waning of the moon, will always be weakly and tender. A much more essential caution, however, is, that before the *Mare* is to be covered, she should be taken into the house for six weeks, at least, and fed well with good hay and oats, well sifted, to give her strength to go through the operation. If there is any reason to suspect that the *Mare* will not conceive, the best method to insure it is to let her blood in the neck, about six days before she is cover'd: The quantity of blood taken away should be about two quarts, or somewhat less. It is a general custom to open the veins on both sides the neck for this, taking half the quantity from each, but this is trifling.

The method of covering, so as to make it most sure to succeed, is this: The *Mare* is to be brought into some open place, and tied to a post; and the stallion is to leap her in the morning fasting, and as soon as he dismounts, a pail of cold water is to be thrown upon her, to make her shrink in and retain the seed. She is then to be taken away out of hearing of the horse, and is neither to eat or drink for four or five hours after.

It may be known if she stands to her covering, by her keeping a good stomach, and not neighing at the sight of a horse. Some, to make it quite secure, put the *Mare* and horse together in an empty house every night, for four or five nights, taking away the horse in the morning, and feeding him very liberally, and the *Mare* very sparingly, and particularly giving her very little water.

There must be proper care taken of her after covering. The same method of feeding her with good hay, and sifted oats, must be continued three weeks, or a month, and she must be kept within doors, and without any exercise; her stable must be kept very clean, and her feet pared, and with thin shoes on. After this she may be turned out for the summer season, and only taken up in September, in order to be kept well fed till she foals. If there be great difficulty in her foaling, or the secundine be retained, the method is to hold her nostrils, so that she cannot breathe; and if this does not do, a decoction of madder-root, or of fennel, in water, with a mixture of ale or wine, is found very effectual.

When the whole is over, the *Mare* is very apt to eat up her secundine; but this should be prevented, for it is an unnatural food for her, and will injure her health. When she has licked her foal, some persons should stroak and milk her before the foal sucks. This will make the milk come down in greater plenty, and will prevent it from clotting into lumps, or from disagreeing with the young creature's stomach. It often happens, that the milk clods in the udder, and the foal, being able to get none out, the *Mare* is supposed to be dry; and in consequence of this supposition, she actually becomes so. But the remedy is easy. Let as much milk as can be got from her be boiled with some lavender flowers, and the udder bathed thoroughly with it warm, several times a day: If no milk, or not enough can be obtained from her, other milk or common water will do; for the principal effect is from the heat of the liquor, and the virtue of the lavender, which breaks the clods and lumps, and then the foal's sucking more as it grows stronger, will prevent the like accident for the future.

The water given the *Mare* for the first month after foaling, must be what the dealers in horses call the white mash, that is,

is, bran and water, ftirred together till the liquor is white: A month after foaling a decoction of brimftone and favin will be very proper; and will give ftrength to the colt.

After this the *Mare* may be put to any moderate exercife, as harrowing, or the like, and both fhe and the colt will be the better for it; only care is to be taken that fhe do not let the colt fuck while fhe is hot.

Many are of opinion, that the winter is a very bad time for a *Mare* to be foaling; but though there is fcarcity of grafs, the *Mare* may be houfed at this time, and well fed with hard meat, and, in this cafe, it will prove better both for her and the colt; he will be better limbed and ftronger than if bred at grafs. See the article FOAL.

MARECA, in zoology, the name of a Brafilian fpecies of duck, much valued there at table. It is of the fhape of our duck. Its head is grey, but has a beautiful red fpot on each fide, at the infertion of the beak, and a whitenefs in the lower part under the eyes. Its breaft and belly are of the colour of frefh cut oak, variegated with black fpots. Its legs and feet are black. Its tail grey; and its wings elegantly variegated with grey and brown; but they have in the middle a large mixture of that gloffy green which we fee in the necks of our drakes. There is, befide this, another fpecies of the *Mareca*, which is of a dufky olive-colour'd brown on the back, white on the throat, and grey on the breaft and belly, and very remarkable for the fine bright red colour of its feet. *Marggrave*, Hift. Brafil.

MARENA, in zoology, the name of a fifh of the harengiform kind, much approaching to the nature of the common pilchard; but differing from it in that it has not the ferrated longitudinal line under the belly, and lives in lakes, not in the ocean. It feldom arrives to more than five inches in length; its back is blackifh, and its fides white and filvery, and its fcales are very loofe, and eafily rubbed off. It is a better tafted fifh than the pilchard, and its flefh is firmer. *Willughby*, Hift. Pifc. p. 229.

MARGA, *Marle*. See the article MARLE.

MARGEN, in the materia medica, a name ufed by fome of the later Greek writers to exprefs red coral. It is founded on an error, however, the word *Margen* being made from the Arabian *margian*, which does not fignify coral, but a purple fea wrack, or fucus, ufed in dying. See the article MARGIAN.

MARGENSTEIN, in natural hiftory, a name given by the German writers to a fort of indurated marle, which while in the ftrata is nearly of the hardnefs of ftone; but when laid on the furface of the earth, and expofed to the wind and rain, foon diffolves, and enters the pores of the ground, enriching the foil to a very great degree. We have the fame fort of ftony marle in fome parts of England, only that ours is lefs hard, and yet takes more time to break and diffolve in the air. They are both moft proper for lands of a loofe loamy nature, and keep them in heart a long time. *Swedenborg*, de Rebus Natural.

MARGGRAVIA, in botany, the name of a genus of plants, the characters of which are thefe: The perianthium is compofed of fix fcales, difpofed in oppofite pairs, and the fmaller placed below the others. The flower is very fingular, it confifts of one petal, and is of a conic oval form, every where whole and perfectly clofed at the mouth; this never opens, but, when it has ftood a fmall time, is thruft off at the bafe by the other parts of the fructification. The ftamina are numerous, fhort, and expanded filaments; the antheræ are large, erect, and of an oval figure; the germen of the piftil is oval; there is no ftyle, and the ftigma is obfolete. The fruit is a globofe berry, having only one cell, in which there are numerous very fmall feeds. Befide the flowers there is fomething very fingular in the umbels of this plant: In the middle of thefe there ftand a number of oblong feffile bodies of a wonderful figure; they are compofed of one leaf with an open mouth, and are bent downwards, and open at the bafe. Thefe are not flowers, but mere excretory glands for the plant, thus oddly fituated. *Linnæi* Gen. Plant. p. 282. *Plumier* Gen. p. 29.

MARGIAN, in botany, a name given by fome of the antient writers, particularly the Arabian phyficians, to the plant called by others *argina* or *arginem*. This is defcribed to be a purple fea plant. Some have fuppofed that cochineal was meant by this word, but that is an error. Others have come fomewhat nearer, in fuppofing it to be the name of coral; but as the antients have faid that it was ufed in dying, it could not be coral; and indeed there is no other plant that it can mean, but that fucus ufed by the Greeks in dying, and called *fucus porphyrizon*, or the purple dying fea plant. See the articles ARGINA and FUCUS.

MARIGOLD, in botany. See the article MARYGOLD.

MARQUES *de Ladre*, in the manege. See the article DULL.

MARINE-*Barometer*. See the article BAROMETER, *Cycl.*

MARINE *Remains*, a term ufed by many authors to exprefs the fhells of fea fifhes, and parts of cruftaceous and other fea animals, found in digging at great depths in the earth, or on the tops of high mountains. Their being lodged in thefe places, is an evident and unqueftionable proof of the feas having once been there, fince it muft have covered thofe places where it has left its productions.

It has been a favourite fyftem with many, and particularly with the late Dr. Woodward, that all thefe marine bodies were brought to the places where they now lie, by the waters of the univerfal deluge; which, as we are informed by holy writ, covered the whole furface of the globe, and even the higheft mountains. But though this is a very ready expedient to account for many of the natural phænomena, yet there are evident proofs that it cannot have been the caufe of all that is attributed to it; and there muft neceffarily have been fome other caufe of many of thefe remains having been placed where we now find them. Neither does the opinion of fome particular authors, that partial inundations of different places have left thefe *marine* bodies behind them at the recefs of the waters, feem fufficient to account for the multitudes of thefe remains, many of which we find thrown upon places inacceffible to fuch floods. *Moro* de Cruftaceis in Montib. deprehenf.

Signior Moro has attempted to account for thefe phænomena on a new plan of reafoning. He obferves, that it is the beft bafis of argument to begin from facts; and that if we can certainly find how fome part of thefe animal remains come to be depofited at fuch great diftances from their natural refidence, we may very rationally conclude, that by the fame means, be they what they will, all the reft were alfo brought thither. He adds, that the earth, once the bottom of the fea, or the level furface of a plain, may be, and frequently has been, in the memory of man, raifed up into a mountain by fubterranean fires, earthquakes, and volcanos. He mentions the famous inftance of the new ifland raifed out of the bottom of the fea near Santorini in the year 1707, which became of a circumference not lefs than fix miles, and of the new mountain raifed near Puzzoli in 1538.

Thefe and many other like facts, prove that the origin of mountains and iflands may have been fuch, and that the matter they confift of may have been the fame with what was once the bottom of the fea; and that the *marine* bodies found in thefe mountains, were fuch as were living, or remaining of living fifh at the time when the iflands or mountains were fo raifed above the furface of the water which before covered it.

This is no new opinion; but this author has fet it in a new and much ftronger light than it ever had appeared in before, by the inftances and examples he has brought in proof of it. Some have been fond of believing that the bodies we call *marine remains*, were never indeed any parts of living animals, but that they are mere *lufus naturæ* formed in the places where they are found; but Fabius Columna proved this to be an error, fhewing that the fhark's teeth, or gloffopetræ of the ifland of Malta, when calcined by a ftrong fire, yielded afhes, the fame with thofe from animal bodies, and by no means of the fame nature with thofe produced from calcined ftones.

That changes of parts of the bottom of the fea into dry land, have often been made, is proved not only from the late known inftances, but from the teftimonies of Strabo, Pliny, and other writers of credit: And nothing is more obvious to reafon, than that in the fudden rife of fuch parts of the bottom of the fea, all its contents, all the fhells, and other hard parts of fifhes lying there, would be carried up with it.

As fome mountains and fome iflands muft have certainly been produced in this manner, it is not impoffible but that all of them may have been fo; and there is no more than this required to account clearly and evidently for all the vaft profufion of *marine* bodies at land as we find them, without having recourfe to the improbable means of the univerfal deluge, which for many plain reafons cannot have been the caufe; or to the effects of particular inundations, which muft have been wholly incapable of lodging many of them there. The lodgment of fhells in the folid ftrata of mountains, is better accounted for by this fyftem of Signior Moro than any other: And if it be afked why fome mountains afford them in great plenty, and others not at all, it will not be difficult to anfwer, by obferving, that among the mountains of the more known parts of the world, fome confift of more folid rock, and others of various ftrata of earthy and other matter; that the firft of thefe may be fuppofed primary or natural mountains, and the others fecondary or accidental ones; and that thefe *marine remains* are always wanting in the former, and ufually are found in the latter, which is a fact greatly favourable to this fyftem.

There are many difficulties attending the accounts of all authors of the formation of the earth, and the lodging thefe bodies in it; nor is this laft fyftem without difficulty. The caufes here affigned as to the origin of mountains and iflands, doubtlefs have been fo in regard to fome, but fcarce to all; and the bodies here treated of are fo numerous, in fome particular places, that fcarce any account can folve the difficulty of their being collected together in fo ftrange a manner.

MARINE *Salt*. See the article SALT.

MARINELLA, in botany, a name by which fome authors have called the great *plu*, or garden valerian. *Ger.* Emac. Ind. 2.

MARINER, the fame with feaman or failor. See the article SAILOR, *Cycl.*

MARI-

MARINERS-*Compass*. See the article COMPASS, *Cycl.*

MARIO, in ichthyology, a name given by Pliny, and other of the old Roman authors, to a large fish allied to the accipenser or sturgeon. There seems, from all that they have said of it, great reason to believe that it was the fish we at present call *huso*, or the ichthyocolla fish, from isinglass made of it. Artedi makes this a species of the accipenser or sturgeon, and distinguishes it by the name of the accipenser without tubercles. See the article ACCIPENSER.

MARJORAM, in botany. See the articles MAJORANA and ORIGANUM.

MARIS, in ichthyology, a name given by Charleton and some others, to a fish called, by the generality of both the antient and modern writers, *smaris*, and by some *leucomenides*, from its whitish colour, and its external resemblance to the fish called *mænis* and *mæna*; it is, like that fish, a species of the sparus; and is distinguished by having a black spot on each side, and the tail and belly fins red.

MARISCA, a word used by chirurgical writers to express an excrescence about the anus.

MARITACACA, in zoology, the name of a very remarkable American animal, more usually known by the name of the opossum. See the article OPOSSUM.

MARITUS, in the chemical jargon, a word used to express the sulphur of metals. The writers on the subject of the philosophers stone usually express themselves in this enigmatical manner, calling sulphur the husband, and mercury the wife in all metals; which, as they are more or less perfectly combined, make the metal more or less pure, and approaching to perfection.

MARK, (*Cycl.*) at sea, the same with *land-mark*. See the article LAND-*Mark*.

MARK, in the manege. A horse *marks*, that is, he shews his age by a black spot, called the bud or eye of a bean, which appears when he is five and an half, in the cavity of the corner teeth, and is gone when the horse is eight years old. After that age he ceases to *mark*, and is said to have razed. See the article EYE *of a Bean*.

False-MARKED is the same with *counter-marked*.

MARK, among bowlers. See the article BOWLING.

MARLE (*Cycl.*)—The *Marles* in the northern parts of England contain sand, and run into a sort of loam: Those in Sussex are more like fullers earth, and therefore are by much the fattest and richest.

Marle, in general, is much of the nature of chalk, and the potters find, that when either chalk or *Marle* happen to be mixed with their clay, they will burn with the rest of the substance, and the vessels will seem very sound; but as soon as any water is put in them, they will run, the chalk or *Marle* having been burnt into a sort of lime, and flaking like common lime with the water.

The *Marles* that are so sandy, that they can scarce hold together, are a very good manure for cold clay lands, and are an objection to the general rule, that *Marle* is not to be used to clay. *Marle*, in general, suits best with hot lands, for it is apt to bind and sadden the tough clays; but as there are no rules without their exceptions, where *Marle* is not laid too thick, and is not of too binding a kind, it will often very much improve pasture grounds, though they are upon a clayey soil.

Cowshut or stone *Marle* is, in most countries, found under clay, or low black land, eight or ten foot deep; clay and steel *Marle* sometimes under sandy land: In clayey ground it seldom lies more than three foot deep; but in sandy ones it is often much deeper. The Sussex *Marle* commonly shews itself pretty low among the broken strata of hanging grounds.

For the digging of *Marle* they commonly use pick-axes, shovels, spades, and wheel-barrows; and where the pit is broad, that they can make an easy ascent, small carts of four foot ten inches long, and two foot three inches wide, and about fourteen inches deep, made so that a load is very easily shot out of them.

Marle is supposed to be fruitful from its salt and oily quality: The salt it is supposed to contract from the air, and therefore many are of opinion, that the longer it is exposed to the air before it is used, the better. They lay it upon the grass ground, in some places, three or four years before they plow it up; and when they cover the arable lands with *Marle*, they will not plow, in many places, to more than an inch deep, that they may not bury it. Markham, indeed, is of a contrary opinion, and would have it buried deep, that the sun may not draw out its virtue. The *Marles* of different places are in themselves so different, that both these opinions seem right in part; the *Marles* of Sussex being found to succeed best where buried deep, as soon as taken from the pit; and those of the north of England seldom doing much good to the lands, unless they are exposed a long time first.

The experience of the farmers in different places has shewn also, that different times are to be observed for the laying it on, according to its nature and that of the land to be improved by it. In Sussex they always lay on the *Marle* in the beginning of winter; and in Staffordshire in May and June. Good *Marle* will flake like lime with the sun's heat in a hot day, especially if there has happened any rain. Some farmers harrow in the *Marle*, just before they plow the land, which is a very good way to mix it perfectly. Cole seed, clover, and all kinds of hay plants, grow well upon marled lands. Lands seated on *Marle* are usually very rich, tho' in their own nature cold and heavy. The deeper these lands are turned up in plowing, the better crops they will always yield. *Mortimer's* Husbandry, p. 95.

It is a very material circumstance in the marling of land, to find out how much the land requires of this manure; and till experience has thoroughly shewn this, it is better to err in laying on too little, than too much; because the latter is a fault not to be remedied. It is to be observed also, that *Marle* never makes so great an improvement on land the first year, as it does afterwards.

In Staffordshire they lay two hundred load of *Marle* upon an acre of land of the common kind; but where the soil is black, loose, and sandy, or full of worms, they will lay on three or four hundred load to an acre; it being a rule with them, that this sort of soil cannot be marled too much. If the mould be thin, the less *Marle* does; if deep, it must have the more.

'Tis best sowing of marled lands under furrow; because if these lands are well husbanded, they will be very mellow and hollow, which will occasion the earth's sinking from the roots of the corn, if it stand too high. If *Marle* saddens land, or makes it stiff or binding, it must be well dunged, and laid down for grass. In Staffordshire, after their land is marled, their way is to take the crops following. After the first crop of wheat is off, they plow in the wheat stubble in December, and if the weather proves frosty, to mellow it, they do not plow it again till April. They then sow it with barley, allowing three bushels of seed to an acre. The common produce of this is thirty bushels. After this they sow pease, for which they plow only once in the February following, allowing only three bushels of seed to an acre, as in the barley. Next after this, if they intend six crops, they sow wheat again upon the pease crop; the fifth crop is barley again; and the sixth year's crop is red oats. Some sow two or three crops more, when the ground has been well marled, but that is much better let alone.

In digging for the *Marle* they use in manuring their lands in Ireland, they meet with fossile horns, and other curious fossils. The *Marle* always lies in the bottoms of low bogs. It is never met with in any other places, and is found by boring with augurs made for that purpose. It usually lies at five, seven, or nine foot depth. The obtaining it in many places is attended with very considerable expences, in draining off the water. The manner of digging it is this: They employ six able labourers, and a supernumerary; and these cut up a hole of twelve foot square, which is supposed a pit that this number of men can manage in one day. Two men dig, two throw it up, and two throw it by, and the supernumerary man supplies defects on all occasions. For the first three foot they dig through a fuzzy earth, fit for making of turf or fuel. Under this lies a stratum of gravel, of about half a foot. Under this often, for three foot more, there is a more kindly moss, which would make better fuel. This lower stratum of turf is always full of fossile wood, which is usually so soft, that the spade cuts as easily through it, as through the earth it lies in. Under this, for about three inches, is found a series of leaves, principally of the oak; these appear very fair to the eye, but fall to pieces on touching; and this stratum is sometimes interrupted with vast heaps of seed, which seem to be broom or furz-seed. In some places there appear berries of different kinds; and in others, several species of sea plants, all lying in the same confused manner as the oak leaves. Under this vegetable stratum, there lies one of blue clay, half a foot thick, and usually full of sea shells. This blue clay is not so tough as common clay, but is thrown carefully up, and used as *Marle* in some places. Under this always appears the right *Marle*; the stratum of this is usually from two to four foot thick, and sometimes much more. Phil. Transf. N°. 394. p. 122.

This *Marle* looks like buried lime, and is full of shells; which are usually of a small size, and of the perwinckle kind; but there are several other sorts, at times, found among them. Among this *Marle*, and often at the very bottom of it, are found great numbers of very large horns of the deer kind, which are vulgarly called elks horns. These, where they join to the head, are thick and round; and at that joining there grows out a branch, which is about a foot long, and seems to have hung just over the creature's eyes; it grows still round for about a foot above this, and then spreads broad, and terminates in branches long and round, turning with a small hind. The labourers are obliged to work in a hurry in all these pits, so that they seldom bring them out whole. There are also, at times, found the leg bones, and other parts of the skeletons of the same beasts; but this more rarely, only a few together, and but in few places.

MARLE, in medicine, is esteemed an astringent, and given as such in diarrhœas, dysenteries, and hæmorrhages; the red kind is preferred for the last intention, though the difference is hardly worth regarding. The Germans give it also in fevers, in convulsions, and particularly in epileptic cases; also in internal bruises.

Dice MARLE, in huſbandry, a name given by the people of Staffordſhire to a reddiſh *Marle*, that breaks into ſmall ſquare pieces like dice, or elſe into thin flakes, in the manner of lead ore, and looks ſmooth on the ſurface. This is a good manure, and the way of judging which of it is beſt, is to expoſe it to the air in rainy weather, or to put it in water. That which moulders ſooneſt to powder in the air, and breaks quickeſt in the water, is ſure to be the beſt, and proves very beneficial to land.

MARLINE, aboard a ſhip, is a ſmall line made of hemp untwiſted, that it may be the more gentle and pliable: Its uſe is to ſeize the ends of ropes from fareing out. They uſe it alſo to ſeize the ſtraps at the arſe (as they call it) or lower end of the block.

MARLING *a Sail*, is when being ſo ript out of the bolt rope, that it cannot be ſewed in again, the ſail is faſtened by a *Marline*, put through the eye-let holes, made in it for that purpoſe, unto the bolt rope.

MARMARYGÆ, a word uſed by the old writers in medicine to expreſs ſparks of fire, or the appearance of ſuch flaſhing before the eyes in ſome diſorders.

MARMORA, *Marbles*, in natural hiſtory. See the article MARBLE.

MARMORARIA, in botany, a name given by ſome authors to the *brancha urſina*,

MARMORATA *Aurium*, a term uſed by ſome authors to expreſs ear-wax.

MARMORELLA, in botany, a name by which ſome authors have called agrimony. *Ger.* Emac. Ind. 2.

MARMOREUS *Tartarus*, a word uſed by ſome authors to expreſs the hardeſt kind of the calculus, or ſtone in the human bladder. See the article STONE.

MARMOTTE, *Marmotta*, the mountain rat, a creature very common in many parts of Europe, and frequently carried about as a ſhew by the poor Savoyards. It is of the ſize of a leveret, or between that of the hare and the rabbit; and is larger bodied than a cat, but much ſhorter legged. Its whole figure and appearance are like the common rat, whence it has its name. Its furr is much harder or harſher than that of the rabbit, and its colour a reddiſh tawney, ſometimes lighter, ſometimes darker; the end of its tail is back. Its eyes are large and prominent, and its ears ſhort, and ſeeming as if cut off. It has two large teeth at the front of each jaw, as the ſquirrel, and other creatures of this kind, and theſe are not white, but yellow, as in the beaver. Its noſe and mouth are adorned with a large number of black whiſkers, making a ſort of beard. The tail is about five inches long, and the legs are thick, and theſe and the belly are covered with long hair. Its toes are diſpoſed as in the bear, and its claws are very long and ſtrong, by means of which it digs the earth very readily. It makes great uſe of its hinder legs, and ſometimes walks on them in an erect poſture. Its back always appears very fleſhy and fat, tho' the reſt of the body be ever ſo lean; but this is not real fat, but a proviſion made by nature to guard the animal from cold. *Ray*, Syn. Quad. p. 221.

They will play with one another in the manner of kittens, and make a ſoft and not diſagreeable noiſe on thoſe occaſions; but when they are provoked, or when they are affected, as they always are by a change of weather, they make a very ſhrill and diſagreeable ſqueaking. They feed on vegetables, and are very fond of the roots of ſeveral plants; they are very fond alſo of milk, butter, and cheeſe. They ſit on their buttocks to eat, and uſe their fore-feet as hands to reach their food to their mouths, in the manner of the ſquirrel. They lie hid in the winter in holes which they dig in the earth, and ſleep away a great part of that ſeaſon. They make their holes in a very nice and artful manner, and make themſelves a bed of ſtraw, and other ſoft matters, that they may lie the ſofter and the warmer. It is a creature eaſily bred up tame, and will be perfectly good-humour'd and familiar, but it hates dogs.

Its legs are very robuſt and ſtrong, and it digs extremely quick. It runs but ſlowly on even ground, ſo that a man may overtake it; but if it once gets into the earth, it is ſaid, it will burrow faſter than a man with a ſpade can dig after it to take it.

This animal, in Poland, is ſaid to herd in large communities, and be governed by a regular policy, making war with parties of its own ſpecies from other places, and taking ſpies and ſlaves, and keeping them for the moſt ſervile uſes; particularly in the carrying in their proviſion for the winter, which they lay on the bellies of theſe ſlaves, firſt laying them on their backs, and then drawing them along with the load, in manner of a cart or waggon.

MAROGUS, a word uſed by Paracelſus to expreſs a very powerful narcotic.

MARQUE (*Cycl.*)—*Letters of* MARQUE. See the article PRIZE.

MARRIAGE (*Cycl.*)—The people in Java *marry* and have children at nine or ten years old, and the women leave childbearing before they are thirty; and at Tunquin there are women common to any that will hire them, at eight or nine years of age.

Potter gives a large account of the ſeveral ceremonies obſerved by the Greeks in their *Marriages*. The Spartans were not permitted to *marry* till they arrived at their full ſtrength. The reaſon aſſigned for this cuſtom by Lycurgus, was, that the Spartan children might be ſtrong and vigorous: And the Athenian laws are ſaid to have once ordered, that men ſhould not *marry* till thirty-five years of age. *Potter*, Archæol. Græc. l. 4. c. 11. T. 2. p. 263. ſeq.

Moſt of the Grecian ſtates, eſpecially ſuch as made any figure, required their citizens ſhould match with none but citizens. The uſual ceremonies in promiſing fidelity was kiſſing each other, or giving their right hands, which was a general form of ratifying all agreements. Before the *Marriage* could be ſolemnized, the gods were to be conſulted, and their aſſiſtance implored by prayers and ſacrifices, which were offered to ſome of the deities that ſuperintended theſe affairs, by the parents, or neareſt relations of the perſons to be married. When the victim was opened, the gall was taken out and thrown behind the altar, as being the ſeat of anger and malice, and therefore the averſion of all the deities who had the care of love, as well as thoſe who became their votaries. For the particularities relating to the bride and bridegroom, ſee the articles BRIDE and BRIDEGROOM.

The ceremonies of the Spartan *Marriages* being different from all others, deſerve to be mentioned at length, as related by Plutarch. "When the Spartans had a mind to marry, "their courtſhip was a ſort of rape upon the perſons they had "a fancy for; and thoſe they choſe not tender and half-"children, but in the flower of their age, and full ripe for a "huſband. Matters being agreed between them, the Νυμφευτρία, or woman that contrived and managed the plot, "ſhaved off the bride's hair cloſe to her ſkin, dreſſed her up "in man's cloaths, and left her upon a mattreſs: This "done, the bridegroom entered in his common cloaths, "ſober and compoſed, as having ſupped at his ordinary in "the common hall, and ſtole as privately as he could into "the room where the bride lay, untied her virgin girdle, and "took her into his embraces. Having ſtayed a ſhort time "with her, he returned to his comrades, with whom "he continued to ſpend his life, remaining with them "as well by night as by day, unleſs when he ſtole a ſhort "viſit to his bride; and that could not be done without a "great deal of circumſpection, and fear of being diſcovered: "Nor was ſhe wanting (as may be ſuppoſed) on her part, to "uſe her wit in watching the moſt favourable opportuni-"ties for their meeting, and making appointments when "company was out of the way. In this manner they lived "a long time, inſomuch that they frequently had children by "their wives before they ſaw their faces by day-light. The "interview being thus difficult and rare, ſerved not only for "a continual exerciſe of their temperance, and furthered "very much the ends and intentions of *Marriage*; but was "a means to keep their paſſion ſtill alive, which flags and "decays, and dies at laſt by too eaſy acceſs, and long conti-"nuance with the beloved object." *Potter*, Archæol. loc. cit. p. 295. ſeq.

According to Mr. Kerſſeboom's obſervations, there are about 325 children born from 100 *Marriages*. See Phil. Tranſ. N°. 468. Sect. 3.

Mr. Kerſſeboom, from his obſervations, eſtimates the duration of *Marriages*, one with another, as in the following table.

Thoſe whoſe ages, taken together, make

40	live together between	24 and	25 years.
50		22	23
60		23	21
70		19	20
80		17	18
90		14	15
100		12	13

Phil. Tranſ. N°. 468. Sect. 3. p. 319.

MARROW (*Cycl.*)—The greateſt part of the bones contain, in their large cavities or cells, this unctuous ſoft ſubſtance, which is more ſolid in ſome, and more ſoft in others. This, while it lies in the cavities of the large bones, is more particularly called *Marrow*; when diſperſed in the ſmall cellulous cavities, it is commonly called the medullary juice. The *Marrow* of the large hollow bones is a maſs compoſed of an infinity of ſmall veſicles, or membranous cells, joined together, and communicating with each other, furniſhed with blood-veſſels and nerves, and filled with a fine ſweet oily matter. All theſe cells are ſurrounded by a fine membrane, which, like an internal perioſteum, ſticks cloſe to the inner ſurface of the bone, by means of an infinite number of capillary veſſels, and of ſeveral other kinds of very ſmall filaments. The reticular ſubſtance of the bones runs through this medullary maſs, and, as it were, interlards it, and by this means ſuſtains it in the middle of the great cavities. The *Marrow* of the cellulous or cavernous ſubſtance of the bones, is divided by ſmall bony ſepta or plates, and by filaments of the reticular ſubſtance of the bones into a vaſt number of veſicles or membranous cells, which line the bony cells, and communicate with each other.

This cellular *Marrow* in the cavernous texture of ſome bones, differs from that in the great cavities of others both in colour and conſiſtence. It is liquid, and of a red colour throughout; whereas

whereas the other is more folid, and is only red on its furface. This difference is owing to the blood-veffels which run thro' each membranous cell, whereas the *Marrow* in the great cavities feems to be furnifhed with them in the common membrane only. Many of thofe medullary cells are likewife divided by the bony filaments of the cavernous fubftance; and thefe fmall filaments, as well as thofe of the reticular texture, are covered by portions of the medullary membrane, as by a periofteum.

The medullary membranes may be feparated from the liquor which they contain, by fteeping the whole mafs in very hot water, and afterwards compreffing it by gentle degrees. But it is to both thefe fubftances, taken together, that the anatomifts give the common name of *Marrow*, not to either of them taken fingly. The medullary membrane is very fenfible, but not the juice, which is neceffary to be obferved, to underftand properly what is meant by the fenfibility of the *Marrow*. The *Marrow*, by its liquid and unctuous part, renders the bones in fome meafure pliable, and lefs brittle, as it continually pervades their fubftance in fmall degrees: This continues to old age, and then the bones, being deprived of their *Marrow*, become very brittle.

In the bones of the offa innominata, there are no internal large cavities; but their fubftance being cellulous or cavernous, they contain no medullary mafs, but their cells are all moiftened with a medullary juice, which diftils inceffantly through the membrane with which they are lined. In the os femoris the *marrow* lies in a large mafs, in the middle cavity of the bone, and in fmall diftinct clufters in the cells of each extremity. The firft is penetrated at different diftances by the bony filaments, and is thereby fuftained in all violent motions and fhocks, as running, leaping, and the like. In the bones of the leg the difpofition is exactly the fame; and in the bones of the foot, the *Marrow* is fuitable to their internal ftructure, and is lodged in moleculæ, in the cavernous portions, and in maffes in thofe which have cavities to receive them. Thus the *Marrow* of all the tarfal bones is difperfed in moleculæ, becaufe their internal ftructure is fpongy. In the metatarfal bones, and firft phalanges of the toes, it is difpofed in the fame manner as in the tibia and fibula, that is, it lies in moleculæ in the extremities, and in their middles in greater or leffer maffes, according to the fizes of the cavities. In the other phalanges, which are entirely fpongy, it is accordingly difpofed in moleculæ. In the vertebræ, fternum, and ribs, the internal ftructure of all which is cellular and fpongy, the *Marrow* is contained only in fmall feparate portions, and is no other than a red medullary juice. The bones of the head alfo being in like manner cellular in their internal ftructure, contain alfo their *Marrow*, in like manner, in diftinct portions, and lying in membranous cells in the diploe. *Winflow*'s Anatomy, p. 118, 136, 150, 152.

The tranfpiration of the unctuous matter of the *Marrow* is not confined to the time of the animal's life, it is even carried on in the dead carcafs, and is one great obftacle to the whitening and cleaning the bones in a fkeleton; for if there be not an opening made at one end of a bone, and the *Marrow* wafhed out of the whole bone at this aperture, by means of proper liquors injected with a fyringe, the bone, though made ever fo white at firft, will certainly turn yellow afterwards, by this tranfpiration of the *Marrow* contained within it, which certainly happens on the leaft heat of the weather, or otherwife. For this reafon it is alfo, that the workmen who ufe bones always cut them longitudinally in two, and take out all the *Marrow*, and even all the fpongy fubftance of the bone, which might be fuppofed to contain it, otherwife they know that the heat of any one's hand will turn their works yellow, tho' ever fo white when firft made. It is to be obferved, that there are in the hollow bones feveral fmall apertures thro' which there pafs blood-veffels, which go from the membrane enclofing the *Marrow*; whence it appears that the bones are indeed nourifhed from within as well as from without, though that be not by the *Marrow*, but by the blood-veffels only: Thus the two tables of the fkull are evidently nourifhed; the external one by the veffels of the pericranium, and the interior by the branches of thofe veffels which are fpread along the *dura mater*.

It has been fuppofed that the quantity of *Marrow* increafed in the bones according the increafe of the moon; but this has been found a wholly erroneous opinion, the increafe of the *Marrow* in all the bones depending on the quantity of nourifhment, and the ftate of reft which the creature is allowed.

The fenfation of the *Marrow* has been a point very varioufly fpoken of. When a limb has been taken off, and the *Marrow* is left bare, if any thing touch it roughly, the patient feels an exquifite pain. Some had fuppofed that this fenfation might rather arife from the membranes, than from the fubftance of the *Marrow*: This, however, was put beyond all doubt by a curious, tho' very cruel operation, performed before the Paris academy. A living animal had its leg taken off before the academy, and the end of the bone left very bare, the membranes were all carefully removed, to the exquifite pain and torture of the creature; and when the pain of this was over, the end of a ftyle was plunged into the *Marrow*, without touching any other part whatever, and the creature, on this, expreffed as violent a fenfation of pain as from any of the former operations: This was repeated feveral times, and always with the fame event; fo that it is very evident that the *Marrow* is, in its natural ftate, highly fenfible of pain; and how much more may it be fo in diftempered bodies! Mem. Acad. Par. 1700.

The antients fuppofed that the *Marrow* ferved for the nourifhment of the bones; and their reafons for believing it were, that they faw no blood-veffels enter the fubftance of the bones, by which they could be nourifhed, all the veffels of that kind, which they could difcover, going directly into their cavities, where the blood they contained feemed to undergo a fort of concoction, which converted it into *Marrow*, and by that means rendered it fit nutriment for the bones; and they obferved, in proof of this, that the longer any bone was, and the more violent ufes it was intended for, the larger was its cavity for the containing this nutritious matter.

Thefe reafons, though they carry a great fhew of probability, yet are eafily refuted by accurate obfervation. We fee, in young fubjects, a vaft number of blood-veffels diftributed thro' the fubftance of the bones, the texture of which, at that time, is lax and fpongy. It is alfo to be obferved, that there are many bones in the human body, as well as in brutes, which, according to this fyftem, could not be nourifhed at all, fince they contain no *Marrow*. Of this kind alfo are the horns of deer, and many other creatures, which, tho' they contain no *Marrow*, yet grow very vigoroufly. There are alfo other bones which are hollow, yet are only cloathed with a glandulous membrane; fuch are the cavities between feveral parts of the two tables of the fkull: And in the elephant, the foliaceous bones, which are in the place of the diploe, contain no *Marrow*, and are only covered with a membrane, which has feveral blood-veffels fcattered through it. The hollows of thofe bony fubftances alfo which compofe the claws of crabs, lobfters, and the like, contain no *Marrow*, but only the mufcles, whofe office it is to move thofe parts; and yet all thefe grow, and are nourifhed, as well as thofe bones which contain ever fo much *Marrow* in their cavities. In fine, it may be well concluded, that it is not for the fake of containing *Marrow*, that the bones are made hollow, but merely that they may be lighter, and more fit for motion. Mem. Acad. Par. 1700.

Obfervation gives abundant proofs, that a great quantity of the *Marrow* continually tranfpires through the folid fubftance of the bones, and in this action it is of great ufe, though not in the nourifhing, yet in the preferving the bones, its oily and unctuous matter foftening the rigid fibres of which the bone is compofed, and rendering them more fupple, foft, and flexile, and confequently the whole bone much lefs liable to break.

MARRUBIASTRUM, baftard *Horehound*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is of the labiated kind. The upper lip is hollowed in the manner of a fpoon, and the lower is lightly divided into three fegments. The piftil arifes from the cup, and is fixed, in the manner of a nail, into the hinder part of the flower. It is furrounded alfo by four embryos, which afterwards become as many feeds of a roundifh fhape, ripening in a fort of open cafe, which was the cup of the flower. There is, befide thefe marks, alfo a peculiar face in the flower of this plant, by which it is, at fight, diftinguifhed from the galeopfis.

The fpecies of *Marrubiaftrum*, enumerated by Mr. Tournefort, are thefe: 1. The common *Marrubiaftrum*, called by fome, the Germander-leav'd Ironwort, or Sideritis. 2. The marfh ftinking *Marrubiaftrum*. 3. The white-flowered fideritis-leav'd *Marrubiaftrum*, with prickly flower-cups. 4. The fideritis-leav'd *Marrubiaftrum*, with prickly cups, and yellow flowers, with edges of a blackifh purple. 5. The motherwort-leav'd *Marrubiaftrum*. 6. The American *Marrubiaftrum*, with the flowers collected into heads, and with a fweet fmell like that of baum. *Tourn.* Inft. p. 190.

MARRUBIUM, *Horehound*, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is of the labiated kind; the upper lip ftands erect, and is divided into two horns; the lower is divided into three fegments. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower. It is furrounded by four embryos, which afterwards become four oblong feeds, and are contained in a fort of open capfule, which was before the cup of the flower. *Tourn.* Inft. p. 192.

The fpecies of *Horehound*, enumerated by authors, are thefe: 1. The common white *Horehound*. 2. The hairy white *Horehound*. 3. The broad and roundifh-leav'd exotic *Horehound*. 4. The fhort-leav'd white *Horehound*. 5. The narrow-leav'd white *Horehound*. 6. The procumbent Spanifh *Horehound*, with ftellated and prickly flower-cups. 7. The procumbent Spanifh *Horehound*, with filky and filvery leaves. 8. The ftinking *Horehound*, as we call it, is the *ballote*, a different genus of plants; and the water *Horehound*, which is the *lycopus*, is alfo to be feen under its proper head.

Marrubium is faid to be an attenuant and refolvent; it is famous for the relief it gives in moift afthmas, and in all dif-

cafes of the breaft and lungs, in which a thick and vifcous matter is the caufe. It is alfo capable of doing great good in many chronic complaints, where the caufe is of the fame kind. At prefent, however, it is very little ufed in the fhops. There ufed to be a compound fyrup of it, which is now out of ufe. See the article ASTHMA.

MARSHMALLOW, *Althæa*, in botany, the name of a genus of plants, the characters of which are the fame with thofe of the mallow, excepting that this has hairy or hoary leaves. See the article MALLOW.

The fpecies of *Althæa* or *Marfhmallow*, enumerated by Mr. Tournefort, are thefe: 1. The common *Marfhmallow*, the *Althæa* of all the old medicinal writers. 2. The angular-leav'd *Marfhmallow*. 3. The rounder-leav'd *Marfhmallow*. 4. The fhort blunt-leav'd *Marfhmallow*. 5. The round-leav'd hoary fhrubby *Marfhmallow*. 6. The great-flowered *Marfhmallow*. 7. The fharp-pointed-leav'd tree *Marfhmallow*, with fmaller flowers. 8. The round-leav'd Spanifh tree *Marfhmallow*. 9. The Portugal tree *Marfhmallow*, with round undulated leaves. 10. The larger-leav'd lefs hairy Portugal tree *Marfhmallow*. 11. The Venetian fea tree *Marfhmallow*, the common *malva arborea* of authors. 12. The French tree fea *Marfhmallow*. And 13. The Spanifh *Marfhmallow*, with undulated leaves. *Tourn.* Inft. p. 97.

The parts of *Althæa*, ufed in medicine, are the leaves and roots. The leaves, by decoction, afford a foft mucilaginous fubftance, good in all complaints arifing from acrimony; of great fervice in dyfenteries, *&c.* where the *mucus* of the inteftines is raked off, and in many kinds of colics. It is alfo found of ufe in obftructions of the urinary paffages, ftranguries, heat of urine, *&c.* and is, by fome, held a great fecret for the cure of a *gonorrhœa*. Ray and others alfo fpeak of it as a pectoral; of ufe in coughs, and alfo pleurifies.

Marfhmallow root is a very valuable medicine. It is emollient and diuretic, and gives great relief in diforders of the kidneys and bladder, whether arifing from acrimony of the urine or gravel. It is good alfo in all diforders of the breaft and lungs, arifing from a thin acrimonious phlegm. In both which cafes, a decoction of the frefh root is the beft way of giving it. In diarrhœas and dyfenteries, a ftrong decoction of *Marfhmallow*-root, given clyfterwife, is alfo of great ufe. Externally, in form of a cataplafm, it is excellent for foftening and maturating hard tumours.

The fyrup of *Marfhmallows*, is lefs efficacious than the decoction; on account of the fugar in the former, which makes an improper mixture with medicines of the mucilaginous kind.

Ointment of *Marfhmallows*, called *Unguentum Dialthææ*, is applied to tumours and inflammations, as an emollient and fuppurative; which qualities it derives from the mucilage of the plant, being boiled a long time with the oil, before any of the other ingredients are mixed.

The *Emplaftrum Diachylon* receives much of its virtue from the fame plant.

The *Althæa* of the antients was plainly a different plant from that which we call by that name. Our *Althæa*, or *Marfhmallow*, is a very common plant, and grows in watery places, principally near the fea; but the *Althæa* of the antients was a fcarce herb, and grew in the barren defarts of Arabia, Afia, and the ifland of Sicily. Theophraftus fays it was found in no other place. The Arcadians called it, the *wild Mallow*; and only the people who ufed it in medicine called it *Althæa*. Theophraftus gives us this account of it, and adds, that its flowers are yellow; a circumftance in which it wholly differs from any of the accounts of later authors of the *Marfhmallow*. and from the plant itfelf, which we know by this name, its flowers being white. Diofcorides gives the fame account of the colour of the flower, and adds, that it was like a rofe in fhape: And other authors fay, that its flower was like a rofe, but do not mention whether that likenefs confifted in the fhape or colour. Others have recorded the liknefs of a rofe, and applied it to the colour of this flower, calling it a little flower, of the pale colour of a rofe. Thefe authors may, probably, have adapted the defcriptions of the antients, in the cafe of the rofe-like flower, to the common *Marfhmallow* of our times; but the defcriptions, as we find them in the antients, feem rather to refer us to the *Abutilon*, or yellow *Mallow* kind, than to our own *Althæa*. *Theophraft.* l. 9. c. 15. See the article ABUTILON.

MARSHY *Lands*, a name given by our farmers to a fort of pafture land, or grazing ground, which lies near the fea, rivers, or fens.

As to lands lying near rivers, the great improvement of them is their being overflowed, which brings the foil of the uplands upon them, fo that they need no other mending, though kept conftantly mowed. The great inconveniency of thefe lands, is their being fubject to floods, which high hills near the fides of rivers, and the long courfe of them, befpeak to be frequent. And though the richeft land generally lies near fuch rivers, yet there is the greateft danger of the crops being fpoiled, efpecially when they are not enclofed; and therefore cannot be fed with cattle. This, when feeding bears any thing of a price, would be the very beft way of managing thefe uncertain lands; and enclofing them would be highly beneficial, on this account. *Mortimer*'s Hufbandry.

The *Marfh*-lands in Lincolnfhire, and many other parts of England, produce a fort of grafs, which feeds fheep in a better manner than that of almoft any other land, in regard to their fize, and the quantity of wool. The fheep about Grimfby, and fome other places in this county, produce fuch lufty wool, or, as they call it, wool of fo large a ftaple, that three or four fleeces ufually make a tod of twenty-eight pound weight. Several hundred loads of this wool are yearly carried from thefe places to Norfolk, Suffolk, and other parts of the kingdom, for the cloth manufacturers. They fend this in large packs, which they call pockets, each containing about five and twenty hundred weight. Phil. Tranf. N°. 223.

When *Marfh*-lands lie flat, it is neceffary for the owner to keep all the water he can from them. The fea water, in particular, is to be kept from them as much as poffible; and this is ufually done at a very great expence, by high banks and walls.

Two things greatly wanting in thefe lands in general, are good fhelter for the cattle, and frefh water. The careful farmer may, however, in a great meafure, obviate thefe, by digging, in proper places, large ponds to receive the rain water, and by planting trees and hedges in certain places toward the fea, where they may not only afford fhelter to the cattle, but keep off the fea breezes, which often will cut off the tops of all the grafs in thefe places, and make it look as if it had been mowed.

Thefe lands fatten cattle the fooneft of any, and they preferve fheep from the rot. It would be a great advantage to them, if there were raifed, in the middle of every large *Marfh*, banks of earth in a crofs, or in the form of two femicircles, and thefe planted with trees; thefe would ferve as a fhelter for cattle, let the wind blow from what quarter it would, and would foon repay the expence of making. *Mortimer*'s Hufbandry.

There are, in different parts of England, very large quantities of land upon the fea coafts that would be worth taking in, though no one has yet thought of doing it. The coafts about Bofton, Spalding, and many other parts of Lincolnfhire, give frequent inftances of this, where the fea falls from the land, fo that on the outfide of the fea walls, on the owfe, where every tide the falt water comes, there grows a great deal of good grafs, and the owfe is firm to ride upon when the water is upon it.

This owfe, when taken in, hardly finks any thing at all, and they dig the walls from the outfide of it, all the earth they are made of being taken from thence, and the fea, in a few tides, filling it up again: And though the fea, at high water, comes only to the foot of the bank, yet once in a year or two fome extraordinary tides go over the banks, though they are ten foot high. Thefe banks are fifty foot broad at the bottom, and three foot at the top; and the common price of making them is twenty-fix fhillings a pole, the earth being all carried in wheel-barrows, and the face toward the fea, where the greateft flope is, being turfed. *Mortimer*'s Hufbandry.

MARSILÆA, in botany, the name by which Linnæus has called the pepper-grafs, called by the Englifh botanifts, *gramen piperinum*; by Vaillant and others, *pilularia*; and *falvinia* by Micheli. The characters are thefe: It is one of the *cryptogamia*, or thofe plants which perform their fructification in fecret. The male flowers are very numerous, and ftand on the leaves without any pedicles. Thefe have no cup, but are each only a fingle filament, or receptacle, of a hemifpherico-convex form, with four pointed antheræ, which are long, erect, and fpirally twifted. The female part of the fructification has no cup or petals, but confifts of a round quadrilocular fruit, which contains a vaft number of roundifh feeds. *Linnæi* Gen. Plant. p. 508. *Micheli*, p. 58. *Vaill.* Bot. Par. 15. 6. See the article PILULARIA.

MARSUIN, in zoology, a name by which many have called the *phocæna* or *porpeffe*, a fifh too often confounded with the dolphin. *Willughby* Hift. Pifc. p. 31. See the articles DELPHINUS and PHOCÆNA.

MARSUPIALE, in natural hiftory, a name given by Tyfon to the creature commonly called, the *poffum*, or *opoffum*. The peculiar diftinction of this creature from all others, is its having a pouch, or *marfupium*, under its belly, into which it receives its young in time of danger. This has given occafion to its name *Marfupiale*, but it is more generally called *opoffum*. See the article OPOSSUM.

MARSUPIALIS *Mufculus*, in anatomy, a name given by Cowper, and fome others, to a mufcle of the thigh, called alfo by fome, *burfalis*. It is that mufcle, called by Albinus, Winflow, and the generality of modern authors, *obturator internus*.

MARSUPIUM *Carneum*, in anatomy, a name given by Spigelius, Cowper, and fome other authors, to certain mufcles of the thigh, called by the French writers, *les petits jumeaux*, and by Albinus, *gemini*. Vefalius does not efteem them feparate mufcles, but calls them only *carneæ portiones decimo femur moventium mufculo attenfæ*, flefhy portions affixed to the tenth mufcle of the thigh.

Riolan, who calls the *pyriformis*, or pyramidal mufcle of the thigh, the *quadrigeminus*, or *quadrigeminus prior*, calls thefe the *quadrigemini fecundi & tertii*. They are fometimes diftinct, fometimes they grow together.

MARTEAU, the name given by French naturalifts to a peculiar fpecies of oyfter, called alfo *malleum* by others. It is one

of

of the most curious shells in the world. Its figure is that of a hammer, with a very long head, or rather of a pick-ax. It has a body of moderate thickness, and two long arms. It is of a brownish colour, with a beautiful tinge of a violet blue. Notwithstanding the strange shape of these shells, they close very exactly. See the article OSTREA.

MARTIALES *Flores*. See the article FLORES *Martiales*.

MARTES, the *Martin*, or *Martlet*, in the history of quadrupeds, the name of a creature of the weasel kind, called also by some *Fogua*. There are two species of this creature, the one called the *Martes Abietum*, or fir *Martin*, the other the *Martes Fagorum*, or beech *Martin*. The beech *Martin* is distinguished from the other by having a larger and blacker tail, and being all over of a darker colour, and by being white on the throat, whereas the others are yellow; but the species are scarce kept up distinct, the creatures mixing with one another in the breed. When distinct, the beech *Martin* is found to be a much tamer creature than the other, and may be kept about houses like a cat; and often lives of its own accord about houses, and among old walls. Their skins make a valuable furr; and that of the fir *Martin*, or yellow kind, is much the most valuable. *Ray*'s Syn. Quad.

The *Martin* is of the size of a cat, but longer bodied; its legs also are shorter, and its claws less sharp, and shorter. Its whole body is covered with hair of a yellowish black, except only the throat, which, in the beech *Martin*, or tame kind, is white; and in the wild kind, or fir *Martin*, yellow. Its teeth are sharp and strong, and the dog-teeth, in particular, stand out a great way.

Gesner once kept one of the beech *Martins* tame like a dog, which would go out with him, and run about to the neighbours houses, always returning carefully home again, and would play like a cat, lying on its back, and biting in jest, but never hurting any thing. *Gesner*, de Quad.

This creature leaves so strong a scent, that the hounds, when out in a morning, will often take it, and make a noble cry. The chace, in this case, is very good while it lasts, but it is very perplexed; for the creature is not able to run long; and when she is tired, she gets up into a tree; the hounds often lose her on this occasion; but if she is spied up in the tree, she is to be hunted down with sticks, &c. When killed, the hounds are not to be suffered to eat her flesh, for it is unwholesome. See Tab. of Quadrupeds, N°. 22.

MARTICHORA, in natural history, the name given by the antient Greeks to the animal which we call the *Mantichora* or *Man-tyger*. See the article MANTICHORA.

MARTIN, in zoology. See the article MARTES, supra.

MARTINAZZO, in zoology, the name of a species of water fowl, of the larus or gull kind, and called by the Dutch, the burgomaster of Greenland; by the Cornish people, the *waggell*, or the *great grey gull*. It is a large bird, usually weighing a pound and half. It is all over of a mottled colour of brown, grey, and white; but is much darker on the back than on the belly. The back and wing feathers are all brown in the middle, and grey at the edges; but those of the rump are mostly white. They say that this gull will follow the smaller lari, and persecute and terrify them till they void their food in excrements half digested, which he afterwards picks up, esteeming it better than fresh food. *Ray*'s Ornithology, p. 266.

MARTINO *Pescatore*, in ichthyology, a name given by Salvian, and some others, to the *Rana Piscatrix* of authors; the *lophius* of Artedi. See the article LOPHIUS.

MARTIOBARBULI, among the Romans, a designation given to soldiers, who carried leaden balls to annoy the enemy with. *Pitisc*. Lex. Ant. in voc.

MARTIORA, or MARTICORA, in natural history, the name which the antient Greeks gave to the animal which the Romans called *Mantichora*, and we, from a corruption of that word, the *man-tyger*. See the article MANTICHORA.

MARTIS *Arbor*. Beside the common *Arbor Martis*, which is but a poor resemblance of the *Arbor Dianæ*, Mr. Lemery has found a method of making a saline or vitriolic one, which is of greater beauty than any other metallic vegetation, and which differs from the generality of them, in that it is produced above the surface of the liquor, not under it, and buried in a fluid as they are. Mem. Acad. Par. 1707.

The method by which he first made this beautiful production was this: He dissolved steel filings in spirit of nitre, and adding to the solution oil of tartar *per deliquium*, when the fermentation was over, there arose beautiful vegetations above the surface of the liquor, many of which expressed trees and plants, not only in their leaves and branches, but even in their roots, the small fibres which represent them in this vegetation being truly hollow, and seeming to serve the office of roots in conveying up the fluid matter to the other parts, there to condense into leaves and branches.

In the making the solution of iron for this process, there is always a great quantity of red vapours thrown up out of the mouth of the vessel; if these are saved, by making the solution in a cucurbit, they are found to be a weak spirit of nitre, impregnated with the sulphur of iron; and this spirit serves much better for the making this *Arbor Martis* than the plain spirit. Mr. Lemery observing this, distilled spirit of nitre on purpose for this use, from a solution of a large quantity of iron in the same spirit.

This new spirit evidently contained many of the sulphureous particles of the iron, and produced infinitely more beautiful vegetations than the plain kind. Nor is it wonderful that it should do so, since the success of the process seems wholly to depend on the quantity of the sulphur of iron which is concerned in it. The solution of iron in spirit of nitre, whether the common kind, or this prepared on purpose for this vegetation, is of a reddish colour, and when the oil of tartar is mixed with it, the vegetation is more or less perfect according to the proportions, as will be learned by experiment, and very often the whole liquor, or nearly the whole, raises itself up to the top of the vessel in form of beautiful branches. Mem. Acad. Par. 1707.

The oil of tartar, when first mixed with the solution, causes an effervescence, and when this is over, the liquor becomes quiet and clear again, but is of a deeper red colour than before. Soon after this the vegetations begin to form themselves, by small crystals, which appear upon the surface of the liquor. These are extremely small and slender, and they increase in length continually by the addition of others at their bottoms, thrusting them farther up, till at length they form threads or filaments, which arise out of the surface of the liquor, and thence diverge and divaricate into all the beautiful variety of trees, bushes, and herbs. These nicely adhere to the internal surface of the glass, and, when they have risen to its verge, fall over it, and run down the outside in the same manner, so as beautifully to represent vines, ivy, or other creeping plants running along a wall. Many of the first formed filaments, in this case, encrease greatly in size, often becoming, at length, as thick as a writing quill; and these are always hollow within, and resemble so many pipes. They are so arranged at the bottom of the glass, round the surface of the liquor, as to support the rest of the vegetations. The least heat melts and destroys all these vegetations; barely touching them with the finger being sufficient to resolve them into the liquor from which they arose.

The essential substance of this beautiful vegetation is a mixture of iron with salt petre. The differences in the time and manner of the formation of the branches, does not depend wholly upon the different proportions of the liquors, but frequently on the temperature of the air; and sometimes on the shape and size of the vessels. When the vegetation is first formed, it is usually less beautiful and distinct than afterwards. This is owing to its being too humid, the abundant moisture swelling the parts, and injuring their figure. When it is dried to a certain degree, it appears in all its beauty; and after this it usually soon changes for the worse, the leaves appearing as if faded, and their red colour being changed to a faint orange colour.

The same vegetations which have been once raised, will not, on melting them in water, vegetate again; but only form a number of flat and thin crystals. This is the general event of the operation; yet sometimes, when the solution has been suffered to stand till it acquires a deep red colour, a part of the salts will rise up from the surface, in something like their pristine form; but this is only a small portion of the whole that does it, the greater part remaining at the bottom of the vessel, in form of rigid crystals.

The author of this curious discovery acknowledges that it was owing to accident; for that he had a very different thing in his thoughts, when he mixed the oil of tartar with the solution of iron; but as so beautiful an effect appeared, he was at the pains to vary all the ingredients, in different mixtures afterwards, to try what differences would be produced. He mixed the volatile alkalis instead of the fixed; other acids instead of spirit of nitre, and other metals instead of iron, in the several processes, the events of which were as follow:

Spirit of sal armoniac added to the solution instead of oil of tartar, precipitates a yellow powder to the bottom of the vessel, but does not make the least tendency towards vegetating. All the other acids were tried also in the place of spirit of nitre, and though all of them made the liquor begin to rise sooner than that, yet they only produced a saline crust over the surface, without any tendency to vegetation. Nay, spirit of nitre itself cannot form the vegetations, if impeded by a mixture of any of the other acids. Distilled vinegar, used instead of these acids of the mineral kingdom, produced only a a set of crystals which crossed one another, without any appearance of vegetation. Copper seemed the metal most likely to succeed instead of iron, as being, of all the others, the most sulphureous; but the event, on trial, by no means answered the expectation, and not the least tendency to vegetation was found on treating it in this manner. Copper and iron, mixed together, produced only a low and very poor vegetation, evidently shewing that the copper did nothing but impede the iron from shewing itself in its natural beauty. Quicksilver succeeds no better than copper; there is only formed, by long standing, a thin crust upon the surface of the glass, whence the liquor has evaporated, and the mercury is finally found precipitated to the bottom of the vessel. Bismuth was also tried

tried with the same circumstances, but without success. Mem. Acad. Par. 1707.

MARTIS *Lixivium*. See the article LIXIVIUM *Martis*.

MARTLETT, in zoology, a name used by some for the *Martin*, a creature of the weasel kind. See the article MARTES.

MARTNETS, in a ship, small lines fastened to the leetch of a sail, being reeved through a block on the top-mast head, and coming down by the mast to the deck. Those *Martnets* which belong to the top-sails are fastened after the same way to the heads of the top-gallant masts, but their fall comes down no farther than the top, when it is haled. The word is, *top the Martnets*; *i. e.* hale them up. Their design is, in furling the sail, to bring that part of the leetch which is next the yard-arm close up to the yard, that so the sail may furl up the closer.

MARTYNIA, in botany, the name of a genus of plants, the characters of which are these: The perianthium is composed of one leaf, divided into five segments, which are pointed at the ends, and serrated at the sides; three of these stand erect, the other two are reflex. The flower consists of one petal, and is of the bell-fashioned kind. The tube is large, inflated, and open, and contains a honey juice in its base. The limb is small, and is slightly divided into five segments, the lower of which is larger than the rest, and is more erect and crenated at the edges. The stamina are four capillary and and crooked filaments, one pair of them being bent between the other, and returning back again; and between the upper pair there appears the rudiment, as it were, of another filament, which terminates in a point. The antheræ are connected together, and bend toward each other at the points. The germen of the pistil is oblong, and placed beneath the cup. The style is short and simple. The stigma is flat. The fruit is an oblong, gibbous capsule, of a square figure, each side having two furrows on it. It is pointed at each end, and, when fully ripe, opens at the top into two parts, and is found to enclose four oblong seeds in a sort of square case or nucleus. The bending of the stamina is a very singular thing in this plant; but it does not happen till the apices have burst, and discharged their farina. *Linnæi* Gen. Plant. p. 292. *Martin.* 1. 42. Hort. Malab. 9. 53.

The plant called by Houston *martyniæ species*, is properly another genus, and has been since described by the accurate Linnæus under the name of *craniolaria*. *Houston*, A. A. See the article CRANIOLARIA.

MARTZIAN, in the materia medica, a word formed by the modern Greek writers, to express a sort of sea plant, used in painting, dying, &c.

The word is formed of the Arabian name *margian*, by changing the *g* into *tz*, a very common practice among these writers, and of which we have numerous other instances. It is generally supposed that the *Margian* of the Arabs, and consequently the *Martzian* of the Greeks, is coral. But all accounts of the antients disagree with this, and shew that the plant, meant by these names, is the *fucus thelassius* of the old Greeks, a red kind of sea weed, growing upon the rocks, and used in painting and dying. The antient Arabs all used the word in this sense. But the modern Greeks have been led away by the errors of the successors to the Arabians; so that they use it as a name for coral.

MARU, in botany, a name by which Dodonæus and some others have called the *cerinthe*, or *honey-wort*. Ger. Emac. Ind. 2.

MARUBIUM, *Horehound*, in botany, &c. See the article MARRUBIUM.

MARVELL *of Peru*, a name given to the plant more usually called *jalap*. See the article JALAP.

There are many species of this beautiful plant propagated in flower-gardens. They are all to be raised by sowing their seeds in March, on a moderate hot bed. When they come up, they are to be transplanted to another hot bed, where they are to be set at ten inches distance; and when they are grown to about a foot high, they are to be transplanted into pots filled with light earth, and set in the shade till they have taken root, after which they may remain abroad till October. The stronger kinds should be then removed into the greenhouse, where they must be frequently watered during the winter, and in summer they must be often pruned to keep them in shape.

They flower in June, and continue flowering till the frost prevents them. Some take up the roots when the stalks are dead, and lay them up in sand till spring, when they are planted again in pots, and plunged into a moderate hot bed to facilitate their taking root. And the plants, from the roots of the former year, will always flower much stronger than the seedlings of the same year's growth. *Miller's* Gardener's Dict.

MARUM, the herb *Mastic*, in botany, a name given to one of the species of *thymbra*. See the article THYMBRA.

It is a plant very common with us in the gardens of the curious, and is propagated by planting cuttings in any of the summer months on a bed of fresh light rich earth, where they are to be carefully watered and shaded till they have taken root; after which they may be removed either into pots or borders. But the greatest difficulty attending the keeping this plant, is the preserving it from cats, which will come a great way, and tear them to pieces. It is observed, however, that though these animals never spare a plant that grows single, they will not meddle with it when planted in large clusters, which is indeed the only way to save it. *Miller's* Gardener's Dict.

The common herb *mastic* is a cephalic, and is of service in all disorders of the nerves. It has also an astringency, by means of which it is of service in hæmorrhages of all kinds, particularly in profluvia of the menses.

MARYGOLD, *Caltha*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the radiated kind; its disk is composed of several floscules, and its outer circle of semi-floscules; these are all placed upon the embryo seeds, and contained in a common cup. The The embrios finally become flat, crooked, and marginated capsules, containing a long shaped seed.

The species of *Marygold*, enumerated by Mr. Tournefort, are these: 1. The common *Marygold*, with pale yellow flowers. 2. The common *Marygold*, with deeper yellow flowers. 3. The common *Marygold*, with reddish yellow flowers. 4. The tallest many-flower'd *Marygold*. 5. The common great many flower'd *Marygold*. 6. The great many flower'd *Marygold*, with bright yellow flowers. 7. The great many flower'd *Marygold*, with honey-colour'd flowers. 8. The *Marygold* with bending flowers. 9. The great flower'd proliferous *Marygold*. 10. The great proliferous *Marygold*, with honey-coloured flowers. 11. The proliferous *Marygold*, with smaller flowers. 12. The *Marygold* with variegated flowers. 13. The wild or field *Marygold*. 14. The smallest dwarf *Marygold*. 15. The African *Marygold*, with flowers white within, and of a violet blue on the outside. 16. The wild Portugal *Marygold*. 17. The woolly sea Portugal *Marygold*. *Tourn.* Inst. p. 498.

The flowers of the common *Marygold* are cordial and alexipharmic; they promote sweat, and are good to throw out the small-pox, or any other eruption. They also promote the menses, and are so far aperient, that they are found of service in the jaundice, and in indurations of the spleen. The midwives burn them under women whose labour does not come on properly, and suppose they are of great virtue in promoting the pains. They also distil a water from them, as a remedy for sore eyes; but these last virtues are not so well warranted.

African MARYGOLD. See the article TAGETES.

Corn MARYGOLD. See the article CHRYSANTHEMUM.

Marsh MARYGOLD. See the article POPULAGO.

Zoophyte MARYGOLD, in natural history, the name of a species of sea animal, of a very beautiful kind, and of the nature of those commonly called *Zoophytes*, or plant animals, by the old naturalists. In St. Lucy's parish, in Barbadoes, there is a cave in which is a bason of very clear salt water; and in the midst of this bason lies a stone, which has been for many years found to be the habitation of a great number of animals of this species.

The stone is always covered with water; and from small holes in its sides, in several parts, there appear, at all times of the year, a number of creatures representing the flowers of some of the radiated plants, and particularly of the common *Marygold*: They are yellow, and seem compofed of a very great number of petals. These, in their natural state, are all regularly and beautifully expanded; but as soon as any thing disturbs them, if it be only the motion of a stick that comes within three or four inches of them, they in an instant close all the leaves up together, and the whole body, flower, stalk and all, is retracted back into the hole of the stone; but if the water be left a few minutes undisturbed again, they will appear and expand themselves in the former manner.

When they are nicely observed, there is a yet farther resemblance of a flower in their structure; for there arise from the center of the body certain oblong bodies, which very naturally resemble the stamina arising from the center of a flower; but these have evidently the powers of animal limbs; for they no sooner appear, but they dart themselves about to the verge of the flower in several directions, and are plainly busied in search of prey. They are composed of several joints, and the creature often makes them meet in the manner of a forceps, to lay hold of any thing it pleases. These parts, however, seldom appear thus exerted any long time together, but are, after a time, received back into the body.

These arms may easily be conceived to be of use to draw in the prey within the compass of the body of the animal; and as soon as it is there, the same contraction of the several rays which serves them to escape danger, and bury themselves in the cavity of the stone, will also serve to hold fast the prey till the creature has fed on it.

Beside these large yellow radiated *Zoophytes*, the top of the stone usually affords a number of others of a blue colour, which stand among a sort of vesicles of water bladders, disposed like clusters of grapes. Philos. Transf. N°. 470. p. 591.

Marygold *Flower*, in zoology. See the article Regulus *Criſtatus*.

MASARINO, in zoology, a name given by the Portugueſe, in the Braſils, to a large bird of the curlew kind, approaching to the gooſe in ſize; and more commonly known by its Braſilian name *curicaca*. See the article Curicaca.

MASCHARADA, in the Italian muſic, is applied to muſic compoſed for the geſtures of pantomimes, buffoons, mimics, and ſuch groteſque characters.

MASLACH, the name of a medicine greatly in uſe among the Turks, and called alſo *Anſion* or *Amphion*. It is prepared principally of opium. They take a dram of it at a time, and ſometimes two or three: They always uſe it when going to battle, and very often as a provocative to venery, as they do the crude opium.

MASLIN. See the article Bullimony.

MASORAH and Masorites. See the article Cabbalists.

MASSALIS, a word by which ſome of the chemical writers have expreſſed mercury.

MASSIMA, in the Italian muſic, is a note or character made in a long ſquare, with a tail to it; thus, . It contains eight ſemi-breves in common time. This character is diſuſed in the modern muſic, for they have found other ways to ſeparate the bars, and to mark the length of notes.

MASTED. A ſhip is ſaid to be *maſted*, when ſhe has all her maſts compleat.

Armed Mast, in a ſhip, one that is made of more than one tree.

Over-Masted, or *Taut*-Masted, is ſaid of a ſhip whoſe maſts are either too long or too big; which makes her lie too much down by the wind, and labour too much *a-hull*.

Spending a Mast, at ſea, is when it is broke by foul weather.

Springing a Mast, at ſea, is when it is cracked in any place.

Under-Masted, or *Low*-Masted *Ships*, ſuch whoſe *Maſts* are either too ſmall, or too ſhort: In which caſe ſhe cannot bear ſo great a ſail as ſhould give her true way.

MASTER (*Cycl.*)—Master *of a Ship of War*, the next officer to a lieutenant; he has under his care and direction every thing relating to the conducting and ſailing of the ſhip, as to determine the courſe ſhe is to ſail, command the ſailors, and give orders for ſteering, trimming and ſailing the ſhip. He is to keep the moſt accurate account of the ſhip's way, and be at all times able to give eſtimate, or prick off her place on the true ſea-chart; and is allowed mates to aſſiſt him in his office.

In merchantmen the *Maſter* is the chief officer.

Master *Load*, in mining, a term uſed to expreſs the larger vein of a metal, in places where there are ſeveral veins in the ſame hill. Thus it often happens, that there are ſeven, ſometimes five, but more uſually three veins or loads, parallel to each other, in the ſame hill. Of theſe the middle vein is always greatly the largeſt. This is called the *Maſter Load*; and the others which lie three, two, or one, on each ſide of this, are called the concomitants of the *Maſter Load*.

The general breadth of the *Maſter Loads*, in Cornwall, is from three to ſeven foot. They are ſeldom larger than this, except in certain peculiar places, as where all the veins meet together, as they ſometimes do, and form a knot, from which they ſeparate again, and each takes its peculiar courſe. The ſize of ſuch a knot is not eaſily determined, and it is uſually very rich in tin, or the other metal of the mine. The ſeveral parts, even of the *Maſter Load*, are not at all regular in breadth, but from ſix foot, it will, in ſome places, dwindle to one foot, or even to an inch broad, in a very ſmall ſpace; but the miners are not diſheartened at this, for they know it will ſoon grow wider again, unleſs really worked out. Phil. Tranſ. N°. 69.

The *Maſter Load* uſually lies in a hard rocky or ſhelfy ſtratum, made up of metalline matter, ſpars, mundic, and other unprofitable ſubſtances, or weeds, as the miners call them, and is, as it were, all along a continued rock; but has many veins and joints, as they are called. In ſome places the matter in which the ore lies is ſofter, and then it is much more eaſily worked. In Cornwall they uſually allow two ſhovel-men to three beele-men or pickers; but where the load runs in a ſofter ſubſtance, there muſt be a greater proportion of the ſhovellers or carriers away.

There is generally water found about the *Loads* of the metal. In moſt places it is met with at ſome feet deep from the *loady* ſurface; and it often runs through the heart of the *Load*, not in a direct channel, but windingly, in and out, inſenſibly through the veins and joints of the *Load*. When the miners have followed a *Load* to ſome depth, and the water begins to be troubleſome, as it generally ſoon is, if there be any in the work, they deſcend to the bottom of the hill, where they have that conveniency, and at the loweſt place begin as little a drift as the convenience of working or driving will permit, ſcarce half ſo big as that for a *Load*; they carry this on, on a level, till they come to the work itſelf. In this the uſe of the dial is needful, which they term *plumming* and *dialling*. See the article Dialling, *Cycl.* and Plumming, *Suppl.*

By this means the exact place of the work is known, where to bring the adit, or where to ſink down to make an air ſhaft. Though the water is troubleſome in the *Loads*, yet there is always one great convenience attending it; which is, that where there is water, there is never want of air for the reſpiration of the miners, and the candles always burn well. But it is alſo to be obſerved, that in a ſoft, looſe, quagmire country, the earth ſometimes falls in after the workmen, in ſuch a manner as, though it does not choak up the whole ſhaft, yet it ſo far ſtops it, as to render the current of air leſs free, and the miners find the utmoſt neceſſity of opening a ſhaft for air to reſpire from the ſurface. If the ſoil be ſo ſoft as not to be able to ſupport itſelf in the working, as is ſometimes the caſe in theſe wet clayey hills, it is neceſſary to prop it up, as they go on, with boards, poſts, and the like. This adds greatly to the expence of mining; but in the working a *Maſter Load*, it is often worth while. When the miners are out of heart at the trouble of walling and propping, on this occaſion, it ſometimes happens, that a dipping of the *Load* carries them down into a firmer ſtratum, and they are at once reliev'd from all that trouble and danger.

Master-*Wort*, in botany, *&c.* See the article Imperatoria.

Master-*Yaw*, a large *Yaw* ſometimes remaining after ſalivation. Se the article Yaws.

MASTICA *De ſobo*, in the materia medica, the name given by the Indians to the ſtone commonly known among authors by the name of *Pedro del Porco*, a ſort of bezoar taken out of the gall-bladder of an Indian boar. The Indians, and many of the European nations, eſteem this one of the greateſt medicines in the world in peſtilential diſeaſes, and the ſmall pox.

MASTIC (*Cycl.*)—The Arabian writers, Aviſenna and Serapio, in their chapters of the turpentine tree, often mention the lentiſk and its reſin, which they ſay was very much like the reſin of the common turpentine tree. But beſide this, Aviſenna has a peculiar chapter on *Maſtic*; whence it ſhould ſeem, that by the name lentiſk they do not mean the tree which produces *Maſtic*, as we do, but ſome peculiar ſpecies of the turpentine tree.

Aviſenna diſtinguiſhes two kinds of *Maſtic*, the one called *rumi*, and the other *cupti*: The *rumi* came from the iſland of Chios, and was white; the *cupti* was or a blackiſh colour, and was brought from Ægypt. See the article Lentiscus.

Mastic is alſo uſed as the name of an herb, otherwiſe called *Marum*. See the article Marum.

Mastiche *Terra*, *Maſtic Earth*, a name given by ſome of the old writers on the materia medica to the Chio earth, or *Terra Chia*. The reaſon of this ſtrange appellation ſeems to have been, that the fineſt *Maſtic* coming from the Iſland of Chios, had obtained the name of *Kio*, or *Chio*, and *Maſtic* and *Chia* being thus become, in one ſenſe, ſynonimous words, the uſe of them was, in this manner, carried much farther, and the earth of that iſland called by the name of the *gum*.

The Arabians ſeem to explain this very well, in their name of this earth; they not calling it *Maſtic earth*, but *thin beled Almaſtichi*, that is, *Terra Regionis Maſtichis*, the earth of the country where *Maſtic* is produced.

MASTICHINA, in botany, a name given by ſome authors to the herb maſtic, or garden *marum*. *Boer.* Ind. 156. See the article Marum.

MASTIGADOUR, or Slabbering-Bit, in the manege, is a ſnaffle of iron, all ſmooth, and of a piece, guarded with pater noſters, and compoſed of three halves of great rings, made into demi-ovals of unequal bigneſs, the leſſer being incloſed within the greateſt, which ought to be about half a foot high. A *Maſtigadour* is mounted with a head-ſtall and two reins. A horſe, by champing upon the *Maſtigadour*, keeps his mouth freſh and moiſt.

To put a horſe to the *Maſtigadour*, is to ſet his croupe to the manger, and his head between two pillars in the ſtable. Horſes that uſe to hang out their tongue, cannot do it when the *Maſtigadour* is on; for that keeps their tongue ſo much in ſubjection, that they cannot put it out.

MASTIGOPHORI, Μαστιγοφοροι, among the Greeks, certain officers appointed to preſerve the peace, and correct ſuch as were unruly at the olympic games. *Potter*, l. 2. c. 22. See alſo Mem. Acad. Inſcript. T. 1. p. 338, 339.

MASTON, in botany, a name by which Pliny and ſome other authors have called the *ſcabioſa*, or *ſcabious*, a blue-flowered plant, common among corn. *Ger.* Emac. Ind 2.

MATCHING, in the wine trade, the preparing veſſels to preſerve wines and other liquors, without their growing ſour or vapid. See the article Wine.

The method of doing it is this: Melt brimſtone in an iron ladle, and, when thoroughly melted, dip into it ſlips of coarſe linnen cloth; take theſe out, and let them cool. This is what the wine-coopers call *match*. Take one of theſe *matches*, ſet one end of it on fire, and put it into the bung-hole of a caſk; ſtop it looſely, and thus ſuffer the *Match* to burn nearly out; then drive in the bung tight, and ſet the caſk aſide for an hour or two. At the end of this time examine the caſk, and you will find that the ſulphur has communicated a violently pungent and ſuffocating ſcent to the caſk, with a conſiderable degree of acidity, which is the gas, and acid ſpirit of the ſulphur. The caſk may, after this, be filled with a ſmall wine, which has ſcarce done its fermentation, and bunging it down tight, it will be kept good, and will

will soon clarify. This is a common and a very useful method; for poor wines could scarce be kept potable, even a few months, without it. Nor could stums be prepared in large quantities without this help. *Shaw's* Lectures, p. 191.

MATER (*Cycl.*)—MATER *Metallorum*, in natural history, a name given by the Saxon mineralists, and those of some other places, to a peculiar kind of marcasite or mundic, which they suppose, according to the expression, to be the mother, or parent of metals.

The marcasite they call by this name is the common yellow kind, but in a foul state, it being usually mixed with some, poor ore of iron, or with some stony matter, which has made it concrete loosely and irregularly, and it is found sometimes formed into thin undulated plates, and sometimes into complex masses; but is always cavernous or spungy, or full of smaller or larger holes. These are often empty; but in some pieces they contain parcels either of pure native metals, or of rich ores. Pieces of native copper are found in some, and ores of iron and tin in others. And it is said in Saxony, that native silver, in thin plates, is found in some few.

MATERFILON, in botany, a name given by some authors to the *jacea nigra*, or common knapweed. Our English name *matfellon* seems a corruption of this. *Ger.* Emac. Ind. 2. See the article JACEA.

MATERIA (*Cycl.*)—MATERIA *Chemica*, a term used by authors to express such bodies as are the peculiar objects of chemical experiments.

The *Materia Chemica*, in a larger sense, takes in all the bodies of the globe, all these being the subjects of chemistry in its extensive sense; but the curious, in chemical researches, may be desirous of knowing in general, what bodies they ought to procure, and have in readiness for them. Dr. Shaw has given a list of these for his portable laboratory, which will serve in general as well as on that particular occasion.

This collection being distributed under proper classes, will come into a small compass, and may be conveniently carried either by land or sea, along with that useful furnace, and its necessary apparatus.

The natural arrangement of the *Materia Chemica* is into the general division of animal, vegetable and mineral substances. But those who are desirous of a larger collection, may enlarge the number of general divisions, according to Becher's method, by which all chemical subjects are arranged into eight general classes; metals, minerals, decompounds, salts, gums, earths, stones, spirits, and oils.

The class of metals contains gold, silver, copper, iron, tin, and lead; and all these are to be kept both in their natural and artificial state; that is, in their ores, and as separated from them for human uses. To these natural metals are to be added the artificial or compound ones, *viz.* pewter, bell-metal, brass, gun-metal, pin-metal, Bath-metal, wells-metal, princes-metal, London-metal, white copper, white gold, and yellow silver. Under minerals are included, antimony, bismuth, zink, marcasite, cobalt, zaffer, smalt, arsenic, manganese, orpiment, mercury, native cinnabar, and sulphur. All these are to be kept both in their natural state as dug out of the earth, and as purified. *Becher's* Phys. Subter. p. 187.

The decompounds of minerals include aurum fulminans, luna cornea, the calxes of gold and silver, ultramarine, distilled verdegrease, burnt copper, putty, or calcin'd tin, sugar of lead, cadmia, tutty, black lead, red lead, litharge, white lead, glass of lead, simple and martial regulus of antimony, glass and cinnabar of antimony, the preparations of quicksilver, as sublimate, precipitate, and the rest. The same sort of arrangement may also take in the several kinds of decompounds of animal and vegetable substances. *Shaw's* Port. Laborat.

The class of salts takes in sea salt, nitre, alum, vitriol, borax, tartar, sugar, potash, and the compound saline fluxes for stubborn ores. And to these are to be added the tribe of artificial salts, of which number are the tartarum vitriolatum, fixed nitre, soluble tartar, terra foliata tartari, nitrum nitratum, sal ammoniac, Epsom salts, volatile salts, and several others of a similar nature.

Under the gums are ranked pitch, resin, turpentine, wax, camphor, amber, pit-coal, jet, and all bitumens, balsams, and inspissated juices.

Among the earths are taken in ores, washed ores, fluds, calxes of metals, lime, plaster, gypsum, chalk, boles, shells, sand, and the fossils commonly and properly called earths, whether they be of the calcarious or of the vitrescible kinds; that is, whether in the fire they are converted into a sort of lime, or run into a glass.

Stones include flints, pebbles, quarry stone, crystal, talc, the vulgar stones, and all the gems from the diamond down to the spars.

Lastly, under spirits and oils come aqua regia, aqua fortis, oil of vitriol, spirit of salt, spirit of nitre, spirit of sulphur, spirit of alum, spirit of vinegar, spirit of wine, spirit of urine, spirit of tartar, spirit of turpentine, oil of tartar per deliquium; the essential oils of nutmegs, cloves, and the like; the expressed oils of olives, almonds, linseed, and the like; and the compound oils, as butter of antimony, artificial balsams, &c.

It is easy to see that this sort of classing is not fit for the naturalist, who studies bodies for their natural qualities, nor indeed for the nice distinguisher of any kind; but in this manner Becher advises the young operator in chemistry, to procure to himself a sort of artificial alphabet of nature, and this will serve the purpose very well, where no more is meant than a mere *Materia Chemica*, to be put in such order, that it may be readily had recourse to in all its parts. With this the young operator is to proceed regularly, as he would do in learning a language. Forming first syllables out of the joining of two or more letters of this alphabet, and then words, by combining these first sets together, and finally, whole discourses; that is, forming these various simple bodies into mixts, compounds, and decompounds. *Becher's* Phys. Subter. p. 179.

To avoid miscarriages, and prevent being imposed upon, it will be very proper to cultivate a knowledge of the productions of nature in their crude state, and peculiar places of growth, where being first viewed and examined before they are gathered or dug up, an exact knowledge of them, as nature furnishes them, may be procured. For want of this previous qualification, men, otherwise of great sagacity, have erred in their operations, and perhaps blamed the original author of a process, in which they miscarry; while they are all the while using a wrong subject, or an adulterated or imperfect one, instead of the true. From this mistake alone, numberless complaints have arisen of the failure and uncertain success in the processes and experiments recorded even by the best authors.

The person who would work in chemistry with pleasure and success, should make a sufficiently copious collection of a *Materia Chemica* of this kind, all the particulars of which he is well assured of, as to their genuineness and perfection in their kinds. These being always ready, will prevent the necessity of sending to the druggist at every turn, where the things sent for are often either not to be had, or only in a sophisticated state; when this alphabet of nature, composed of the several materials of chemical researches, is like the letter in a printing-house, distributed and lodged in proper cells, it may readily be drawn out for use as occasion requires. It is impossible to express with how little expence and trouble, yet with how great profit and pleasure, numerous experiments, and those of the most difficult kind, may be made, when the operator has, in this manner, all his materials about him.

Becher tells us, that he has, in this manner, gone through fifty experiments in a day; and, while writing on chemical subjects, if any difficulty or uncertainly occurred, he immediately got up from his desk, made the necessary experiment, and sat down again to write the certain fact: So that he affirms, there was very little more trouble in making the experiment at the fire, than in describing the process by the pen.

MATES, on board a ship, are assistants to the several officers; as *Master's Mates*, *Surgeon's Mates*, *Gunner's Mates*, *Carpenter's Mate*, *Boatswain's Mate*, *Cook's Mate*, *Corporal's Mate*.

MATHEDORAM, a name by which some chemists have called *sal gemm*.

MATITES, in natural history, the name of a stone described by several authors. The characters they give of it are, that it is of a pale greyish colour, and of the form of the nipples of a woman's breast, several of these nipples appearing upon one stone.

There have been many absurd and idle conjectures, as to the origin of this stone; but it may be easy to account for its figure on very plain and natural principles. We find in the earth many stones, resembling exactly the figures of shells of various kinds, and parts of other animals. These have, in general, once been the things they thus represent petrified, or altered into the nature of stone, by the insinuation of stony particles into their pores.

Among these none are so frequent as the remains of the *echini marini*, or sea eggs, as we call them. These we find in various forms; sometimes single spines, sometimes whole shells, and sometimes only parts of shells preserved. It is well known, that all the *echini marini* have spines or spikes, whence they have their name; and in many of the species which we find recent on our shores, these spines are joined to the body of the shell by a small protuberance, which, from its resemblance to a nipple, we call *papilla*. Now we frequently find these papillæ delineated in creux, in pebbles, and other stones, sometimes singly, and sometimes in numbers together, in the form in which they adhered to the shell. We find, in other fossils, that whatever shell, &c. is sometimes delineated in creux on stone, is also sometimes done in the elevated manner; and it is plain, that there needs no more to the formation of one of these *matitæ* than the petrifaction of a piece of the shell of one of those *echini* which have large papillæ, such as those of the red sea, with some of its papillæ upon it. As to the colour, it is not to be limited to grey alone, but may be as various as the colours of stones, since any species of stone may have gone to the formation of it; and whatever colour the stony matter was, of that will the *Matites* be.

MATKNELTZEL, in zoology, the name of a bird approaching to the snipe kind, and called by Gesner *gallinula erythra*; and

and by the common people of Germany, *mattkern*. It is all over of a reddish or ruddy hue, except the belly, which is white; on the back the colour is more dusky, and is variegated with black spots. On the wings the colour is much fairer and clearer, some of the longer feathers of them approaching to the colour of the painters red earth, called reddle. It is common in watery places, in many parts of Germany and Italy. *Ray*'s Ornithology, p. 226.

MATO, in natural history, the name of a tree growing both in the East and West Indies, and bearing a fruit of the size of an apple, and covered with a thick and tough red skin. This is called by some, the wild *mangoustan*. Its fruit perfectly resembles that of the mangoustan in figure, but is not eatable. Mem. Acad. Par. 1699.

MATORIUM, a word used by some of the chemical writers to express the *gum ammoniacum*; and by others *galbanum*.

MATRASS (*Cycl.*)—The *Matrass*, used in assaying, is a vessel of very pure and transparent glass, not too thick at the bottom, which would make it apt to burst in the fire. It is, for this use, to be about eight or ten inches high, and to have an orifice scarce so much as half an inch wide, lest the matters contained in it, being in a violent state of ebullition, should either rise over the mouth of the vessel, or at least be partly thrown out in form of small drops, like a thin rain, which drops always carry some of the metal with them. The bottom is capacious enough, when it will hold an ounce or two of aqua fortis, and the height of the vessel is of farther use in making a greater repercussion of the fumes. The mouth ought also to be turned backwards, in form of a broad lip, that the solutions, when poured out, may not run down the sides of the vessel. *Cramer*, Art Ass. p. 68.

MATRICARIA, *Feverfew*, in botany, the name of a genus of plants, the characters of which are these: The flower is naturally of the radiated kind. Its disk is composed of flosccules, and its outer circle of semi-flosccules, all placed on the embryo seeds, and contained in one common cup, which is of a squammose structure, and hemispheric figure. The embrios finally become seeds of an oblong figure, affixed to the thalamus of the flower. To this it is to be added, that the flowers always grow many together, in a sort of clusters, and the leaves are divided ino somewhat regular segments, standing in pairs over against one another.

The species of *Feverfew*, enumerated by Mr. Tournefort, are these: 1. The common garden *Feverfew*. 2. The garden *Feverfew*, with red stalks. 3. The wild *Feverfew*, with flowers altogether yellow. 4. The sweet-scented *Feverfew*. 5. The double-flowered *Feverfew*. 6. The white-flowered *Feverfew*, with three series of semi-flosccules. 7. The *Feverfew*, with fistular petals. 8. The curled-leav'd *Feverfew*, with the petals of the flower all fistulous. 9. The *Feverfew*, with the marginal petals of the flower flat, the inner ones fistular. 10. The naked-flower'd *Feverfew*. 11. The tanzy-leav'd *Feverfew*, with large flowers, and umbilicated seeds. 12. The tanzy-leav'd *Feverfew*, with smaller flowers, and umbilicated seeds. 13. The buphthalmum-leav'd Pyrenean *Feverfew*. 12. The American *Feverfew*, with leaves like the *ambrosia*, and with small white flowers. *Tourn.* Inst. p. 493.

Feverfew has always been allowed one of the first places among the hysteric and uterine plants. It is prescribed in powder from a scruple to half a dram the dose; but the much better way is in a slight infusion made in the manner of tea. Taken in this easy manner for a continuance of time, it will bring the menses, tho' subject to be interrupted and irregular, to their true period; and will remove a number of complaints, the natural consequence of such an irregularity.

It is also an agreeable carminative and bitter. It strengthens the stomach, and disperses flatulences; and the expressed juice is said to kill worms. Some likewise commend it in disorders of the head, and in all nephritic complaints. Hoffman gives it great praises, used as a febrifuge. We used to keep a simple water and syrup of *Feverfew* in the shops; but at present they are wholly disused, and the dried herb only kept ready for fomentations, and sometimes as an ingredient in clysters.

Many species of this plant are cultivated in gardens, for the beauty of their flowers. They are propagated by sowing them in March, on a bed of light earth; when they are come up, they should be transplanted out into nursery beds, at about eight inches asunder; and in the middle of May they should be removed into the flower beds, where they are to stand. They flower in July and August; but they should not be permitted to seed, which always weakens, and often destroys the roots: So that the stalks should be cut down to the ground, when the flower decays. *Miller*'s Gardener's Dict.

MATRIMONY. See the articles Espousals and Marriage.

MATRISYLVA, in botany, a name by which some authors call the common honey-suckle, or wood-bind, and others the wood-ruffe.

MATRIX, (*Cycl.*) in anatomy. See the articles Womb, Uterus, Foetus, &c. *Cycl.* and *Suppl.*

Matrix *Succini*, in natural history, a name given by Hartman, and some other authors, to a sort of substance resembling fossile wood, or the barks of trees, common in the clifts of the shores of the Baltic, and found in digging all over Prussia. This is the bed in which the fossile amber of that kingdom is lodged, and it is supposed to have no small share in the production or formation of that fossile. The workmen who dig for amber always make this their guide, and follow the veins of it, never searching any where else for the amber. The very surface of this fossile substance is often covered with a kind of amber; but this is poor, and of no value. Many authors have supposed this cortical or wood-like substance to be real fossile wood; but this is an error. The masses of it are too large, ever to have been trees, and their fibres run often to twenty, thirty, or forty foot diameter, in the same unbroken compages. It differs from trees also in this, that as they have been form'd by successive additions of matter by vegetation, their whole bulk is composed of circular strata, if they may be so called, or additions of coats round a medulla or pith; but in this fossile wood, as some have supposed it to be, there is no pith or medulla, no addition of circular coats, but the same vast mass of it is continued to a vast length and breadth, in the manner of an earthy stratum, and is composed of thin laminæ, or plates laid flatwise one over another. Were this substance really formed of the bodies of trees, we should also find in it that variety of fibres which the several parts of wood are known to consist of; but nothing of this kind appears, we see the whole mass, consisting of absolutely the same shaped fibres; and there never was found, in any of this substance, the least resemblance of a knot or leaf, or the pedicle of a leaf, as might well be expected, had leaves ever grown from it. Phil. Transf. N°. 248. p. 14.

The fossile wood, which is truly such, and has been once vegetable matter, whatever part of the world it is found in, agrees in the same general marks of distinction and knots, and other evident proofs of its having been once vegetable are found in all of it; but this *Matrix* of amber, whether found in Prussia, Denmark, or elsewhere, is still of the same kind, and shews none of these characteristic marks of wood. See the article Succinum.

MATTS, on board a ship, a kind of broad, thick clouts, wove out of spun yarn, sinnet, or thrums; and used to preserve the main and fore-yards from galling against the masts at the ties, and at the gunnel of the loof. They also serve to keep the clew of the sail from galling there; as also to save the clews of the fore-sail from doing so at the beak-head and boltsprit.

MATTAGESS, in zoology, the English name of the larger species of the *lanius* or *butcher bird*.

The word *Mattagess* is borrowed from the Savoyards, and signifies the murdering pye; and has been given it from its savage disposition, and its resemblance to the magpye in the shape of its tail.

It is barely of the bigness of a thrush; its beak is moderately long, black, and hooked at the end, but strait all the way to that. Its tongue is bifid and hairy, and there are several black and short bristles at the top of the beak. Its head, back, and rump, are grey. Its chin and belly white, and its throat and breast variegated with dusky streaks. Its feet and legs are black. It is very common in Germany, and is sometimes seen in the northern parts of England, but with us is not very frequent. It lives among low bushes, and builds in them. Its nest is made of moss, wool, and soft herbs, and the tender branches of heath. It has seven young ones at a brood, which are of a greenish colour, and very little resemble their parent. It feeds on thrushes, and smaller birds, and is a very terrible destroyer among them. *Ray*'s Ornithology, p. 53.

MATTHIOLA, in botany, the name of a genus of plants, the characters of which are these: The cup is a cylindric perianthium, is very short, erect, and undivided, and remains after the flower is fallen; the flower is monopetalous, and consists of a very long tube, which dilates, by degrees, into a large and wide mouth, with a smooth or undivided edge. The stamina are five pointed filaments, shorter than the flower. The apices are simple. The germen of the pistil is globose, and is placed beneath the cup. The style is very slender, and of the length of the cup. The stigma is large and obtuse. The fruit is a drupa of a globose figure, containing only one cell, and crowned with the cup. The seed is a globose nut or stone, containing a kernel of the same globose form. *Plumier*, 6. *Linnæi* Gen. Pl. p. 519. *Ponteder*. p. 39.

MATTKEM, in zoology, a common name in Germany for the *matkneltzel*. See the article Matkneltzel.

MATUITUI, in zoology, the name of a Brasilian bird, of the turdus or thrush kind, and of the bigness of the common starling. Its neck is short; its breast large and strong; its legs short, and its beak a little hooked at the end, and of a fine high red. Its head, neck, back, wings and tail, are all of a fine deep brown, variegated with spots of a pale yellow. Its throat is yellow, and its breast and belly white; a little spotted with brown. Its thighs are grey. *Marggrave*'s Hist.

Hist. Brasil. See the article CURICACA, where *Matuitui* is corruptly printed *Matrictici*.

MATURAQUE, in natural history, the name of an American fish, of the harengiform kind, and having only one short fin on the back. It seldom grows to more than four inches long, and is somewhat flattish, but not very broad. Its head is very broad, and covered with a shelly crust. Its lower jaw is something longer than the upper, and has several very sharp teeth, usually six in number. The upper jaw has a larger number, but they are small. Its gills are large, and its tail is made of a somewhat square fin, a little rounded at the extremity. Its scales are large, and very regularly arranged. Its head, back, and the upper part of its sides, are black, and its belly of a hoary white, and its fins are all black. It is caught in lakes, not in rivers, and is a well tasted fish. *Willughby*, Hist. Pisc. p. 235.

MAUDIHOCA, the *Cassada*, or the poisonous root of which bread is made in many parts of the West Indies. See the article MANIHOT.

MAVIS, in zoology, the common name of the song-thrush, or throstle, called by authors the *turdus viscivorus minor*, to distinguish it from the larger species, called in English the *missel bird*; and usually known among us also by the simple name *thrush*. It is called *viscivorus* by authors, from its resemblance in colour to the other *viscivorus*, not from its feeding on the misletoe-berries, as that does.

It is much smaller than the missel bird, and of a middle size between the fieldfare and redwing. Its back is of a greyish brown, somewhat like the colour of the Spanish olives; its belly white, and its breast yellowish, and spotted with brown and blackish spots, and it is spotted round about the eyes; its under small feathers of the wings are of a yellowish or reddish brown, and those under the tail whitish. Its legs are brown. It feeds on worms, snails, and small insects, and remains with us the whole year. It builds with moss and stubble, and lines the nest with mud. On this it lays five or six eggs, which are of a bluish green, variegated with a few black spots. It sits on hedges and bushes, and sings very agreeably. *Ray*'s Ornithology, p. 138.

MAUMY *Soil*, in agriculture, an earth consisting of a white marly clay, chalk, and sand, which causes it to work very short, as the farmers call it, when any thing dry. This sort of land is usually sowed with wheat, miscellan, or barley, and requires the same tillage that the clay land does, and must be kept dry and warm.

Its most proper manure is the rottenest dung. As they frequently sow beans next after wheat in clayey grounds, so in these they choose to sow peas, chusing a fair and settled season for their seed-time; for if there happen a smart shower soon after their sowing, the earth will bind so firmly together after it, that most of the seed will be lost. *Plot*'s Oxfordshire, p. 246.

MAUND, in our old writers, a kind of great basket or hamper, containing eight bales, or two fats: It is commonly a quantity of eight bales of unbound books, each bale having one thousand pounds weight. Book of Rates, p. 3. *Blount*.

MAUROUSE, the name of a creature of the deer kind, mentioned by Josselyn. It seems to be the same with the *Dama Virginiana* of Mr. Ray, one of which creatures was, in his time, kept alive in St. James's park. See the article DAMA. This is not certain, however; for Josselyn's description is very imperfect; he only says it is like the moose-deer, but is small, and has small horns.

MAUZ, a name used by some authors for the *musa*, or plantain-tree. *Alpin*. Egypt. p. 78.

MAXILLA (*Cycl.*)—MAXILLÆ *Quartus*, in anatomy, a name given by Vesalius, and some others, to one of the muscles of the lower jaw, commonly known by the name of the *digastricus*, and called by Albinus, *biventer maxillæ inferioris*.

MAXILLAM *Attollens Tertius*, in anatomy, a name given by Riolanus, and some others, to a muscle of the face, more generally known by the name of *masseter*.

MAXILLARY (*Cycl.*)—MAXILLARY *Bones*, *Maxillaria ossa*. The *maxillary* bones, or great bones of the upper jaw are two in number, situated one on each side, in the anterior and middle part of the face; their conformation is very irregular, and they are of very considerable extent. Anatomists generally divide them into the external and internal sides. By the external side they mean all that appears in an entire skull, without taking in the arch of the palate, and by the internal side, that which makes part of the arch of the palate, and all that is turned to the *septum narium*. The separation of this bone, by a small transverse suture behind the *foramen incisorium*, is seldom found but in young subjects, before the ossification is compleated. The *maxillary* bone is almost all compact, and without diploe, except in the alveolary arch, and at the point of the orbitary apophysis.

The *Ossa Maxillaria* are connected with the *os frontis*, *os ethmoides*, *os sphenoides*, *ossa unguis*, *ossa malarum*, *ossa nasi*, *ossa palati*, *vomer*, *conchæ narium inferiores*, and with one another. They assist in forming the organ of mastication, the arch of the palate, the cheeks, the orbits, the nose, &c. *Winslow*'s Anatomy, p. 33. seq.

MAXILLARY *Muscles*, in fish, two large muscles placed under the lower jaw, and serving to move it; these, with the two hypophthalmic muscles, which are placed under the eyes, are the four cephalic muscles of fishes, according to authors.

MAXIMIS ET MINIMIS. For the *method of Maximis & Minimis*, see the article MAXIMUM, *Cycl.* and *Suppl.*

MAXIMUM (*Cycl.*)—The fluxion of the base of a curve, or of its abscissa being given, when the fluxion of the ordinate vanishes, the tangent becomes parallel to the base, and the ordinate, most commonly, is a *Maximum* or *Minimum*, according to the rule given by authors on this subject, and mentioned in the Cyclopædia, under this head. But it is to be observed, that if the second fluxion of the ordinate vanish at the same time, and the third fluxion be real, this rule does not hold; for the ordinate is, in that case, neither a *Maximum* nor a *Minimum*. If the first, second, and third fluxions vanish, and the fourth fluxion be real, the ordinate is a *Maximum* or *Minimum*. The general rule given by Mr. Maclaurin, is, that when the first fluxion of the ordinate, with its fluxions of any subsequent successive orders, vanish, and the number of all these fluxions that vanish is odd, then the ordinate is a *Maximum* or *Minimum*, according as the fluxion of the next order to these is negative or positive. But if the number of all the fluxions of the ordinate, of the first and subsequent successive orders that vanish, be an even number, the ordinate is then neither a *Maximum* nor a *Minimum*. See Treat. of Fluxions, B. 1. c. 9. and B. 2. c. 5. art. 859. seq. The greatest and least ordinates are likewise discovered in some cases, by supposing $\dot{y}$ to be infinite in respect of $\dot{x}$. But there are several exceptions to this rule. See *Maclaurin*, loc. cit. art. 262, 865.

A late author has formed some objections to the universality of Mr. Maclaurin's rule. See the Harmony of Antient and Modern Geometry, by Mr. *Paman*, Lond. 1745. 4°. in the Preface.

MAXY, in mineralogy, a name given by some to mundic, a sulphureous mineral, common in the tin mines of Cornwall, and elsewhere. *Boerhaave*, Chem. p 99. n.

MAY *Dew*. See the article ROS *Mayalis*.

MAYA, in natural history, a name given by the people of the Philippine islands to a small species of sparrow, much less than ours, and very common among them. It feeds on rice, and is very destructive of it.

MAZA, a name given by the antients to a sort of food, in common use among the poorer sort of people. It was made of the meal of parched barley, sprinkled with some liquid, and was eaten with honey or with defrutum.

Hippocrates every where speaks of this as of a coarse kind of bread, and advises the changing the common finer bread, in the spring season, for this coarser kind, as a thing very conducive to health. He seems every where to consider bread as the drier, and *Maza* as the moister diet.

MAZA, Μαζα, among the Athenians, a sort of cake, which was the common fare of such as were entertained at the public expence in the common hall, or *prytaneum*. *Potter*, Archæol. Græc. l. 1. c. 25. T. 1. p. 136.

These cakes were made of flour boiled with water and oil. *Pitisc.* Lex. Ant. in voc.

MAZONOMUS, among the antients, a very large dish, commonly of wood, in which the *Maza* was served. *Pitisc.* Lex. Ant. in voc. See the article MAZA.

MAZORAH, among the Jews, denotes the science of reading the scriptures. See the article CABBALA.

MAZUR, a species of birds, which the Arabian sailors esteem very lucky, because it lays its eggs close by the sea shore before a tract of good weather; so that when these are observed, they promise themselves a safe voyage. They also pretend that this bird gives notice to sailors, when the ship approaches any danger, by flying and fluttering up and down. *Hofm.* Lex. in voc.

MEADOW *Land*. Too much water, and too little, are equally prejudicial to *Meadow* grounds. The best lands for *Meadow* pasture are either low lands, or hanging grounds, where there is a rich soil and a moist bottom; especially where any little brook, or running spring, may be brought over it; and where there is some descent in the *Meadow*, that the water may not lodge on it. These *Meadows* are much better for the farmer than those near large rivers, where great crops are often lost. *Mortim.* Husb.

MEADOW-*Saffron*, *Colchicum*. See the article SAFFRON.

MEAL. The *Meal* or flour of England is the finest and whitest in the world. The French is usually browner, and the German browner than that. Our flour keeps well with us, but in carrying abroad it often contracts damp, and becomes bad. All flour is subject to breed worms; these are white in the white flower, and brown in that which is brown; they are therefore not always distinguishable to the eye; but when the flour feels damp, and smells rank and musty, it may be conjectured that they are there in great abundance.

The colour, and the weight, are the two things which denote the value of *Meal* or flour; the whiter and the heavier it is, other things being alike, the better it always is. Pliny mentions these two characters as the marks of good flour, and tells us, that Italy, in his time, produced the finest in

the world. This country, indeed, was famous before his time for this produce; and the Greeks have celebrated it; and Sophocles, in particular, says, that no flour is so white, or so good, as that of Italy. The corn of this country has, however, lost much of its reputation since that time; and the reason of this seems to be, that the whole country being full of sulphur, alum, vitriol, marcasites, and bitumens, the air may have, in time, affected them so far, as to make them diffuse themselves through the earth, and render it less fit for vegetation; and the taking fire of some of these inflammable minerals, as has sometimes happened, is alone sufficient to alter the nature of all the land about the places where they are. *Desland.* Trait. Phys.

The flour of England, though it pleases by its whiteness, yet it wants some of the other qualities valuable in flour; the bread that is made of it is brittle, and does not hold together, but after keeping a few days becomes hard and dry, as if made of chalk, and is full of cracks in all parts; and this must be a great disadvantage in it when intended for the service of an army, or the like occasions, where there is no baking every day, but the bread of one making must necessarily be kept a long time.

The flour of Picardy is very like that of England, and after it has been kept some time, is found improper for making into paste or dough. The French are forced either to use it immediately on the grinding, or else to mix it with an equal quantity of the flour of Bretany, which is coarser but more unctuous and fatty; but neither of these kinds of flour keep well.

The flour of almost any country will do for the home consumption of the place, as it may be always fresh ground; but the great care to be used in selecting it is in order to the sending it abroad, or furnishing ships for their own use. The saline humidity of the sea air rusts metals, and fouls every thing on board, if great care be not taken in the preserving them. This also makes the flour damp and mouldy, and is often the occasion of its breeding insects, and being wholly spoiled.

The flour of some places is constantly found to keep better at sea than that of others; and when that is once found out, the whole caution needs only be to carry the flour of those places. Thus the French find that the flower of Poitou, Normandy, and Guienne, all bear the sea carriage extremely well, and they make a considerable advantage by carrying them to their American colonies.

The choice of flour for exportation being thus made, the next care is to preserve it in the ships; the keeping it dry is the grand consideration in regard to this; the barrels in which it is put up ought to be made of dry and well-seasoned oak, and not to be larger than to hold two hundred weight at the most. If the wood of the barrels have any sap remaining in it, it will moisten and spoil the flour; and no wood is so proper as oak for this purpose, or for making the bins and other vessels for keeping flour in at home, since, when once well dried and seasoned, it will not contract humidity afterwards. The beach wood, of which some make their bins for flour, is never thoroughly dry, but always retains some sap. The fir will give the flour a taste of turpentine; and the ash is always subject to be eaten by worms. The oak is preferable because of its being free from these faults; and when the several kinds of wood have been examined in a proper manner, there may be others found as fit, or possibly more so than this for the purpose. The great test is their having more or less sap. See the articles FLOUR and WOOD.

MEAL *worm.* See the article WORM.

MEAN (*Cycl.*)—MEAN *Anomaly*, in astronomy. See the article ANOMALY, *Cycl.*

MEAN $\left\{ \begin{matrix} \textit{Conjunction,} \\ \textit{Opposition,} \end{matrix} \right\}$ in astronomy, is when the *mean* place of the sun is in $\left\{ \begin{matrix} \textit{Conjunction,} \\ \textit{Opposition,} \end{matrix} \right\}$ with the *mean* place of the moon in the ecliptic. See the articles CONJUNCTION and OPPOSITION, *Cycl.*

MEAN *distance of a planet from the sun*, in astronomy, is the right line drawn from the sun, to the extremity of the conjugate axis of the ellipsis the planet moves in; and this is equal to the semitransverse axis, and is so called because it is a *mean* between the planets greatest and least distance from the sun.

MEAN *Motion*, in astronomy, that whereby a planet is supposed to move equally in its orbit, and is always proportional to the time.

MEASURE (*Cycl.*)—We have lately had some accurate comparisons between some of the French weights and measures, and those of England, the result of which is, 1. The Paris half toise, as set off on the standard kept in the Royal Society, contains of English inches, by the same standard, 38.355. whence it appears, that the English yard and foot is, to the Paris half toise and foot, nearly as 107 to 114; for as 107 to 114, so is 36 to 38.35514.

2. The Paris two marc, or sixteen ounce weight, weighs English Troy grains 7560; whence it appears, that the English Troy pound of twelve ounces, or 5760 grains, is to the Paris two marc, or sixteen ounce weight, as 16 to 21; that the Paris ounce weighs English Troy grains 472.5; and that consequently the English Troy ounce is to the Paris ounce, as 64 is to 63.

3. The English avoirdupois pound weighs Troy grains 7004; whence the avoirdupois ounce, whereof sixteen make a pound, is found equal to 437.75 Troy grains. And it follows, that the Troy pound is to the avoirdupois pound, as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636; that the Troy ounce is to the avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 438. And, lastly, that the avoirdupois pound and ounce, is to the Paris two marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, so is 7004 to 7559.873.

4°. The Paris foot, expressed in decimals, is equal to 1.0654 of the English foot, or contains 12.785 English inches. Phil. Trans. N°. 465. Sect. 5.

MEAT (*Cycl.*)—MEAT, in the manege. See the article DRY *Meat.*

MEB, or *Sea* MEB, in zoology, the name of a water bird of the larus or gull-kind, which is all over of a dusky grey on its upper part; its head is blackish at the top, and the beak is red. The legs are short and black, and the wings very long, reaching beyond the tail when folded.

MECAXOCHITL, in the materia medica, the name of the *piper longum humilius*, or small American long pepper. *Dale*, Pharm. p. 286.

MECHANICAL (*Cycl.*)—MECHANICAL *Force.* See the article FORCE, *Appendix.*

MECHANICAL *Operation of Medicines.* See the article MEDICINE.

MEDAL (*Cycl.*)—*Impressions of* MEDALS. A very easy and elegant way of taking impressions of *Medals* and coins, not generally known, is this: Melt a little isinglass glue, made with brandy, and pour it thinly over the medal, so as to cover its whole surface; let it remain on for a day or two, till it is thoroughly dry and hardened, and then taking it off, it will be fine, clear, and hard as a piece of Muscovy glass, and will have a very elegant impression of the coin. *Shaw's* Lectures, p. 430.

Sulphur is sometimes used to take off impressions of *Medals*, coins, *&c.* The method is this: Having made a ledge of clay about the work, whose impression is desired, and carefully oiled the whole, gently pour brimstone melted in a covered vessel, to prevent its firing upon the metal. About the edge of this mould make a border of clay, as before, and lightly oil the internal surface of both; then gradually put into it, to the thickness of about a quarter of an inch, a mixture made up with calcined alabaster and water, to the consistence of stiff honey. This soon growing hard, may be taken out of the mould, and gives figures of the coin or *Medal.* *Boyle's* Works abr. vol. 1. p. 151. A method somewhat different is described in the article BRIMSTONE.

We have an easy method of procuring the true impression or figure of *Medals* and coins, by Mr. Baker in the Phil. Trans. N°. 472. Sect. 13.

Take a perfect and sharp impression in the finest black sealing-wax, of the coin or *Medal* you desire. Cut away the wax round the edges of the impression; then with a preparation of gum-water, of the colour you would have the picture, spread the paint upon the wax impression with a small hair pencil, observing to work it into all the sinking or hollow places, these being the rising parts of the *Medal*; and the colouring must be carefully taken from the other parts with a wet finger. Then take a piece of very thin post paper, a little larger than the *Medal*, and moisten it quite through. Place it on the wax impression, and on the back of the paper lay three or four pieces of thick woollen cloth or flannel, of about the same size. The impression, with its coverings, should be placed between two smooth iron plates, about two inches square, and one tenth of an inch thick. These must be carefully put into a small press, made of two plates of iron, about five inches and an half long, one inch and a half wide, and half an inch in thickness, having a couple of long male screws running through them, with a turning female screw on each, to force the plates together. These being brought evenly together, by means of the screws, will take off a true and fair picture of the *Medal*; which, if any deficiencies should appear, may easily be repaired with a hair pencil, or pen, dipped in the colour made use of.

If a relievo only be desired, nothing is necessary, but to take a piece of card, or white paste-board, well soaked in water, then placing it on the wax mould, without any colouring, and letting it remain in the press for a few minutes, a good figure will be obtained.

This Method of taking off *Medals*, *&c.* is convenient, and seems much more so than the several inventions usually practised in sulphur, plaster of Paris, paper, *&c.* wherein a mould must be formed, either of clay, horn, plaster, or other materials, which require a good deal of time and trouble.

Some take impressions on paper from the *Medals* themselves, by passing them through the rolling-press, and colouring them afterwards; but this is not only more difficult, but does great injury to the *Medals*, by impairing the sharpness of their most delicate

delicate and expreffive ftrokes: Whereas wax does not hurt the fineft *Medal* in the leaft degree; and though a brittle fubftance, yet it effectually refifts the force of a downright preffure.

Red feems the beft colouring, and therefore black wax is directed to be ufed; but if the pictures are chofen in black and white, to refemble copper plates, the wax fhould be red; for the wax and paint ought to be of different colours, in order to diftinguifh when the colour is laid on properly, or rightly cleared away.

The fubftance of *Medals*, being metalline, is liable to be corroded; and the figures being raifed, are alfo liable to be effaced by friction. Hence it is rare to find any perfectly preferved. Gems are not fubject to thefe inconveniencies. See the article GEM.

MEDEA, the name of a ftone defcribed by Pliny and the antients. They fay it was black, and was variegated with gold-coloured veins, and that, when rubbed in water, it yielded a yellowifh red juice, which had the flavour of wine. We know no ftone at prefent anfwering thefe characters. Rulandus, indeed, mentions a kind of black hæmatites, or blood-ftone, which tinges water to a faffron colour. This account he takes from Encelius; but this wants the much greater character, of giving it the tafte of wine.

MEDENA, a word ufed by Paracelfus to exprefs an inveterate kind of ulcer.

MEDEOLA, in botany, the name given by Linnæus to a genus of plants, called *falfa* by other authors. The characters are thefe: There is no cup, but fome have erroneoufly taken the flower for a cup, and have defcribed it under this name, and allowed no flower. The flower confifts of feveral petals, of an oblong oval figure, equal in fize, and ftanding expanded, with their ends often bent backwards. The ftamina are fix fubulated filaments, of the length of the flower. The antheræ are incumbent. The piftil has three corniculated germina. The ftyles are of the fame number, one terminating each germen. The ftigmata are thick and crooked. The fruit is a roundifh berry, dividing into three parts, and containing three cells. The feeds are fingle, and of a cordated form. *Linnæi* Gen. Plant. p. 154.

MEDIALE, in botany, a name given by the antients to the central part of any tree. It is fometimes ufed to fignify the fpungy pith that fils up the young branches of a tree, as in the elder, and the like. And fometimes for the firm and hard fubftance, called the heart of the wood, and found to be much harder than any other part of it. Thus the name of *tree*, to which the word *Mediale* is annexed, muft be the means of explaining what is meant by the word, whether a fpongy pith, or a found and hard wood. The moft accurate writers, however, make a diftinction which ought to be kept up, that is, the calling the heart, or found internal part of wood, only *Mediale*, and the fpungy part within the elder, *&c. Medulla*.

MEDIANTE, in mufic. *The Mediant of a mode* is that note which is a third higher than the final; or that which divides the fifth of every authentic mode into two thirds. See the articles MODE and THIRD.

This term is chiefly in ufe among the French. See *Broffard*, Dict. Muf.

MEDIATORS *of Queftions*, in our old writers, were fix perfons authorized by ftatute, who, upon any queftion arifing among merchants, relating to any unmercable wool, or undue packing, *&c.* might, before the mayor, or officers of the ftaple, upon their oath, certify and fettle the fame; to whofe order and determination therein, the parties concerned were to give entire credence, and fubmit. 27 Edw. 3. Stat. 2. c. 24. *Blount*.

MEDIATORS, Μεσαζοντες, under the emperors of Conftantinople, officers of ftate who had the direction of all affairs tranfacted at court. Their chief, or prefident, was called *megas mefazon*, Μεγας μεσαζων, and anfwered to the prime or grand vifier of the Turks. *Hofm.* Lex. in voc.

MEDICA, *Lucerne*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the papilionaceous kind, and its piftil, which arifes from its cup, becomes finally a feed-veffel, of the fhape of a fnail, containing ufually kidney-fhaped feeds.

The fpecies of *Medica*, enumerated by Mr. Tournefort, are thefe: 1. The great upright *Medica*, with purple flowers. 2. The great upright *Medica*, with violet-coloured flowers. 3. The great upright *Medica*, with yellow flowers. 4. The great upright *Medica*, with variegated flowers of violet colour and yellow. 5. The wild *Medica*, with faffron-coloured flowers. 6. The wild *Medica*, with pale yellow flowers. 7. The wild *Medica*, with bluifh green flowers. 8. The fmall wild *Medica*, with blue and yellow flowers. 9. The fea *Medica*. 10. The *Medica*, with broad fcutellated fruit. 11. The *Medica* with orbiculated fruit. 12. The *Medica* with fmooth leaves, marked with black fpots, and with echinated fruit. 13. The echinated-fruited *Medica*, with fmooth leaves, without the black fpots. 14. The great *Medica*, with turbinated fruit. 15. The hairy *Medica*, with very rigidly echinated fruit. 16. The hairy echinated *Medica*. 17. The fmalleft echinated *Medica*. 18. The little coronated *Medica*. 19. The many fruited *Medica*, with obtufe, and not crenated leaves. 20. The many-fruited *Medica*, with obtufe crenated leaves. 21. The prickly two-fruited fnail *Medica*, with elegantly divided leaves. 22. The perennial *Medica*, with the ciliary fruit. 23. The perennial fhrub *Medica*, with orbiculated fruit. 24. The many-fruited orbicular-headed *Medica*, with a fmaller fruit. 25. The orbiculated *Medica*, with a broad fruit, with a fingle voluta. 26. The fmaller orbiculated prickly *Medica*, with a fingle large voluta. 27. The elegant orbiculated *Medica*, with the fruit rugofe at the edges. 28. The barrel-fruited *Medica*, with the circles of the fruit wrinkled on each fide, and turning black with age. 29. The larger and fmaller fmooth *Medica*, with the turned fruit. 30. The elegant *Medica* of Catalonia. 31. The prickly cochleated *Medica*, with large echinated fruit, turbinated at each end, and armed with fpines turning backwards. 32. The *Medica* with the leaves and feeds of the heart-leav'd *Medica*, and with harder fruit. 33. The large double-fruited prickly barrel-headed *Medica*. 34. The two-fruited prickly *Medica*, with oval fruit, and fhort rigid fpines. 35. The many-fruited prickly barrel-headed *Medica*. 36. The leaft, hairy and prickly barrel-fruited *Medica*. 37. The great prickly fea *Medica*. 38. The *Medica* with lax fruit, of the fmall echinated kind, but with prickles not ftanding out. 39. The foft and hoary-leav'd hop *Medica*, with heart-fafhion'd feeds. 40. The great fruited *Medica*, with the prickles of the head turning both upward and downward. 41. The *Medica* with a large fruit, with the prickles turning all upwards. *Tourn.* Inft. p. 413. See the article LUCERNE.

Malus MEDICA, in botany, a name given by fome authors to the citron tree. *Ger.* Herb. 1287.

MEDICAL *Stones*. See the article STONE.

MEDICAGO, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the papilionaceous kind, and its piftil, which arifes from the cup, finally becomes a plain orbiculated fruit, of a fort of falcated fhape, and containing one kidney-fhap'd feed.

The fpecies of *Medicago*, enumerated by Mr. Tournefort, are thefe: 1. The annual trefoil-like *Medicago*. 2. The Spanifh *Medicago*, with the appearance of the kidney vetch. 3. The cretic *Medicago*, with the appearance of the kidney-vetch. And 4. The hoary trifoliate fhrubby *Medicago*, commonly called the Cytifus with crooked pods. *Tourn.* Inft. p. 412.

MEDICINES (*Cyc.*)—By *Medicines* is meant whatever corrects a depraved or vitiated conftitution of body, and reftores it to a heathful ftate: So that they differ from aliments, which preferve the body in a found ftate, whereas *Medicines* reftore it when impaired; and from poifons, which tend to deftroy the body. All the parts of diet may indeed be termed alimentary *Medicines*, in as much as they may ferve to confirm health, againft the firft approaches of a difeafe; as poifons, which are always detrimental to the body, have been called deleterious *Medicines*.

Medicines are either fimple, or compound: Simple *Medicines* are thofe which are formed fpontaneoufly, or by the affiftance of nature alone; and thofe are called compound, which are owing to the art and induftry of men; and to the mixtures of various fimples put together.

The principal differences of fimple *Medicines* are taken either from their form and texture, or from their virtues. In refpect to their texture, they are divided into minerals, vegetables, and animals; each of which divifions is termed a clafs, kingdom, or family.

In what the antients have left us concerning the *Medicines* they ufed, there is the utmoft confufion and obfcurity; the fame fubftance is frequently called by many different names; fome *Medicines* are barely mentioned by them, without any account of their nature or defcription; and in regard to many others, the virtues afcribed by them to one fimple, have been, by later writers, attributed to others. To clear up, and fet right all thofe difficulties, at this time, would be a tafk as difficult as it would be ufeful. So great and fo many virtues are afcribed, by different authors, to particular *Medicines*, that, if they could be depended on, each ought to be looked on as an almoft univerfal remedy; but as many of thefe virtues are merely imaginary, it requires even the greateft caution to diftinguifh the fictitious from thofe which truly belong to them; and though the knowledge of the virtues of *Medicines* be at this time carried to a very great length, there are neverthelefs many things remaining yet to be difcovered, and room enough ftill to enrich the fcience with new fpecific remedies; nor will the judicious phyfician find lefs worthy employment for his thoughts, in endeavouring to determine the manner in which thofe *Medicines* act, whofe effects are already known, and to afcertain the fafeft and beft methods of adminiftring them. *Geoffroy*, Tract. p. 2.

Such *Medicines* as are of a terreftrial, or other the like nature, and will not diffolve in water, the new Difpenfatory of the college has ordered to be prepared in the following manner: They are firft to be pounded in a mortar, and then levigated with a little water, upon a hard and fmooth marble, into an impalpable powder, and afterwards dried upon a chalk ftone, and

and then set by for a few days, in a warm, or at least a very dry place. In this manner are to be prepared amber, antimony, bezoar, which should be levigated with spirit of wine instead of water, blood-stone, calamy, first calcined for the use of the makers of brass, chalk, coral, crabs claws, crabs eyes (so called); egg-shells cleansed from the membrane adhering to them by boiling in water, oyster-shells first cleansed, pearls, verdegrease, tutty.

In antimony, calamy, and tutty, singular care ought to be taken to reduce them to the most subtle powder that can be. *Pemberton*'s College Disp. p. 145.

Mechanical Operation of MEDICINES. To account for the operations of *Medicines* mechanically, seems to have been the favourite scheme of physicians and physiologers of the last and present century. Stahl and his disciples reject these accounts, and think them sufficiently refuted by the operation of opium, and of astringents. One grain of opium, properly taken, will, for a time, asswage pains all over the body. A very few grains of crocus martis astringens sometimes stop an hæmoptysis, before they can be supposed to have entered into the humours of the body. Is it not past all belief, say they, that so few grains mixed with so many pounds of fluids, should retain any mechanical force, especially as it is well known that astringents lose their force by dilution. They farther urge, that the various effects of the same *Medicine* are a refutation of the mechanical hypothesis; thus emetics sometimes purge, and *vice versa*; astringents encrease hæmorrhages; opium excites alacrity in some, instead of stupifying. Again, the sight, or even bare imagination of some *Medicines*, will produce a sensible effect on the body, without any contact. Stahl and his followers therefore hold, that *Medicines* operate chiefly by exciting the vital sense; and that this is the chief effect of *Medicines*, even where they seem most to act mechanically. See *Juncker*'s Consp. Therap. p. 3. seq.

Hoffman, Heister, and others, have attacked the hypothesis of Stahl. We shall not pretend to give any farther account of the controversy. Perhaps in this, as in others, there may be a good deal of logomachy. Strictly speaking, mechanical principles must be insufficient to account for the operation of *Medicines*, as this sometimes undoubtedly depends (in the *primæ viæ* at least) on chemical principles; and no body has hitherto been able to account mechanically for the phænomena of chemistry. The laws of the *minima naturæ* have not hitherto been reduced to those of the pressure and impulse of large sensible masses. And perhaps when the laws, that obtain in the minute parts of matter, have been found, we shall still be at a loss to account for all the phænomena of animated bodies, particularly the human.

Heister says, Stahl pretends that the rational soul and nature are synonimous terms; and that it is the rational soul which formed the fœtus in the womb, and which directs all vital, animal, and natural actions, to the preservation of the body; hence sometimes exciting evacuations, sometimes spasms, to get rid of disorders. *Heister*, Differt. de Medicin. Mechan. præstantia in Compend. Medicin. Practic. where he endeavours to refute the Stahlians.

Juncker, who wrote according to Stahl's principles, does not deny that there is something mechanical in the operation of *Medicines* independantly of the will or spontaneity of nature; but he asserts that their chief operation is owing to nature, which makes use of the remedy to attain its end. His words are, *Operationem Medicamentorum ab ipsa natura gubernari innumeræ confirmant Observationes. Licet enim non negamus, subesse interdum actioni eorum aliquid mechanici, a naturæ arbitrio non pendentis, tanti tamen hoc non est habendum, ut operandi modus illi maxime adscribi mereatur. A potiori enim fit denominatio, & natura utitur remedio ad finem suum.* *Juncker*, Conspect. Therap. p. 1, 2.

A late author observes, as to *Medicines*, that let what disease soever be named, and any *Medicine*, as universally useful in it, yet he can shew circumstances of patients, or of the disease, where that *Medicine* would be very improper. He mentions several instances of this kind. See Medic. Ess. Edinb. vol. 1. p. 267. seq.

MEDICINES *from Metals*. See the article METALS.

Pocket MEDICINES, in surgery, are such necessary remedies as the surgeon ought never to be without; but always to carry in a convenient case or box about him. These are the common digestive ointment, and the brown or Ægyptian ointment, for cleansing and digesting foul ulcers, and some vulnerary balsams, as the *linimentum Arcæi*, or the balsam of Peru, of Gilead, or Capivi, or the Samaritan balsam: To these must also be added a plaster or two, as the diachylon, or stypticum Crollii, since one or other of these is almost constantly wanted. Neither should there be wanting a piece of blue vitriol for the taking down luxuriant flesh, and to stop hæmorrhages; but if vitriol is wanting, burnt alum, red precipitate, the infernal stone, or any other corrosive *Medicine*, will supply its place in corrosive intentions, and the last will also serve to open abscesses, to make issues, and perform many other operations of that kind. With these there should always be kept in readiness also a quantity of scraped lint, that the surgeon may be able to give immediate assistance to wounded persons, since, if he is unprepared for this, they may be easily taken off by an hæmorrhage, a circumstance which ought also to prevail with the surgeon never to be wholly unprovided with bandages. *Heister*'s Surg. p. 11.

MEDIMNUM, Μέδιμνον, among the Greeks, a measure of capacity, holding six Roman *modii* or bushels. *Danet*. in voc.

MEDINE, an Egyptian piece money, of iron silver'd over, and about the size of a silver three-pence. *Pocock*'s Egypt. p. 173.

MEDINUS, a name given by some to the *medus*, a stone celebrated by the writers of the middle ages for many imaginary virtues. See the article MEDUS.

MEDITRINALIA, among the Romans, feasts instituted in honour of the goddess *Meditrina*, and celebrated on the 30th of September. They were so called from *medendo*, because the Romans then began to drink new wine, which they mixed with old, and that served them instead of physic.

MEDIUM, in botany, a name given by Dioscorides to the violet, and by Lobel, to the sea flag-flower, or *iris maritima narbonensis*. *Ger*. Emac. Ind. 2.

MEDLAR, *Mespilus*, in botany. See the article MEPSILUS. We have two kinds of *Medlar* propagated very frequently in orchards, for the sake of their fruit; the one is the common *Medlar*, or, as it is called by some, the Nottingham *Medlar*; the other the Dutch *Medlar*. The first of these was once almost the only kind known in England; but since the other has been introduced, it is found so much superior in the size, and flavour of the fruit, that it is now almost the only kind thought worth the cultivating.

They are propagated by budding or grafting them upon the hawthorn, or the pear stock, upon either of which they take very well, and may be afterwards transplanted into the fruit-garden, either as standards, or trained up against an espalier, in both which methods they will succeed very well. If the larger sort are trained up in an espalier, the fruit will be much larger; but great care must be taken in the pruning, not to shorten the bearing branches, for the fruit is almost all produced at the extremities of these. The *Medlar* will grow on any soil; but on a moist and strong soil, the fruit will grow larger, and on a dry one, it will, though smaller, be much better tasted. *Miller*'s Gardener's Dict.

The fruit should be suffered to remain on the branches till October, at which time it will begin to fall of itself, and it should then be gathered in the middle of a dry day, and laid up in a dry place till soft, and beginning to decay, which is usually about a month after it is gathered; at this time they are fit for eating, for, till they begin to decay, they are too harsh for the palate.

MEDOKINA, in natural history, the name of a species of oyster. See the article OSTREA.

MEDULLA (*Cycl.*)—MEDULLA *Spinali*. In fishes, the spinal marrow does not run through the middle of the vertebræ, as it does in other animals, but is carried through a whole series of the apophyses which stand on the upper part of the bone, and are therefore called the *apophyses dorsales*, to distinguish them from the others, which their situation occasions to be called the lateral and ventral. All these dorsal apophyses of the vertebræ are hollow at their base, and by that means afford a continued channel for this marrow. The bases of the lower apophyses reaching from the anus to the tail, have also the same sort of hollow at their base; but this serves only for the passage of the larger blood-vessels.

MEDUS, or MEDINUS, a name given by the writers of the middle ages to a stone brought from Media, of which they say there were two kinds, the one black, and the other green. They attribute many strange virtues to these stones; the black they say was a fatal poison when taken inwardly, but that if wetted with milk, and rubbed upon the skin of a woman with child, it caused her to bring forth a boy. This, and a number of other as probable virtues, did these ignorant and fanciful writers bestow at pleasure on stones never known to the world before, and of which themselves gave no descriptions. This seems to be only a false history of the *Medea* of Pliny.

MEDUSÆ *Caput*, in natural history, a name given by authors to the *stella marina*, called by some, from its various branchings, *stella arborescens*. Rumphius, Gesner, and many other authors, have described this strange fish in its recent state, and in the acta eruditorum, we have an accurate figure, and a very remarkable account of one which was found fossile, and preserved in a remarkably perfect manner in stone.

The stone in which it was found was of the fissile or slaty kind, and it was so large as to extend over a piece of this stone of four foot in length, and between three and four in breadth. The body of the fish, from which all the rest seemed originally to have arisen, lay at one corner of the stone, and the arms extended themselves lengthways in a very distinct and natural manner the whole length of the stone; and from these there parted, on every side, other smaller ones, and these were finally divided into others more minute, in such a manner as to represent the nicest painting. Act. Erudit. Ann. 1725. p. 377.

The study of fossils is more improved by this single specimen, than by thousands of others, and by the reasonings of almost as many authors. The fossils called *entrochi*, have always perplexed the writers on these subjects to account for; some having judged them a sort of stony vegetables; some *lusus naturæ*; and others as different things; but in this

this table the whole fish is so perfectly preserved, that there can remain not the least doubt of its being really the *stella arborescens*; and in this both the figure and the author's words exprefs, in the plainest manner possible, that the long arms or branches reaching from one end to the other of the stone, are composed of a number of *entrochi* as it were, tied together in the same manner as the single joints of those *entrochi* which we meet with are to one another; or, in plain fact, that our *entrochi*, which have perplexed us so much to account for their origin, are in reality the fragments of the arms or branches of this fish. These branches in this famous specimen, were composed of what we call *trochitæ*, and had many rudiments of smaller branches, as well as perfect ones, growing from their sides, and would have been so many common *entrochi*, if broken off.

What was most remarkable in this fossil was, however, the separating of smaller branches which ran entire to their ends, and there terminating in an infinite number of small ramifications, all growing from one head; they formed clusters of four or five inches in diameter, and of an inconceiveable beauty, resembling the compound flower of some elegant plant. The matter of the larger branches, when examined, appeared to be the same with that of the common *entrochi*, that is, spar. The author calls it *selenites*, but that was a word indeterminately used by authors, till of late, for all plated and bright fossils.

It is plain that this compleat fish could have no way come into this stone but at the time when it was yet moist and soft; and the author calls it *novum diluvii monumentum*, a new remembrancer of the deluge.

MEER, in mining, a space containing twenty-nine yards in length in any vein. *Houghton*'s compl. Miner in the Explan. of the Terms.

MEER-*Stake*, in mining, is a pin of wood drove into the superficies of the earth, to shew the extent or end of a *Meer* of ground. *Houghton*'s Compl. Miner in the Explan. of the Terms.

MEER-*Swiin*, in zoology, a name given by some to a sea fish, more usually known by the name of *caprifcus*. *Ray*'s Ichthyogr. Append. p. 1. See the article GOAT-*Fish*.

MEGALARTIA, Μεγαλαρτια, in antiquity, a festival in honour of Ceres, being the same with *Thesmophoria*. *Potter*. Arch. Græc. See the article THESMOPHORIA.

MEGALASCLEPIA, Μεγαλασκληπεια, in antiquity, a festival in honour of Æsculapius. See the article ASCLEPIA.

MEIDANS, in the eastern nations, are a sort of country seats, where the greater people have open summer-houses, to which they retire on the three days of the week in which they do not attend the pashas divan, and where they divert themselves with seeing their slaves ride, shoot, and throw the dart, while they are regaling with their pipe and coffee. *Pocock*'s Egypt, p. 184.

MEL, *Honey* (*Cycl.*)—See the article HONEY.

MEL *Cedrinum*, in the materia medica of the antients, a term used to express a sort of liquid manna, used rather as a pleasant sweet in foods, than as a medicine, and which seems to have been the same with the *Mel Roscidum* of Galen, and with the liquid manna of mount Sinai; that mountain having been the place where it was annually collected in large quantities, even in Galen's time; and the account Bellonius gives of the manner of collecting it in his time, agreeing very well with what Galen has left about it. It is, however, an error in Bellonius, to suppose this to be the *terenjabin* of the Arabians, that being evidently a solid, not a liquid substance, and being, from all accounts the same with what is now called, *manna Persicum*, or Persian manna. See the article MANNA *Persicum*.

The *Mel Cedrinum* is a term used only by Hippocrates for this substance, and seems so odd, that many are apt to believe there is an error in the text, and that the author never meant any such thing. Foesius is of opinion, that these ought to be read as two distinct names, with a comma between them, and that the author only meant by them two substances very well known in his time, which were common honey, and the liquid substance called *Cedrinum*, or *Cedria*. See the article CEDRIA.

MEL *Roscidum*, in the materia medica of the antients, a name given to a kind of liquid manna collected in their time, as it is at present, in considerable quantities, on mount Sinai. The monks who collect it call it *terenjabin*, after the name of a kind of manna, common among the Arabians. But this is an error, the terenjabin of those authors not being a liquid manna, but the small round kind, collected from the *albagi maurorum*, and now called *manna Persicum*. It does not appear that the *Mel Roscidum*, or any other species of manna, was used in medicine by the antients; this was esteemed a curiosity, rather than a thing of any use, by Galen; and other authors say, it was sweeter than honey itself, with no farther account; whence it seems rather to have been used as a delicacy than as a medicine. See the articles TERENJABIN and MANNA *Persicum*.

MELAMPYRUM, *Cow-wheat*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the personated kind, consisting of one leaf, and divided into two lips, the upper of which is hooded, and the lower usually whole, not divided into any segments. The pistil arises from the cup of the flower, and is fixed to its hinder part in the manner of a nail, and finally ripening into a roundish capsule, divided into two cells, containing grains like those of wheat. *Tourn.* Inst. p. 173.

The species of *Melampyrum*, enumerated by Mr. Tournefort, are these: 1. The purple-flower'd *Melampyrum*. 2. The broad yellow-leav'd *Melampyrum*. 3. The purple and white flower'd crested *Melampyrum*. The plant called the smallest yellow *Melampyrum* by Caspar Bauhine, has no right to that name, being truly a species of the ranunculus.

MELAN *Pharmacon*, a word used by Hippocrates, and by some supposed to mean common writing ink: He orders this to be poured upon the cranium, in case of a fissure, in order to discover how far it has penetrated. Galen seems to refer to this, in some places, and mentions his having treated of it in his book of ulcers; but as no such medicine is found prescribed there, it is probably one of the lost compositions of the antients. In the spurious editions of Hippocrates, his book treating of the diseases of women, there is a black medicine ordered to be made of the squammæ and flos æris.

MELAENATOS, the *black eagle*, a species called also *aquila valeria* by some authors. It is a small eagle, of twice the bigness of a crow. Its jaws and eyebrows are destitute of feathers, and look reddish; its head, neck, and breast, are black, and in the middle of its back he has a large triangular spot, of a pale brownish red, with something of whiteness intermixed. His rump is a reddish brown, and his wings variegated with black, white, and grey. His beak is not large, black at the end, the skin covering the nostrils red, and the iris of his eye hazel-colour'd. His legs are feathered a little below the knee, and below that are red; and the claws very sharp. *Willughby*'s Ornithology, p. 30.

MELANCHOLY, *Melancholia*, (*Cycl.*) in medicine, the name of a disease which consists in the perturbation or injury of the imagination, which prevents it from forming a regular and determinate idea of things, as at other times; so that its due operations are interrupted, and often second ideas, having no connection with the first, crowd in, and are succeeded by actions no way analogous to that first idea, and therefore appearing irrational.

Authors distinguish *Melancholy* into three kinds; the sad, the merry, and the mixt, partaking of the nature ofboth; but in all these the cause is the same, and the difference is only owing to the temperament and habit of the patient.

This distemper has, however, its more essential differences, in regard to the causes from which it is produced. In some people, it seems wholly to depend upon a false prefiguration and judgment of things in the mind; and in this case it is usually habitual and incurable. In others it arises from injuries of the body; and in these it always is observed to bear a proportion to the injury or debility of the parts. This peculiar species is called hypochondriac *Melancholy*; and finally, in others it seems of a mixt nature; as when it has taken its first origin from distemperatures in the body, but is afterwards so encreased by mental disorders, that even after the total removal of the corporeal ones, it still remains in all its force upon the mind. This is a too common, and very unhappy case.

Signs of it. These are a perpetual anxiety of mind, without any rational cause; a distaste and dislike to every thing, even before it comes in sight, and often a weariness even of life itself. A frequent weeping for imaginary causes, or for no cause at all. Many people, in this case, seem always to want room; they are for opening all the windows they can, and for running out into the streets or fields, thinking themselves every where imprisoned; others leave their houses, and dread being taken up for capital offences, tho' never guilty of any; and, in others, these distemperatures of the mind are evidently joined with others of the body, such as palpitations of the heart, sighing very deeply, painful respiration, strictures of the tonic motions of the parts, tremblings, paleness of the countenance, and extenuation of the body. Sometimes, instead of these restrictions, there are frequent remissions of the same tonic motions, whence arise sudden flushings of the face, uncertain heats in the body, and a general lassitude and loss of strength. In most cases of this kind, there is an obstinate costiveness of the bowels, and the affections of the mind are increased by terrible watchfulness, and if the persons sleep a little, they are terrified with troublesome dreams all the while; if of sanguine habits, they are continually dreaming of blood, of battles, and of fires; and, if of phlegmatic constitutions, of water and drowning. Dreadful apprehensions happen also between sleeping and waking, and they usually awake in agonies, with violent tremblings, and difficulty of respiration. In the merry *Melancholy*, the alienations of the patient's mind are employed about chearful, and often obscene ideas; and sometimes their fancy exalts them to the state of kings and princes.

Persons subject to Melancholy. These are principally men of great learning, and of sedentary lives, hypochondriac people, and such as are troubled with disorders of the spleen; and to these are to be added women subject to hysteric complaints.

Causes of it. These are principally a spissitude of the blood, and a detension of it about the vena portæ; a bad disposition of the internal parts, as a schirrous or ulcerous constitution in them, or an actually ulcerated state. Persons who are afflicted with *Melancholy*

Melancholy from thefe caufes, are ufually fubject to very unruly paffions, and thofe of various kinds; love, fear, dejection of fpirits, defpair and anger, are often very predominant in them. A fuppreffion of the hæmorrhoidal difcharges in men, and of the menftrual ones in women, will alfo frequently throw them into this diftemper; as will alfo an over great application to ftudy, efpecially on abftrufe fubjects; a confcientious dread from paft crimes; continual difappointment in the expectations; and fometimes a timorous difpofition, brought on in infancy, by the folly of nurfes.

Prognoftics in it. That kind of *Melancholy* which is brought on by immaterial caufes alone, fuch as that arifing from too intenfe ftudy, or other imaginations or effects of the mind, is always greatly more obftinate and difficult of cure than that which depends upon material caufes, and has its origin in a diftempered ftate of the body. The hypochondriac *Melancholy* is the moft eafy of all to be cured, efpecially if the hæmorrhoidal difcharges can be brought on regularly again, yet even thefe cafes muft be taken in time, for when the *Melancholy*, even from fuch caufes, is become habitual, it will remain after the caufe is removed which gave them origin.

Method of Treatment. *Melancholy*, when it depends on immaterial caufes, requires phyfic for the mind rather than for the body, and the frequent converfation with an ingenious friend, of a calm and quiet difpofition, will go farther towards a cure than a thoufand medicines. Perfons in this ftate muft be as little thwarted or contradicted as poffible, and whips and chains are to be avoided, unlefs in cafes of the moft extreme neceffity; this is alfo a method equally neceffary in thofe cafes where habit has confirmed upon the mind that diforder, which at firft arofe merely from material caufes. But when the difeafe not only arifes, but as yet depends entirely upon material caufes, the cure is eafy, and is to be performed in the following manner: The *primæ viæ* are to be cleanfed by purges, particularly thofe made of black hellebore, and after this the patient is to be blooded in the foot, taking away about fix ounces. Then the blood is to be attemperated by giving, three or four times a day, powders compofed of purified nitre, and the common abforbents; and after a due ufe of thefe, the parts are to be reftored to their priftine tone and vigour, by the milder chalybeates; the greateft care muft alfo be taken to bring the hæmorrhoidal difcharges in men, and the menftrual ones in women, to a natural and proper ftate, and then a fufficient quantity of weak liquors drank at meals, and a moderate degree of exercife, will bring the patient ufually to an abfolute ftate of health.

Hypochondriac *Melancholy* always is more relieved by bleeding than by any other practice; and indeed all attempts of a cure are vain, if this be not firft done: Purified nitre diffolved in fmall quantities in all the patient's drink, will, in time, be found to do great things alone, as to a cure. It is the practice of fome perfons to give vomits in thefe cafes; but they often turn *Melancholy* into a true *mania*. See the article MANIA.

MELANCORYPHUS, in natural hiftory, the name of a bird, in the nefts of which, the antients tell us, they found the callais or turquoife. This feems a very ridiculous ftory, and the whole to be only founded on the refemblance of colour between that ftone and the eggs of this bird. It has been alfo difputed among authors, what was meant by the *melancoryphos* of the antients; the general opinion is, that it was that little bird which, from the blacknefs at the top of the head, we call the *black cap*. But the antients themfelves feem to have meant a fomewhat larger bird by it; for they tell us, that the ficedula, at a certain time of the year, changed colour, and became the *Melancoryphos*, or black crown. There is no great foundation for fuch an opinion as this, but it may, however, ferve to fhew, that thefe two birds were much of a fize.

MELANOCERASUS, a name given by fome botanical authors to the *folanum lethale*, or *bella donna*, a poifonous fort of nightfhade, with a beautiful berry refembling a large black cherry. *Pluk.* Almag. p. 352.

MELANOPIPER, in the materia medica, a name given by fome writers to the common black pepper. *Mont.* Exot. p. 9.

MELANTERIA, in natural hiftory, the name of a foffile fubftance, much talked of by the antient writers in medicine, and fuppofed by moft of the moderns to have been loft among the later ages. This, however, is an erroneous opinion, for it is really produced at this time in many parts of the world; though its refemblance to fome of the other foffils, in its external appearance, has made it almoft univerfally overlooked by the writers on thefe fubjects. It is, in its moft perfect ftate, a very beautiful fubftance, of a clofe, even, and regular texture, moderately heavy, and of a very beautiful yellow, like that of the fineft gold. It is, in this ftate, found in loofe irregular lumps, never very large, being ufually only from an ounce to two ounces in weight, and of a fmooth, even, and polifhed furface. This is the cafe when it is pure and folid, and it is then alfo of as bright and fine a colour on the outfide as within. *Hill's* Hift. of Foff. p. 607.

This is a ftate, however, in which it is very rarely found; we ufually meet with it either in the form of a downy efflorefcence on various fpecies of vitriolic minerals, particularly on the common marcafites and pyritæ; or elfe in loofe, fhattery, and friable maffes, of rough furfaces, of a fpongy texture, and of a coarfe dufky yellow; in either of thefe ftates, however, it fo much refembles a more or lefs pure native fulphur, that it is generally miftaken for that body. It makes no effervefcence with acid menftruums, and when put into the fire, is found not to be inflammable, but calcines firft to a whitifh, and finally to a ftrong red colour.

Water diffolves a part of its fubftance, and this may again be procured feparate from the liquor, by evaporation and cryftallization, and then it appears in form of rhomboidal bluifh green cryftals.

It is found in the mines of fome parts of the harts foreft in Germany, and is often met with on the fides of hills in many parts of the Eaft Indies, and in America; it is ufually miftaken in all thefe places for a native fulphur. Id. ibid.

MELANTZANA, in botany, a name given by many authors to the mad apple, called more ufually *Melongena*. See the article MELONGENA.

MELANURUS, in zoology, the name of a fifh caught in the Mediterranean, and fometimes, though rarely, in the Britifh feas; and called by fome writers, *occulata* and *occhiata*.

It is of an oblong and rounded body, and its back very little prominent, and of a bluifh black. Its fides are of a filvery white, but are variegated with dufky tranfverfe ftreaks. Its eyes are remarkably large, and their iris of a fine fhining yellow. Its mouth is moderately large, and its fore teeth broad, its hinder ones narrow, flender, and fharp. It has only one back fin, the anterior rays or nerves of which are prickly, but the hinder ones foft and inoffenfive. Its fcales are moderately large, and its tail is very remarkably forked. It feldom exceeds five or fix inches in length: And its tail has a remarkable black fpot in it, whence it has its name, as it has that of *occulata*, from the largenefs of its eyes. *Gefner*, de Pifc. p. 638. *Aldrovand.* de Pifc. l. 1. p. 63.

MELAONES, a word ufed by certain authors for a black kind of worm found in meadows, in the month of May, which, when bruifed, emit an agreeable fmell. Some alfo have called a fmall fpecies of beetle by the fame name.

MELASMA, a fugillation, or black mark, from a bruife.

MELASSES. See the article MOLASSES, *Cycl.* and *Suppl.*

MELASTOMA, in botany, the name of a genus of plants, called by Burman, *acinodendron*. The characters are thefe: The perianthium confifts of one leaf, and is obtufe and permanent; it is inflated in the middle, and fcarce at all divided at the edge. The flower confifts of five roundifh petals, inferted near the rim of the cup. The ftamina are ten filaments, fhort, and inferted into the cup. The antheræ are long and erect, but fomewhat crooked. The germen of the piftil is roundifh, and placed under the cup. The ftyle is crooked and emarginated. The fruit is a berry containing five cells; it is of a roundifh figure, but crowned with a cylindric rim, and furrounded by the cup. The feeds are numerous and fmall. *Linnæi* Gen. Pl. p. 190. *Burman.* Thefaur. Zeyl. p. 363. Hort. Malab. vol. 4. p. 42.

MELCHITES, a name of reproach given to the orthodox, who afferted and maintained the canons of the council of Chalcedon. It was given to the catholics by the heretics, and not by the catholics to the heretics, as mentioned in the Cyclopædia. See the article MELCHITES, *Cycl.*

The word is derived from the Hebrew *melech*, a king or prince, and fignifies the fame as royalifts, or thofe who were of the emperor's religion. For the fame reafon the emperor Juftinian had the epithet *Chalcedonenfis* given him. *Hofm.* Lex. in voc.

MELDFEE, in our old writers, a recompence due and given to him that made the difcovery of any breach of penal laws, committed by another perfon, called the promoters or informers fee. *Leg.* Inæ. c. 20. *Blount.*

The word is Saxon from *meldfeoh.*

MELEAGRIS, the *Turkey*. In the Linnæan fyftem of zoology, this makes a diftinct genus of birds, of the order of the gallinæ; the diftinguifhing characters are, that it has four toes on each foot, a flefhy papillofe creft on its forehead, and long naked wattles. *Linnæi* Syftem. Natur. p. 48.

MELECH, a word ufed by fome of the chemical writers to exprefs falt. See the article SALT.

MELECHIL, a word fometimes ufed as the name of the gum *bdellium*, and fometimes as that of the fruit of a tree of the palm kind, much ufed by the antients as a cordial and reftorative. The word *mokel* has the fame double fenfe, and both are, by the more accurate writers, determined in their meaning by the epithets annexed to them, the gum *bdellium* being called *Molechil*, or *mokel judaicum*, and the fruit *mokel mechenfe*; yet the confequence of even this has been more confufion; for the later writers fuppofed, that the fruit was not produced by a palm-tree, but by the fame tree which produced the gum. See the articles MOKEL and BDELLIUM.

MELEGEION, a word ufed by fome writers in medicine to exprefs a fætid matter, of the confiftence of honey, difcharged from old ulcers.

MELES, the *Badger*, in the Linnæan fyftem of zoology, makes a diftinct genus of animals, among which the author includes the civet cat, as the creature which affords us the

perfume of that name is usually called. The characters of this genus are, that the animals of it have eight paps, two on the breast, and six on the belly, with feet with five toes on each, on the hinder as well as the fore ones. The author distinguishes the common *Badger* by his having the claws of his fore feet much longer than those of the hinder ones; and the civet animal by its having all its claws of the same length. *Linnæi* System. Natur. p. 37. See the article TAXUS.

MELET, in zoology, a name used by some for a small transparent sea fish, called by authors, *hepsetus* and *anguilla*, and by some, *atherina*. *Willughby*'s Hist. Pisc. p. 210. See the article HEPSETUS.

MELIA, Μελία, of the Greek writers, the name of a vegetable that often occurs in the Greek naturalists, and which has so many significations, that it is not easy to understand the authors, without being well acquainted with them. All late writers have perplexed the world by miscalling things, and thence rendering names synonimous and confused, which were at first clear and distinct; but the confusion of the senses of the word *Melia* is as old as the earliest writers we are acquainted with: Theophrastus complains of it in his time.

The most common use of the word is for the *fraxinus*, or ash-tree. The antients used to make the handles of their spears and darts of this, and therefore they sometimes called them *Melia*. This word was also used as the name of a seed, called also by some, *meline*. This was of the nature of panic, and by some confounded with the panic. Suidas mentions this as different from the panic; but Diocles seems to have made them the same seed. Pliny has translated the passage from Diocles, and, by an unaccountable error, has called the plant *melfrugum*, and says, that it has the same virtues with millet.

MELIA, in botany, the name by which Linnæus calls the *azedarach*. See the article AZEDARACH.

MELIA *Terra*, in natural history, a name given by some authors to the *melinum*, or white earth of the island of Melos, used among the antients in painting; but in the works of Dioscorides and Galen signifying a substance of a very different kind; the *melinum* of the painters having been a *Marle* (see the article MELINUM) and the *Melia Terra* of the physicians a tripela. The confusion between these two substances, arises from the same source with that of a vast number of others in the materia medica, and natural history of the antients, things having, though ever so different in their nature and structure, been at different times called by the same name, merely because brought from the same place.

The *Terra Melia* of Dioscorides, and the antient physicians, is a dry, loose, and harsh earth, found in masses of different size, and lodged among the looser strata of other matter, never making a stratum of itself. It is very firm and hard, of a pale greyish white or light ash colour, very heavy, of a loose, open, and spungy texture, and of a rough, uneven, and dusty surface. It adheres slightly to the tongue, and does not stain the hands, but leaves a dust after the handling, which is so harsh as to make a grating noise, when the fingers are afterwards rubbed together. It makes no effervescence with acids. It is found in all the islands of the Archipelago, and was used by the antients for the same purposes that the pumice was. *Hill*'s Hist. of Foss. p. 68.

MELIANTHUS, in botany, the name of a genus of plants, the characters of which are these: The flower is of the polypetalous anomalous kind, being composed of four leaves, sometimes expanded into the shape of a fan, and sometimes contracted into that of a cone. The cup is unequally divided into several segments, and from it arises a pistil, which afterwards becomes a square fruit, inflated in the manner of a bladder, and divided into four cells, which contain roundish seeds. *Tourn.* Inst. p. 430.

The species of *Melianthus*, enumerated by Mr. Tournefort, are these: 1. The African *Melianthus*, called the great spiked African pimpernel. 2. The smaller procumbent African pimpernel-leav'd *Melianthus*. And 3. The least American *Melianthus*. See Tab. 1. of Botany, Class 11.

MELICA, in botany, a name given by some authors to the plant which produces the *sorghum*, or Indian millet. *Park.* Theatr. 1136.

MELICA, a word used by the antients as the name of a food of a refrigerating and moistening quality. It seems to have been a kind of *oxygala*; for Galen, where he directs persons of a hot habit to use a refrigerating diet, among other aliments of that kind, directs the eating of *Melica*, which, he says, is prepared of milk. Constantine, in his book of Agriculture, mentions *Melica*, and says it was made by pouring milk into an earthen vessel, first well impregnated with boiling hot vinegar, by means of which there was a separation of the milk into whey and curd.

MELICERIOLA, a diminutive of the word *Meliceris*, a small encysted tumour. See the article MELICERIS, *Cycl.*

MELICHLORUM, in natural history, a name given by some of the antient writers to a species of jasper, of a greenish yellow, usually found variegated with other colours.

MELILOTUS, *Melilot*, in botany, the name of a genus of plants, the characters of which are these: The flower is of papilionaceous kind. The pistil arises from the cup, and finally becomes a naked capsule or pod, not inclosed in the cup in the manner of those of the trefoil, and containing one or two roundish seeds. The leaves grow three on every stalk. *Tourn.* Inst. p. 406.

The species of *Melilot*, enumerated by Mr. Tournefort, are these: 1. The common or German *Melilot*. 2. The common *Melilot*, with white flowers. 3. The *Melilot* with long and sharp pods. 4. The tall shrubby white-flower'd *Melilot*. 5. The tall shrubby yellow-flower'd *Melilot*. 6. The greater *Melilot*, with reflected pods. 7. The little creeping *Melilot*, with reflected pods. 8. The Italian *Melilot* with roundish seed-vessels. 9. The narrow-leav'd creeping *Melilot*, with roundish seed-vessels. 10. The little yellow *Melilot*, with small flowers, and seed-vessels arranged in thick spikes. 11. The little yellow-flower'd *Melilot*, with larger flowers and seed-vessels, dispos'd in longer and looser spikes, and with narrower leaves, each having a black spot near the pedicle. 12. The procumbent *Melilot*, with longish rugged leaves, and short spikes of flowers. 13. The *Melilot* with kidney-shaped seed-vessels collected into heads, called the yellow-field trefoil, with numerous seeds. 14. The great sweet-scented *Melilot*, with violet-colour'd flowers. 15. The cretic *Melilot*, with very large fruit. *Tourn.* Inst. p. 408.

In the acts of the academy of Petersburgh, we have a description and draught of a new species of *Melilot* growing from seeds gathered in Siberia. It is there called *Melilotus siliqua membranacea compressa*. See Tom. 8. p. 229. seq.

Melilot is scarce ever given internally, but used externally; it is a great emollient, resolvent, and digestive. It is a good ingredient in cataplasms and fomentations of this intention. The flowers are recommended by some in infusion, in the manner of those of chamomile, as a remedy for the *fluor albus*.

MELINTZANIUM, in botany, a name given by the later Greek writers to the plant called *strychnus* by the earlier writers of that nation. Theophrastus, and all the old Greeks, use the word *strychnus*, and say there are three kinds, two of which are poisonous, and the other not. The first causing madness, the second causing sleep, and the third bearing an esculent fruit. This last is the plant we call *pomum amoris*, the fruit of which is at this time eaten by many people.

It is not agreed by the late Greek writers whether this word *Melintzanion* shall stand for some one kind of the nightshade, or for them all: If they borrowed it from the Italian *melanzana*, which seems probable enough, then it can only stand for that kind, not for the whole class of nightshade; but we find some of them using it for the whole number of the nightshades, poisonous and not poisonous, and making it only a synonym to *strychnus*, others using it as the name of the fruit of the *pomum amoris*, or love-apple, and others for the fruit of the male mandrake, which is also esculent, and which, Dioscorides tells us, was eaten by the peasants of his time, but that it made them sleepy, if eaten in too large quantities.

The Arabian physicians use the word *bedengian* in the same sense, sometimes applying it to the love-apples alone, and sometimes to the whole family of the nightshades; and it is probable enough, that both the Italians and later Greeks copied their name *melanzana* and *melantzanion*, from *melongena*. Myrepsus has the words *melentzanon* and *agriomelentzanon*, that is, a wild kind of the *pomum amoris*, very frequent, and commends the seeds, and other parts of the plant, in fevers, and many other diseases. Fuchsius confesses that he does not know what to make of the word; but it is wonderful that the similitude of sound between this and the *melanzana* and *melongena* did not lead him to the knowledge of what it was, as he was acquainted with those words.

MELINUM, in natural history, the name of an earth, famous in the earliest ages of painting, being the only white of the great painters of antiquity; and, according to Pliny's account, one of the three colours with which alone they performed all their works.

It is a fine white marly earth, of a very compact texture, yet remarkably light; a sort of texture which must render any earth fit for the painter's use, that is of a proper colour. It is frequently found forming a stratum in the earth, lying immediately under the vegetable mould. It is of a very smooth, but not glossy surface, is very soft to the touch, adheres firmly to the tongue, is easily broken between the fingers, and stains the skin in handling. It melts readily in the mouth, and is perfectly fine, leaving not the least grittyness between the teeth. Thrown into water, it makes a great bubbling and loud hissing noise, and moulders away into a fine powder. It does not ferment with acids, and suffers no change in the fire. These are the characters by which the *Melinum* of the antients is distinguished from all the other white earths. It is still found in the same place from whence the painters of old had it, which is that from whence it has its name, the island of Milo, called Melos by the Greeks, and is common in most of the adjacent islands. It has been of late tried here as a paint, and is found not to make so bright a white as the other substances now in use among the painters, but seems not liable, like them, to turn yellow; and if so, would be worth the consideration of persons in the colour trade, especially as it may be had in any quantities for carriage. *Hill*'s Hist. of Fossils, p. 43.

MELINUS *Color*, Μήλινον χρῶμα, in antiquity, a colour often mentioned in speaking of the habits of players. It was a reddish yellow, or the colour of ripe apples, in Greek called μῆλα, and their colour μηλοειδὲς χρῶμα. *Hofm.* Lex. in voc.

MELISSA, *Balm*, or *Baum*, in botany, the name of a genus of plants, the characters of which are these: The flower is composed of one leaf, and is of the labiated kind. The upper lip is erect, and of a roundish figure, but bifid at the end. The lower lip is divided into three segments. The pistil arises from the cup, and is fixed, in the manner of a nail, into the hinder part of the flower, and surrounded with four embryos, which afterwards become so many roundish seeds, ripening in an open capsule, which was the cup of the flower. The flowers of *Baum* always grow in the alæ of the leaves, but they do not always surround the stalks like those of the sideritis. *Tourn.* Inst. p. 193.

The species of *Baum*, enumerated by Mr. Tournefort, are these: 1. The common garden *Baum*. 2. The hairy strong smelling Roman *Baum*. 3. The low broad-leav'd *Baum*, with a large purple flower. 4. The low broad-leav'd *Baum*, with a very large white flower. 5. The low narrow-leav'd *Baum*, with a very large flower. 6. The short-stalk'd, plantain-leav'd Pyrenean *Baum*.

Baum is greatly esteemed among the common people, as good in disorders of the head and stomach; but is less regarded in the shops. It is most conveniently taken by way of infusion, like tea; and the green herb, contrary to the general rule in regard to other plants, is much better than the dry. See the article BALM.

Hoffman has contrived a process for the obtaining the virtues of this plant, which affords its principles better than any other, and gives two medicines to the physician, unknown before, but of great value.

This method might be pursued with the same success in other cases, and many plants, not sufficiently esteemed at present, might thus afford useful preparations.

He took a large quantity of the leaves of *Baum*, fresh picked from the stalks, and filling a glass vessel more than half full, with them, fixing the stopper carefully in, he put the vessel into a dung-hill, where he let it remain three months: At the end of this time he took it out, and found the whole reduced to a kind of pultice. This being distilled in a retort, yielded first an empyreumatic liquor, but afterwards, when the fire was increased, a black and stinking oil came over, in form of thin laminæ, spreading itself over the surface of the liquor. There remained at the bottom of the retort a black and burnt mass, resembling a coal, which, being thrown on burning charcoal, had very much the smell of the common tobacco.

In this first distillation no volatile salt appeared, but the empyreumatic liquor being examined, was found very sharp and acrid on the tongue, and of a sharp and pungent smell. Spirit of vitriol being mixed with it, it afforded no effervescence; but on the mixing it with spirit of hartshorn, spirit of urine, or the like, a small ebullition always was produced, though it lasted but a few moments.

This liquor, rectified by a second distillation, affords the volatile salt of *Baum*, which is a fine white and pellucid substance, adhering to the neck of the glass, in form of fine white and striated crystal, and a yellow ætherial oil, of a very penetrating smell, and sharp taste, becomes separated by the same rectification. These are both found to be very great medicines, the salt as a sudorific, and the oil as a high cordial, a carminative, and a deobstruent. *Hoffman*, Act. Laborat. Chem.

MELITENSIS *Terra*, *Earth of Malta*, in the materia medica, an earth of which there are two very different kinds, the one of the genus of the boles, the other of the marles. The latter is that known by medicinal authors under this name; the former is the Malta earth now in use: But both being brought from the same place, are confusedly called by the same name.

The Maltese bole, which is what we use now, is a fine earth, of a close compact texture, and very heavy; when dug, it is of a very pure white, but it is apt to contract a yellowness in drying, and become of a cream colour. It is of a very smooth and shining surface, scarce at all stains the skin in handling, adheres strongly to the tongue, and melts into a butterlike substance in the mouth. It makes no effervescence with aqua fortis, or any other acid menstruum, and suffers no change of colour in the fire. *Hill's* Hist. of Fossils, p. 4.

The Maltese marle, which is the *Terra Melitensis* of medicinal authors, is a loose, crumbly, and very light earth, of an unequal and irregular texture, and when exposed to the weather, soon falls into fine soft powder; but when preserved and dried, it becomes a loose light mass, of a dirty white colour, with a greyish cast; it is rough to the touch, adheres firmly to the tongue, is very easily crumbled to powder between the fingers, and stains the hands. Thrown into water it swells, and afterwards moulders away into a fine powder. It ferments very violently with acid menstruums.

Both kinds are found in great abundance in the island of Malta, and the latter has been much esteemed as a remedy against the bites of venomous animals, but with how much justice we cannot say. The other has supplied its place in the German shops; and is used there as a cordial, a sudorific, and astringent. *Hill's* Hist. of Fossils, p. 37.

MELITITES, in natural history, an indurated clay, of a yellowish colour, but in many respects approaching to the nature of the morochthus or common French chalk.

It has its name from the Greek μέλι, honey, according to Dioscorides, from the sweet taste of the liquor it dissolved into on rubbing with water; and probably it might be also so called from its colour, which does not ill resemble that of honey.

The antients used it much in medicine; they applied it externally in ulcers, and gave it inwardly as a soporific to people who were to suffer pain, supposing it would make them less sensible of it. It is at present very common in Italy, and probably in many other places, but is not known or regarded. It is a very smooth substance, nearly as hard as the *morochthus*, of a very compact texture, and of great weight; of a fine even and glossy surface, very smooth and soft to the touch, and in colour of a greyish yellow. It does not at all adhere to the tongue, nor stain the fingers in handling; but drawn along a rough surface, leaves a fine slender white line; and shaved into very thin pieces, has some faint degree of transparence. It dissolves, on rubbing in water, into a yellow thick liquor like cream, which has a luscious or sweetish taste. It does not ferment with acids, and burns to a pure white. The sweet taste of this is common, in some degree, to the *steatites*, *morochthus*, and all the indurated clays, as are also their semi-transparence in thin pieces, and all their other properties. *Hill's* Hist. of Fossils, p. 24.

MELITITES *Lapis*, a name given by some authors to some of the rounder species of *echinitæ*, from their resembling an apple in their shape.

MELITTOMA, a word used by the antients to express a sort of sweet-meat, or confection, made with pleasant ingredients mixed in honey.

MELLAGO, a word used by medicinal writers to express any medicine that has the consistence and sweet taste of honey. It is often applied to the rob, or inspissated juice of fruits, mixed with sugar in the making.

MELLE, or MULLI. The Peruvians, by gently rubbing the fruit of this tree between their hands in warm water, deprive it of all its sweetness; after which they strain the liquor, and leaving it a few days to subside, it becomes a very transparent drink, and by boiling becomes an excellent kind of honey. Garcil. ap. *Boyle's* Works abr. vol. 1. p. 53.

MELLEGUETTA, in the materia medica, a name used by some authors for the great cardamom, commonly called grain of paradise. *J. Bauhin.* vol. 2. p. 204. *Jons.* Dendr. p. 114.

MELLEUM *Marmor*, in natural history, the name of a plain yellow marble, resembling honey or pure Venice turpentine in colour, and thence called by Cæsalpinus, *Marmor specie Mellis aut Terebinthinæ*. It is a very beautiful marble, tho' but of one plain colour, and 'tis a wonder it is not more imported into England. It is of a very agreeable colour, and is considerably hard, and capable of a very elegant polish. It is dug in many parts of Italy, and is greatly esteemed there. It never has any veins. *Hill's* Hist. of Fossils, p. 464.

MELLINE, in botany, a name given by many of the antient writers to the garden plant we call *Baum*. It had the name *Melline* from its yielding honey to the bees.

It has many other names, derived from the same source; such as *apiastrum*, from *apis* the bee, *meliphyllum*, the honey-leaf, and from this, *melissophyllum*. Many also are of opinion, that the *amello* of Virgil is the same plant. He describes it as having a gold-colour'd flower, and purple leaves at the bottom; this they explain by observing, that in *Baum* the stamina of the flowers which stand out, and are the most conspicuous parts, are yellow, and the leaves of the calyx or flower-cup are purple: These, they say, are what Virgil means by the leaves at the bottom, not the common leaves of the plant growing from the root, which are not to be supposed purple in any plant.

MELLISODIUM, a word used by some chemical writers to express burnt lead.

MELLITA, in natural history, the name of a genus of the *echini marini*, of the general class of the placentæ. The characters of the *Mellita* are, that they are plain and flatted shells, with their edges arched and waved, and have on their superficies two or more oblong apertures, which reach to the base. Of this genus, there are two known species; 1. A smooth one with a circular vertex. 2. A scutellated kind, resembling the shell of the tortoise, and with a pentagonal vertex. *Klein's* Echin. p. 30. See Tab. of Testaceous Animals, N°. 9.

MELO, the *Melon*, in botany. See the article MELON.

MELOCACTUS, the *Melon Thistle*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the monopetalous kind, and is tubulated at the bottom, and expanded into the form of a bell at the top, with serrated edges; this stands upon a cup, which finally becomes a soft fleshy fruit, of the shape of an olive, which contains a small seed. In many of the species, however, the fruit is collected into an elegeant head.

The species of *Melocactus*, enumerated by Mr. Tournefort, are these: 1. The common East Indian *Melocactus*. 2. The purple

purple *Melocactus*, with crooked fpires. 3. The fquare creeping American *Melocactus*, with white flowers and fcarlet fruit. 4. The creeping trigonal American *Melocactus*, with white flowers. 5. The fquare tree American *Melocactus*, with white flowers. 6. The arborefcent American *Melocactus*, with ftriated very prickly leaves, white flowers, and yellow tuberofe fruit. 7. The very prickly American *Melocactus*, with feveral globules joined together in the manner of the opuntia. 8. The fmall lanuginous tuberous American *Melocactus*. 9. The fingle-ftalked American *Melocactus*, with white flowers, and blackifh purple fruit. 10. The tuberous purple American *Melocactus*, with very ftrong and fharp prickles. 11. The trigonal undulated American *Melocactus*, with very robuft prickles, and white flowers and greenifh fruit. 12. The trigonal American *Melocactus*, with fhort prickles and white flowers, and fcarlet fruit. 13. The creeping pentangular American *Melocactus*, with white flowers and red fruit. *Tourn*. Inft. p. 653.

MELOCARPUS, a word ufed by fome of the old authors to exprefs the fruit of the *ariftolochia*, or *birthwort*, ufed in fome external applications. See the article ARISTOLOCHIA.

MELOLANTHUS, the name of a peculiar fort of beetle, which is found in all parts of England, and in many other countries among trees and hedges. The French call them *hanneton*, and we *cock-chafers*, *dorrs*, and by many other names. The name *melolanthus* is as old as Ariftotle, and is given this creature from its feeding on the bloffoms of the crab or wild apple. We have, of late years, had great damages done by the grubs of thefe beetles working under ground; but in Ireland they have been ufed to come in fwarms, in certain years, in the beetle ftate, and have been fo terrible to this country, that the people have called them locufts.

The firft time they are remembered by authors to have appeared in this vaft abundance, in this country, was in the year 1688. They then appeared in the fouth-weft part of the county of Galway; they appeared firft upon the coaft, and were brought by a fouth-weft wind, a wind fo common there, that it may almoft be called, the trade wind of Ireland; from the coaft they foon fpread over the inland parts of the county, and were feen every where in fuch numbers, as were fcarce to be conceived. They never ftirred in the day-time, but were feen covering the leaves and branches of trees and hedges, and in many places hanging down in prodigious clufters on one another's backs, in the manner of bees when they fwarm. As foon as the fun fet, they ufed to leave the hedges, &c. and take wing, gathering into bodies, and making a humming confufed noife like that of drums at a diftance. They fometimes formed bodies together, that darkened the air for three or more miles fquare. They flew fo low fometimes, that it was fcarce poffible for a perfon, going along, to make his way through them; and by ftriking againft the faces and necks of women and children, they did much mifchief, every one leaving a mark behind it; and thofe of this fex or age, who had been among them, came home all over bruifes.

This, however, was little to the mifchief they did the fields; for though the middle of the fummer was the feafon in which they came, they had, in a few days, eaten up all the leaves of the trees fo compleatly, that they all looked as bare as in the depth of winter. The noife they made, while eating in vaft numbers together, was like that of fawing timber. The gardens fared no better than the hedges, for they eat up leaves, young ftalks, and fruit, and every thing that was green and foft there, and left only a parcel of naked fticks behind them. Many of the trees, thus ftripped, wholly perifhed. Phil. Tranf. Nº. 234.

MELOMELI, a word ufed by the antients to exprefs honey impregnated with quinces.

MELON, *Melo*, in botany, makes a diftinct genus of plants, the characters of which are thefe: The flowers confift only of one leaf each, and are wide at the mouth, and divided into feveral fegments, wholly refembling the flowers of cucumbers. Of thefe alfo fome are male or fteril flowers, having no embryo fruit; others are fruitful or female flowers, having an embryo which ripens into a large fruit of an oval figure, fometimes fmooth, fometimes rough, divided into three cells, and containing oblong feeds; each of thefe cells feems alfo divided into two.

The fpecies of *Melon*, enumerated by Mr. Tournefort, are thefe: 1. The common *Melon*, with Dodonæus calls the *cucumis* of Galen. 2. The great fmooth green *Melon*, with fmaller feeds. 3. The Spanifh *Melon*. 4. The fmall round *Melon*, called the fugar *Melon*, and round mufk *Melon*. 5. The turbinated *Melon*. 6. The reticular *Melon* of John Bauhine. 7. The little Egyptian *Melon*. *Tourn*. Inft. p. 104.

Melon feed is cooling and diuretic, and has the fame virtues with the other cold feeds, as they are called. See the article GOURD.

The proper management and culture of *Melons* is this: The feeds fhould be procured from good *Melons*, produced in fome diftant garden; for if fowed on the place where it was raifed and ripened, it is very apt to degenerate. This feed fhould be kept three years before it is fowed, and it fhould be fowed at two feafons. The firft for the early crop, to be raifed under frames, fhould be fown in January or the beginning of February; the fecond, to be raifed under bell or hand-glaffes, is to be fowed in *March*, and this is the fowing which produces the general crop of *Melons*, which ripen in July and Auguft.

About a week before the time of fowing the feed, fome dung fhould be prepared in a heap with the litter, or fome coal-afhes, and the fame methods ufed as in the early cucumbers, for the firft crop; but for the fecond, which is of more general ufe, the fowing may be on the upper fides of the hot-beds that were for the early *Melons* or cucumbers, or on a frefh moderate hot-bed. When the young plants are come up, they muft be removed to another hot-bed, and covered with hand-glaffes, and watered and fhaded till they have taken root; and after this they muft have as much air and fun as the feafon will permit, and their ftalks fhould be earthed up as they grow, which will vaftly ftrengthen them.

In the beginning of April the plants will begin to fhew their rough leaves, a parcel of dung is then to be prepared with the litter and coal-afhes. The common quantity is a load to five holes; a trench muft then be dug, which fhould be ten inches deep, if the foil be dry, but only three if it be wet. The dung muft be evenly laid in this, and heaped up to three foot high. Then the places intended for the holes muft be marked out, at each of which muft be laid a bafket-full of light rich earth, thrufting a ftick of two foot long into the middle. Then cover the dung all over with the earth which was dug up out of the trench, laying it fmooth, and about three inches thick; then the glaffes are to be placed clofe down over the place where each of the fticks is, and in two days the earth will be warm enough to receive the feedling plants. The fticks are now to be taken out, and the earth formed in the places into a hollow like a bafon, that it may retain the water which is given to the plants. The plants are then to be taken up, and two ftrong and thriving ones put into each of thefe holes, which muft be watered and fhaded till they have taken root. The plants having taken root, and thruft out a fourth leaf, the top of each of them fhould be pulled off, in order to force out fhoots from the bottom, and as the weather becomes warmer, the glaffes muft be raifed with ftones on the fouth fide, to give them air, and about twice a week they fhould have a little water.

About the middle of May the ftalks of the plants will begin to prefs upon the glaffes on every fide, and the glaffes are then to be raifed up on bricks, to give them room to run out; and they fhould be pegged down with forked fticks, and turned into a proper direction for their running, fo that they may be out of the way of tangling one with another: They fhould now, if the weather be fevere, be fheltered with mats in the night, and watered gently at times. When the ftalks of the plants are grown to the edges of the bed, the earth muft be raifed with old dung buried under it, till it be upon a level with the beds, for two foot wide on each fide. The branches are here to be trained in a proper courfe, and the glaffes are to be left over the roots of the plants, and after this, what water is given them is to be fprinkled all over the plants.

When the fruit begins to appear, the waterings muft be very gentle on the plants; but it will be proper to foak the earth well with large quantities of water about the beds, which will fpread a moifture even to the roots of the plants; from this time the plants fhould be gently watered twice a week, and that always in the evening. When the *Melons* are grown of the fize of a tennis ball, a piece of tile fhould be laid under each to keep them from the ground. As they afterwards approach to ripenefs, they fhould be turned feveral times, that they may ripen equally on every fide; and if the weather be not very favourable, they fhould be covered with glaffes. If the *Melon* is defigned to be eaten as foon as cut, it fhould be fuffered to remain on the plant till it changes pretty yellow, and the ftalk begins to feparate from the fruit; but if it be to be kept two or three days after cutting, it muft always be cut proportionably ealier.

It is a practice with many to take off the leaves about the fruit, that it may have more fun; but it is wrong, and the fruit is always the worfe tafted for it, and the fkin is hard and tough. *Miller*'s Gardener's Dict.

Whenever a *Melon* appears well knit on a branch, it is proper to cut off all the reft of the branch beyond it, that the fruit may receive all the nourifhment that would have been conveyed into the whole branch; only it muft be obferved, that a fufficiency of leaves, of the neighbouring branches, be left or brought over it, to fhade it from the exceffive heat of the fun in the drought and heat of the day.

There is ufually required the fpace of forty days, from the time of a *Melon*'s firft knitting on the branch, to its being perfectly ripe: But in cold feafons they are fometimes longer.

In order to fave good feed for the next year, no other feeds are to be taken out than thofe which have lain in that part of the fruit which is next the fun, and thefe fhould be taken out at the time of the eating the *Melon*, and immediately wiped dry with a cloth, and laid up in a dry place.

Melons fhould not be eaten till they have been gathered twenty-four hours; they fhould, in the mean time, be laid in a cool but dry place. The proper time of gathering them is a thing of great confequence to the eating them in perfection; they generally difcover the proper degree of ripenefs

 for

for gathering, by their smell, and by the splitting of their tail. The common kinds shew the approaching ripeness by a yellowness coming on in some part: This begins in one place, and spreads, by degrees, over a great part of the fruit. It is to be observed that twenty-four hours after the time of the first appearance of a yellowness in some part, is the exact season for the gathering of these *Melons*. A *Melon* that ripens too fast is never good; such a ripeness is unnatural, and proceeds only from the poorness or sickness of the root, which makes it turn thus suddenly. Phil. Transf. N°. 46.

When a *Melon* is perfectly fine, it is full, without any vacuity: This is known by knocking upon it, and when cut, the flesh must be dry, no water running out, only a little dew, which is to be of a fine red colour. Large *Melons* are not to be coveted, but firm and well flavour'd ones. Our Gardeners, who raise *Melons* for sale, sow the seeds of the large rather than the good kinds, and they encrease the size of these by much watering the roots, but this spoils the taste. Some of the French raise at this time particularly fine *Melons*, by a method kept as a secret, but which we find, on a strict enquiry, is no other than the ingenious Mr. Quintiny's, of that nation, published near eighty years ago in our Philosophical Transactions.

The *Melons*, particularly proper to be treated in this manner, are those which have a thin and somewhat embroidered skin, not divided by ribs, and have a red pulp, dry and melting on the tongue, not mealy, and of a high flavour. These are what succeed in the following method, and are greatly improved in size and flavour by it.

When the seeds of this *Melon* are placed in the ground, the first thing that appears is a pair of seminal leaves, or ears, as the Gardeners call them. Between these two leaves there shoots, some days after, a leaf, called the first leaf, or knot; and out of the same place, after some days more, there shoots another leaf, called the second knot. Out of the midst of this stalk of the second knot, there shoots a third knot: This third knot must be cut off at its insertion, without hurting the branch of the second knot from whence it grows. Out of this place there will grow, after this cutting, a branch, which will be what the gardeners call the first arm, and this arm will, in the same manner as the first plant, shoot out, first one, then a second, then a third knot; this third knot must be cut again as before, and thus the third knots are all along to be cut off, and arms or branches will grow up in the places of them, all the way in the same manner as the first; and it is at those arms that the *Melons* will be produced; and they will be always good, if the foot or root be well nourished in good earth, and cherished by a good hot bed and the sun. The foot of the *Melon* must never be suffered to pass into the dung, nor the earth must not be watered but moderately, when it is seen to grow too dry; but in this case, it must be moderately moistened in time, least the shoot suffer by it. Twice or three times a week is often enough to water in the driest weather, and this must always be done about sunset; and when the heat of the sun is too violent, the *Melons* must be covered with straw mats from eleven in the morning to about two in the afternoon. When it rains much, the *Melons* must also be covered, lest it hurt them by too much moisture. Phil. Transf. N°. 45.

If the root produce too many branches, the weakest are to be cut off, and only three or four left; and those which are left are to be such as have their knots closest to one another.

When the plants are removed from the seed-bed to the places where they are to stand, if they are very strong, they should be planted single, but if otherwise, two are to be set in each hole.

When they are planted single, the two branches which always grow on each side, from the base of the seed-leaves, are to be left on; but when two plants are set together, these branches are to be cut off, otherwise all the branches will be too numerous, and they will entangle and spoil one another.

When the *Melons* are knit, two of them only are to be left upon each foot, chusing those which are best placed, and next to the first and principal stalk that is to the heart of the foot. None but fair fruits are to be left, and such as have a thick and short tail; and the foot of the *Melon* must be short, well trussed, and not far distant from the ground. *Melons* of a long stem, and having the stalk of the leaf too long and slender, are never vigorous.

All the superfluous branches must be cut off from time to time, as they shoot out.

There sometimes shoots out a branch more than is here mentioned, between the two seed-leaves or ears. If this is strong and vigorous, it is to be kept on, but if weakly, it is best to take it off, for it will never bear good fruit.

MELON *Seeds*. We read of *Melon* seeds thirty-three years old, vegetating and producing a fine number of plants. Phil. Transf. N°. 475. Sect. 6. and in N°. 464. we read of *Melon* seeds 43 years old, producing fruit.

Petrified MELONS, a name given by the people who have written books of travels, &c. to certain stones found on mount Carmel. The monks who inhabit that mountain at this time, and who pretend to be the followers of Elias the prophet, tell a legendary story about these stones, which has given occasion to the name. They say, that when Elias lived on that mount, a certain Gardener passing by his cave with *Melons*, the prophet asked one of them; but the fellow replying, that they were not *Melons*, but stones that he carried, the prophet miraculously fulfilled the saying, and converted them into stones. Travellers who are fond of these stories, were usually glad to pick up one of these sacred stones as they went on; and the monks have been careful enough to gather all they could find for the better opportunity of obliging their visiters; so that though they were once very common, they are now only to be had by the favour of these people.

Breynius is the only author who has given a good account of them; he says that they are spheric or spheroidal stones, of various sizes, from that of a hen's egg to that of the largest *Melon*, or even more than that. They are generally found bedded in a very hard sand stone, of a greyish or ash colour; but they come out whole on breaking the stone, and are of a smooth surface; a greyish colour, or sometimes a brownish ferrugineous hue. When they are broken, there is always a cavity found in them, sometimes regular and even, sometimes very irregular, and generally proportioned to the bigness of the stone. This cavity is lined on all sides with minute crystals, which are very bright and pellucid, and have their points standing toward the center of the cavity. The substance of the stone itself approaches to the nature of marble, of a yellowish colour, and capable of a good polish; when wrought looking very like the Florentine marble. This is a crust of about half an inch or an inch in thickness, according to the bigness of the stone, and sometimes this is covered with a paler-coloured crust, of the thickness of a straw, which in some degree resembles the bark or rind of the fruit. These stones are truly a sort of concave natural nodules, of the nature of our hollow flints. They have had no fruit for their matrix, nor have ever any of the ribs and furrows which the *Melon* has, nor any mark of the stalk; and within they have neither the natural divisions of the *Melon*, nor any thing resembling the seeds. It is not only the want of many parts absolutely essential to the fruit supposed to be petrified, which shews that opinion to be erroneous; but the course of nature, in petrifactions in general, argues also greatly against it.

The things we meet with, in this state, are all of them such as are naturally hard, dry, and permanent, and none of the tender and succulent bodies, such as the *Melon*, and the like fleshy fruits, which must necessarily rot in the water that conveys the stony matter, before it could at all enter their pores. And the stones are certainly analogous to those concave nodules of a ferrugineous colour, in the cavities of which amethysts are produced; and to that genus of stones which Woodward calls concave crystalline balls, common in many parts of the world.

The fallacy of an extravagant opinion, in regard to fossils of any particular form, is not peculiar to these stones, as witness the small shells petrified and found in Ægypt, which from their flat and roundish shape, are said to be the lentiles which the children of Israel eat when making the pyramids; the *cornua ammonis*, which is the remains of a sea shell, and yet is supposed to be a petrified serpent; the *nummi minerales*, which are the operculums of shell-fish, but are generally supposed by the vulgar, about the places where they are found, to be medals and coins, petrified with lying in the earth, and many the like follies. *Breyn.* de Melon. Petr. Mont. Carm.

MELON *Thistle*. See the article MELOCACTUS.

MELONGENA, *Mad Apple*, in botany, the names of a genus of plants, the characters of which are these: The flower consists of one leaf, and is of a rotated form, and divided into several segments at the edges. The pistil arises from the cup, and is fixed in the manner of a nail to the middle part of the flower. This afterwards changes to a fleshy fruit, in which there are contained a number of kidney-shaped seeds.

The species of *Melongena*, enumerated by Mr. Tournefort, are these: 1. The long violet-fruited *Melongena*. 2. The *Melongena* with long white fruit. 3. The *Melongena* with long yellow fruit. 4. The *Melongena* with long bright red fruit. 5. The *Melongena* with cylindric violet-coloured fruit. 6. The round fruited *Melongena*. 7. The crooked-fruited *Melongena*. 8. The thorny *Melongena*, with round saffron-colour'd fruit. 9. The *Melongena* with round fruit, armed with violet-colour'd thorns. 10. The *Melongena* with round fruit, armed with greenish white thorns. 11. The *Melongena* with prickles, and with a round black fruit. 12. The prickly *Melongena*, with a long black fruit. *Tourn.* Inst. p. 151.

This plant is propagated in the gardens of the curious with us; and in Spain, Italy, and Barbary, common in the kitchen gardens, the fruit of them being frequently eaten there boiled with fat flesh, putting thereto some scraped cheese, and preserving it through the winter with vinegar, honey, or salt pickle. This they esteem of great efficacy to provoke venery. In summer also, when the fruit is just ripe, they eat it fresh dressed, with spices and other ingredients.

The manner of propagating them with us, is to sow the seeds in March, upon a moderate hot bed, and when the plants are come up, they are to be thinned by planting them in another

hot bed at about four inches afunder, watering and fhading them till they have taken root. They muft afterwards have as much air as the feafon will allow, and in May they muft be tranfplanted into a warm border, fetting them at two foot diftance every way. About the middle of June the fruit will appear, and if the weather be dry at this time, they muft be often watered, which will make the fruit grow large. The fruit ripens in the end of July. *Miller*'s Gardener's Dict.

MELOPEPO, in botany, the name of a genus of plants, of a middle nature, as their name expreffes, between the melon and the pompion. The characters which diftinguifh this genus from the others of the like kind, are, that the fruit is roundifh, ftriated, angular, and ufually deeply divided into five parts. The feeds are flat, and fixed to a fpongy placenta.

The fpecies of this genus, enumerated by Mr. Tournefort, are thefe: 1. The flatted or compreffed *Melopepo*. 2. The great white-fruited *Melopepo*. 3. The yellow rough-fruited *Melopepo*. 4. The broad depreffed *Melopepo*. 5. The citron-fhaped *Melopepo*. 6. The conic *Melopepo*. 7. The *Melopepo* with a doubly turbinated fruit. 8. The yellow thin-fkinned *Melopepo*. 9. The clypeated, or fhield *Melopepo*. 10. The verrucofe or warted *Melopepo*. 11. The tuberofe warted *Melopepo*. 12. The lightly ftriated yellow warty *Melopepo*, with rough leaves. 13. The white lightly ftriated warty *Melopepo*, with rough leaves. 14. The warty *Melopepo*, with a white fruit and white feeds.

MELOTIS, a word ufed by the chirurgical writers to exprefs a fmall probe, properly one intended to be ufed only to the ear.

MELT (*Cycl.*)—MELT *of Fifhes*. In the *Melt* of a living cod-fifh there are fuch incredible numbers of thofe fmall animalcules found in the male feed of all animals, that in a drop of the juice of it, no more in quantity than a fmall grain of fand, there are contained more than ten thoufand of them; and, confidering how many fuch quantities there are in the whole *Melt* of one fuch fifh, it is not exceeding the bounds of truth to affirm, that there are more animals in one *Melt* of it, than there are living men at one time upon the whole face of the earth. However ftrange and romantic fuch a conjecture may appear at firft fight, a ferious confideration, and calculation, will make it appear very plain. An hundred fuch grains of fand as are here mentioned, will make about an inch in length; therefore in a cubic inch there will be a million of fuch fands.

The *Melt* of one of thefe fifhes is frequently about the quantity of fifteen cubic inches, it muft therefore contain fifteen millions of quantities as big as one of thefe fands; and if there be ten thoufand animals in each of thofe quantities, there muft be, in the whole, a hundred and fifty thoufand millions: Which is a number vaftly exceeding the number of mankind, even tho' we were to fuppofe the whole earth as populous as Holland. See Philofophical Collections, p. 4.

MELTING (*Cycl.*)—MELTING *Cone*, in affaying, is a fmall veffel made of copper or brafs, of a conic figure, and of a nicely polifhed furface within. Its ufe is to receive melted metals, and ferve for their precipitation, which is effected, when two bodies melted together, and yet not mixing perfectly with one another in the fufion, feparate in the cooling into two ftrata, on account of their different fpecific gravity. This precipitation might be made in the fame veffel in which the fufion is performed; but then the melting-pot or crucible muft be broken every time to get it out, whereas the conic fhape, and polifhed furface of this veffel, makes it eafily got out without violence. The fhape of this veffel is alfo of another ufe in the operation; for by means of it, the heavy matter fubfiding to a point, is formed into a perfect and feparate regulus, even where the whole quantity, as is very frequently the cafe, has been but very fmall.

When the quantity of the melted matter is great, it is common to ufe, inftead of this cone, a large brafs or iron mortar, or any other conveniently fhaped brafs or iron veffel. It is neceffary, when the cone is of brafs, to be cautious that it be not made too hot; for the brittlenefs of that metal, when hot, makes it eafily break, on the ftriking with any force on that occafion, to make the melted mafs fall out.

Thefe, and all other moulds for the receiving melted metals, muft always be well heated before the mafs is poured into them, left they fhould have contracted a moifture from the air, or have been wetted by accident; in which cafe the melted metal will be thrown out of them with great violence and danger. They ought alfo to be fmeared over with tallow on their infide, that the regulus may be the more eafily taken out of them, and the furface of the mould not corroded by the melted mafs poured in.

If a very large quantity of a metal is, however, to be received into them, and efpecially if any thing fulphureous have place among it, this caution of tallowing the moulds does not prove fufficient; for the large quantity of the mafs makes it continue hot fo long, that this becomes but a flight defence to the furface of the mould. In this cafe the affayer has recourfe to a lute, reduced to a thin pap with water, which being applied in form of a very thin cruft, all over the infide of the cone, or mould, foon dries up indeed, but always preferves the fides of the veffel from the corrofion of the mafs. And this caution is found neceffary, even when pure copper is melted alone, without any mixture of fulphur. See Tab. of Chemiftry, N°. 31. *Cramer*, Art. Aff. p. 72.

MEMÆCYLUM, in botany, a name by which fome authors have called the *arbutus*, or ftrawberry-tree, a fhrub preferved in the gardens of the curious. *Ger.* Emac. Ind. 2.

MEMAICULA, in the materia medica of the antients, a name given to a fruit, ordered in fome compofitions as an aftringent and a cooler. When the Greek writers ufe this word, their Latin tranflators ufually render it by the word *unedo*. Pliny fays, that *unedo* is the name of the fruit of the *arbutus*, or ftrawberry-tree; but we find the earlieft Latin writers do not countenance this. Varro calls the fruit of the *arbutus* by the name *arbutus*, as he does the fruit of the mulberry or morus, by the name *morus*. And it feems to have been contrary to the general cuftom of the times to have impofed a name upon a fruit, different from that of the tree which bore it. Some of the commentators fay that the *Memaicula*, or *Unedo* was no other than the common wood-ftrawberry. And Ægineta in one place fays, that the fruit of the *camarus*, that is, of the *arbutus*, was called *Memaicula*; but in another place he gives a much better explication of the word, faying, that fome of the Greeks ufed it as the name of the fruit of the *cornus mas*, or male cornel-tree. See the article CORNUS.

MEMBRANE (*Cycl.*)—Mr. Lewenhoek has been at the pains of examining, with great nicety, the fine *Membranes* which enclofe the fafciculi or fmall bundles of fibres of which a mufcle is compofed. Between thefe fafciculi the *Membrane* is of a confiderable thicknefs; but it divides itfelf every way into very fine and fmall branches. This *Membrane* is evidently compofed of a number of fmall veffels, and thefe may be diftinguifhed not only in its thick parts, but even where it is ever fo fmall and fine, fo far as the microfcope can trace it; but this is not fo far as might be wifhed; for the *Membrane* ftill divides itfelf in its progrefs into more and more ramifications, and where it envelopes only a fingle fibre, is not to be diftinguifhed with any degree of precifion, even with the beft microfcopes. The fmall veffels extended through this *Membrane*, are doubtlefs intended to convey nourifhment to it; but it is very certain, that the globules of blood can never pafs into fuch fmall canals. Phil. Tranf. N°. 122. p. 140.

Adipofe MEMBRANE, *Membrana Adipofa*. It was the opinion of Boerhaave that the feat of the *lues venerea*, or pox, was in the *Membrana Adipofa*. There are many feeming difficulties which have prevented the generality of the learned world from giving into this; but there have been feveral particular cafes, the fymptoms of which feem to prove it really to be fo.

Of thefe Dr. Huxam gives one, which alone may feem fufficient to prove the reality of it. This is of a gentleman of about 27 years of age, and of a hot bilious conftitution, who fome years before his death had got a gonorrhœa, and before that was well cured, a fecond, and after that a third; and after all thefe, had frequent impure converfations with the negro women in the Weft Indies, who probably had that worft fpecies of pox, the yaws. He had, after this, a terrible itching under his fkin, and a terrible ftinking breath, and fpit corrupt matter, but had no running ulcer, bubo, node, or other of the common fymptoms of a confirmed pox; but after repeating his rafh conduct with fome women in England, he had a Gonorrhœa of which he could not get cured; but a bubo appeared in the groin, and verrucofe fwellings about the anus.

One of thefe breaking difcharged a great quantity of matter, and after that others appeared, the bubo would not fuppurate, and fcabs appeared in feveral parts of his body. He was fumigated with cinnabar, and a falivation propofed; but after taking, at times, five drams of calomel, he had not the leaft forenefs of the gums, though that medicine had not purged nor vomited him. At length turbith vomits, and large dofes of mercurials, to which he had been much accuftomed before, brought on a forenefs of the mouth; but the fpitting was tough, and did not amount to a pint a day. During this courfe the fcaly eruptions encreafed, and he was at length covered with them all over, and his limbs fwelled, and even burft in many places, the fiffures difcharging a ftinking ichorous matter.

Hot baths and mercurial ointments were ufed on this, but the difeafe ftill encreafed under thefe means; the fcales grew fo ftiff, that he could not move his limbs, and ulcers appeared in many parts, particularly a large tumour on each breaft, which difcharged vaft quantities of an oily ftinking matter. It was obfervable, that where thefe tumours and ulcers appeared, they only ran under the fkin, being entirely feated in and feeding on the *Membrana Adipofa*, fo that the mufcles and tendons underneath appeared as fair and florid as in the moft healthy conftitution.

It was now plain, that mercury could do nothing toward a cure in any form, and the old method of fweating was attempted with warm baths, to loofen the fcales; by this means they came off apace in the manner of thofe of the confluent fmall pox, but larger, fome of thefe being four or five inches over. In a week's time, the coat of mail was cleared off,

off, and his breath became ſweet; but the ulcers ſtill diſcharged great quantities, and notwithſtanding all that had been done, two large ſhankers appeared on the glans, and a bubo in each groin: He was alſo ſeized with a cough, and ſpit purulent and bloody matter. It was evident that the whole *Membrana Adipoſa* had been conſumed from the external part of the body, and the diſeaſe now began to ſeize on that part of it which inveſted the more vital parts; but nature could ſupport it no longer, and he died in the moſt extreme degree of a pocky conſumption. It is obſervable, that not one bone in the whole body appeared to be touched, though he died with more than forty ulcers upon him. Phil. Tranſ. N°. 460. p. 671.

MEMBRANACEOUS *Leaf*, among botaniſts. See the article LEAF.

MEMBRAS, in ichthyology, a name given by Rondeletius, Aldrovand, and ſeveral other writers, to the *halec* or herring. See the articles HALEC and CLUPEA.

MEMIREN, in the materia medica, the name by which Serapion and ſome other authors have called the pilewort, or ſmall celandine. *Ger.* Emac. Ind. 2.

MEMITHA, in the materia medica of the antients, the name of a plant which ſome have ſuppoſed to be our cerinthe, but others the glaucium, or yellow-horned poppy.

MEMORY (*Cycl.*)—Many have been the attempts, in all ages, to aſſiſt the *Memory*. Some have had recourſe to medicine, ſuch as Horſtius [a], Marſilius Ficinus [b], Johnſton [c], and others. That good health, a good digeſtion, and a mind free from care, are helps in this reſpect, is an old obſervation [d]. That attention, application, frequent recapitulation, are neceſſary, is known to every one. But whether, beſides natural health and parts, and the exerciſe of our faculties, art may not give a farther aſſiſtance to *Memory*, has been a queſtion. Simonides is ſaid to be the firſt who found out the art of *Memory* [e]. His method was by a choice of *places* and *images*, as a repoſitory of ideas; ſuch, for inſtance, as a large houſe divided into ſeveral apartments, rooms, cloſets, &c. All theſe, and their order, were to be rendered extremely familiar to the imagination and *Memory*. Then, whatever was to be remembered, was by ſome ſymbolical repreſentation or another, as an anchor for navigation, to be connected with ſome part of the houſe, or other artificial repoſitory, in a regular manner. Cicero [f] and Quinctilian [g] give us ſome account of this method, and ſpeak of it with reſpect. Several moderns have attempted improvements of artificial *Memory*. There was a collection of various treatiſes of this kind publiſhed at *Leipzig* [h]; this and Bruxius's Simonides Redivivus [i] are commended by Morhof [k]. Paſchius gives us ſome account alſo of ſeveral authors who have treated of this art [l]. It is certainly of uſe in hiſtory and chronology. The chief artifice, in this reſpect, is to form an artificial word, the letters of which ſhall ſignify numbers. Hence a date or æra may more eaſily be recapitulated and remembred than without ſuch a contrivance. This invention is mentioned as a ſecret known to few, by Paſchius [m]. It has been proſecuted lately in England [n], by Dr. Grey.—[[a] De Sanitat. Studioſor. lib. 2. c. 1. [b] De Vita, lib. 1. c. 25. [c] *Johnſton*, Idea Medicin. Practic. lib. 8. c. 4. Vid. *Paſch.* de Nov. Invent. p. 134. [d] *Quinctil.* Inſt. Orat. p. 992. [e] *Quinct.* lib. cit. p. 985. [f] Ad Herenn. lib. 3. [g] Lib. cit. [h] Variorum de Arte Memoriæ Tractatus, Lipſ. 1678. 8°. [i] Polyhiſtor. lib. 1. p. 374, 375. [k] *Adami Bruxii*, Simonides Redivivus, ſeu Ars Memoriæ & Oblivionis. Lipſ. 1640. in 4°. [l] Lib. cit. p. 133—140. [m] Lib. cit. p. 140. *Numerus per certas literas, verbo memoriali comprehenſas, exprimitur.* [n] Vid. *Memoria Technica*, or a New Method of Artificial Memory, &c. Lond. 1730. 8°. alſo *Lowe*'s Mnemonics.]

The method is this: To remember any thing in hiſtory, chronology, geography, &c. a word is formed, the beginning whereof being the firſt ſyllable or ſyllables of the thing to be remembred, does, by frequent repetition, of courſe draw after it the latter parts, which is ſo contrived as to give the anſwer. Thus in hiſtory, the deluge happened in the year before Chriſt 2348. This may be ſignified by the word Dél-*étok*; Del ſtanding for deluge, and *etok* for 2348. How theſe words come to ſignify theſe things, or contribute to the remembring them, is now to be ſhewn.

The firſt thing to be done, is to learn exactly the following ſeries of vowels and conſonants, which are to repreſent the numerical figures, ſo as to be able at pleaſure to form a technical word, which ſhall ſtand for any number, or to reſolve a word already formed into the number it ſtands for.

a	*e*	*i*	*o*	*u*	*au*	*oi*	*ei*	*ou*	*y*
1	2	3	4	5	6	7	8	9	0
b	*d*	*t*	*f*	*l*	*s*	*p*	*k*	*n*	*z*

Here *a* and *b* ſtand for 1, *e* and *d* for 2, *i* and *t* for 3, and ſo on. Theſe letters are aſſigned arbitrarily to the reſpective figures, and may very eaſily be remembred. The firſt five vowels in order naturally repreſent 1, 2, 3, 4, 5. The diphthong *au* being compoſed of *a*, 1, and *u*, 5, ſtands for 6; *oi* for 7, being compoſed of *o*, 4 and *i*, 3; *ou* for 9, being compoſed of *o*, 4 and *u*, 5: The diphthong *ei* will eaſily be remembered for 8, being the initials of the word. In like manner for the conſonants, where the initials could conveniently be retained, they are made uſe of to ſignify the number, as *t* for 3, *f* for 4, *s* for 6, and *n* for nine. The reſt were aſſigned without any particular reaſon, unleſs that poſſibly *p* may be more eaſily remembred for 7 or *ſeptem*, *k* for 8, or ὀκτω, *d* for 2, or *duo*; *b* for 1, as being the firſt conſonant, and *l* for 5, being the Roman letter for 50, than any others that could have been put in their places. Memor. Techn. p. 2, 3. 'Tis farther to be obſerved, that *z* and *y* being made uſe of to repreſent the cypher, where many cyphers meet together, as 1000, 1000000, &c. inſtead of a repetition of *azyzyzy*, &c. let *g* ſtand for 100, *th* for a thouſand, and *m* for a million. Thus *ag* will be 100, *ig* 300; *oug* 900, &c. *ath* 1000, *am* 1000000, *loum* 59000000, &c. Ib. p. 5.

Fractions may be ſet down in the following manner: Let *r* ſignify the line ſeparating the numerator and denominator, the firſt coming *before*, the other *after* it; as *iro* $\frac{3}{4}$, *urp* $\frac{5}{7}$, *pourag* $\frac{79}{100}$, &c. When the numerator is 1 or unit, it need not be expreſſed, but begin the fraction with *r*; as *re* $\frac{1}{2}$, *ri* $\frac{1}{3}$, *ro* $\frac{1}{4}$, &c. So in decimals, *rag* $\frac{1}{100}$, *rath* $\frac{1}{1000}$. Ibid.

This is the principal part of the method, which conſiſts in expreſſing numbers by artificial words. The application to hiſtory and chronology is alſo performed by artificial words. The art herein conſiſts in making ſuch a change in the ending of the name of a place, perſon, planet, coin, &c. without altering the beginning of it, as ſhall readily ſuggeſt the thing ſought, at the ſame time that the beginning of the word, being preſerved, ſhall be a leading or prompting ſyllable to the ending of it ſo changed. Thus, in order to remember the years in which Cyrus, Alexander, and Julius Cæſar, founded their reſpective monarchies, the following words may be formed; for Cyrus, Cyr*uts*; for Alexander, Alex*ita*; for Julius Cæſar, Jul*ios*. *Uts* ſignifies, according to the powers aſſigned to the letters before mentioned, 536; *itu* is 331, and *os* is 46. Hence it will be eaſy to remember, that the empire of Cyrus was founded 536 years before Chriſt, that of Alexander 331, and that of Julius Cæſar 46. Mem. Techn. Introd. p. viii and ix.

For the farther application of this method, we refer to the ingenious author of the laſt cited book. We ſhall only add, that *technical verſes* contribute much to the aſſiſtance of the *Memory*, both as they generally contain a great deal in a little compaſs, and alſo becauſe, being once learned, they are ſeldom or never forgot. The author before quoted has given us ſeveral ſpecimens of ſuch verſes in hiſtory, chronology, geography, and aſtronomy, as alſo the Jewiſh, Grecian and Roman coins, weights and meaſures, &c. He adviſes his reader to form the words and verſes for his own uſe himſelf; as he perhaps will better remember them than thoſe formed by the author. Lib. citat. Introduct. p. xi.

It was a practice among the Jews not only to abbreviate ſentences and names of many words, by putting together the initial letters of thoſe words, and making out of them an artificial word to expreſs the whole, as *Rambam* for *Rabbi Moſes ben Maimon*; but they alſo made uſe of natural words to repreſent numbers, when they could meet with ſuch as happened to anſwer the number which they wanted to expreſs [a]. It is to obſervations of this kind the author laſt quoted ſeems to ſay he owed the firſt hints of his method [b].—[[a] Mem. Tech. Introd. p. xv, xvi. [b] Lib. cit. p. xvii.]

As to Simonides's method, Quinctilian ſays he will not deny it to be of ſome uſe; for inſtance, in repeating a multitude of words in the order they occur, and in things of this nature: But he thinks it of leſs uſe in getting by heart a continued oration, and in this reſpect rather an incumbrance [a]. He himſelf adviſes, if the ſpeech to be remembred be long, to get it by heart in parts, and thoſe not very ſmall. The partition ought chiefly to be made according to the different topics. He thinks it beſt to get things by heart tacitly, and if, the better to fix the attention, the words be pronounced, yet it ſhould be in a low voice. Apt diviſions help the *Memory* greatly. But after all, the great art of *Memory* is exerciſe: To get many things by heart, and daily, if poſſible. Nothing increaſes more by uſe, or ſuffers more by neglect, than the *Memory*. At whatever age a man aims at the improvement of this faculty, he ſhould patiently ſubmit to the uneaſy labour of repeating what he has read or written. Here, as in other caſes, where habits are to be acquired, exerciſe ſhould be increaſed by degrees [b].—[[a] *Nonne impediri eorum, quæ dicit, decurſum neceſſe eſt duplici memoriæ cura? Nam quomodo poterunt copulata fluere, ſi propter ſingula verba ad ſingulas formas reſpiciendum erit.* *Quinct.* Inſt. Orat. Lib. xi. c. 2. p. 989. [b] *Quinct.* loc. cit. p. 993. ſeq.]

Lord Bacon enumerates ſeveral helps to *Memory*, as order, artificial place, verſe, whatever brings an intellectual thing to ſtrike the ſenſes, and thoſe things which make an impreſſion by means of a ſtrong paſſion, as fear, ſurprize, &c. Thoſe things alſo ſink deepeſt, and dwell longeſt in the *Memory*, which are impreſſed upon a clear mind unprejudiced either before or after the impreſſion; as the things we learn in childhood, or think of juſt before going to ſleep; as likewiſe the firſt times things are taken notice of.

A multitude of circumftances alfo, or, as it were, handles or holds to be taken, help the *Memory*; as the making many breaks in writing, reading or repeating aloud: But as to this laft, fee Quinctilian's opinion before mentioned. Thofe things which are expected, and raife the attention, ftick better than fuch as pafs flightly over the mind; whence if a man reads any writing twenty times over, he will not remember it fo well, as if he read it but ten times; with trying between whiles to repeat it, and confulting the copy where his *Memory* failed. *Bacon*'s Works abrid. vol. 2. p. 475. See alfo vol. 1. p. 135, 136. vol. 3. p. 176. and the article MNEMONIC *Tables*.

Weaknefs of the MEMORY, in many cafes, is to be confidered as a difeafe, and is looked on in that light by the medical writers, who have prefcribed various remedies for it. The principal caufes of this debility, are a too frequent and conftrained ufe, or rather abufe of it, in the getting by rote numbers of words and fyllables, particularly in the learning different languages; a paralytic affection in the head; violent external injuries in the fame part; violent pains in the head, attended with deliriums, or attending a phrenitis. And to thefe are to be added drunkennefs, and an abufe of venery.

Prognoftics. All debilities of *Memory* are cured with great difficulty by medicines alone; and indeed this complaint is feldom removed, unlefs the whole frame of mind and courfe of life be altered; all paffions avoided, and excefs of every kind left off. But of all other kinds, that debility of *Memory* which proceeds from a paralytic diforder of the head, particularly when that diforder affects the tongue, is found to be the moft obftinate and difficult of cure. Much fleep, or exceffive waking, are equally hurtful to the *Memory*, and frequently bring on an almoft total lofs of it.

Method of treatment. All fuch medicines as are of an agreeable tafte or odour, are generally fuppofed to be of fervice in ftrengthening the *Memory*; and lignum aloes, ambergrife, and fome other of the fcented drugs, have been known to do great good. The aromatic, volatile, and fpirituous medicines, alfo all help in this cafe, if taken in fmall dofes, and continued for a long time together. The analeptics and nervine medicines are alfo greatly recommended, but they are feldom found of ufe; for among people afflicted with a debility of *Memory*, many are thofe of robuft conftitutions and ftrong appetites, who eat already more than nature requires, and have therefore very little ufe for analeptics or nutritive things.

Bleedings in fmall quantities frequently repeated, in cafes where there is no contrary indication, frequently prove of great fervice in this cafe; but the *primæ viæ* are firft to be cleanfed before fuch a courfe is entered upon. Many greatly recommend bags of aromatics to the head, to be conftantly worn in caps; but it is much to be feared thefe can have but very little effect. *Junck.* Confp. Med. p. 682.

MEN *allegro*, in the Italian mufic, is ufed to denote a movement not fo brifk and lively as *allegro*. See the article ALLEGRO.

MEN *forte*, in the Italian mufic, intimates that the part to which it is added ought to be played or fung not fo ftrong or fo loud as the reft.

MEN *prefto*, in the Italian mufic, fignifies lefs quick. See the article PRESTO.

MENALD *deer*, a fpecies of the common fallow deer, beautifully variegated. See the articles CERVUS and DEER.

MENENCHYTA, in medicine, certain compofitions of medicinal ingredients made for injecting into the womb, in the cure of feveral difeafes of that part.

MENINGOPHYLAX, a word ufed by Celfus as the name of a chirurgical inftrument, contrived for guarding the membranes of the brain while the bone of the cranium is rafped or cut, after the operation of the trepan.

MENING, in botany, a name given by the people of Guinea to a plant of the ricinus or palma Chrifti kind, which they ufe in medicine: They dry and powder the leaves, and then give them to be fnuffed up the noftrils to cure all forts of ftuffings or ftoppages in the head. Its leaves refemble thofe of the finch and ivy, and are hairy; whence Petiver has named it *ricinus Guineenfis hæderæ quinquefoliæ Virginianæ facie foliis hirfutis*. It is not known to grow any where in America. Phil. Tranf. N° 232.

MENOGENIEN, in botany, a name by which fome authors have called the pæonia, or common garden piony. *Ger.* Emac. Ind. 2.

MENSARII, among the Romans, officers appointed to manage the public treafury, being fometimes three, and fometimes five in number. *Pitifc.* in voc.

MENSORES, among the Romans, harbingers or officers, whofe bufinefs it was to go and fix upon lodgings for the emperor, when he took a journey to any of the provinces. Their office was alfo to mark out encampments, and affign every regiment its poft. *Danet.* in voc.

MENSORES alfo fignified land-furveyors, architects, or appraifers of houfes and public buildings. Thofe likewife who diftributed the provifions in the army, were called *menfores frumentarii*; and fervants who waited at table had the appellation of *Menfores*. *Pitifc.*

MENSORES was likewife the title of officers among the Romans, appointed to receive the provifions brought to the city by fea, and to fee them carefully laid up and preferved in public granaries, of which there were great numbers. *Hoffm.* Lex. in voc.

MENSTRUUM (*Cycl.*)—As many more things might be done in chemiftry than we now find practicable if we had more *Menftruums* than are at prefent known, it muft be a fubject of infinite ufe in chemiftry to difcover new ones. To this purpofe let it be confidered, that in whatever way falts are united with other falts, new *Menftruums* are produced by the mixture.

Thus if pure alkali be added to a folution of fea falt, earthy matter is precipitated, and the falt afterwards obtained by criftallization, from the clear liquor, will be a fea falt much purer than before, and capable of acting on bodies in a different manner.

The fame fixed alkali being added to the brine of nitre, makes the liquor thick and milky, and precipitates an earthy matter; after which the nitre, obtained by criftallization, is much purer than before.

When fixed alkali is added to the brine of fal armoniac, it lays hold of the acid of that falt, and fets the volatile alkali of the compofition free, and fuffers it to fly off in the air, leaving only a very pure and fixed fea falt at the bottom of the veffel. If a pure volatile alkali be added to the brine of fea falt, it makes the liquor thick, then purifies it, and flies off; and it does the fame when added to a folution of nitre; and when added to a folution of fal armoniac, it, in like manner, purifies the falt without altering its nature, and flys off as it was poured on. Vegetable acids produce but little alteration on being mixed with fea falt, nitre, and fal armoniac. Fermented vegetable acids, even after being purified by diftillation, produce no great alteration when mixed with the fame falts. If calcined vitriol, or alum, be mixed with nitre and diftilled, they yield aqua fortis, which contains nothing of the acid of vitriol or alum, but is a mere fpirit of nitre; and if mixed with fea falt, and treated in the fame manner, the produce is a fpirit of falt; and if with nitre and fea falt together, they make an aqua regia. So if nitre and calcined vitriol be melted together in an open fire, the acid of the nitre is difcharged, and a kind of tartarum vitriolatum is left behind. Sea falt, treated in the fame manner, leaves a fort of Glauber's falt behind; and, in general, what way foever it be by which falts are joined with falts, new faline productions, and new *Menftruums* will arife; whence the art of chemiftry may be perpetually improved, and new *Menftruums* will give new phænomena on different bodies. New *Menftruums* of particular virtues, may alfo be made by varioufly combining the known *Menftruums* together; and this may be done by an almoft infinite variety of ways; much may be alfo done by reducing every known *Menftruum* to its utmoft degree of purity. And, laftly, by reducing fome of them into the minuteft particles, they can be reduced to, whether by art or nature; for upon thefe three particulars the extraordinary fkill of the chief chemifts feems principally to depend. For inftance, fuppofe an extremely pure, ftrong, and fubtle fermented vegetable acid was wanting: Take fine verdegreefe prepared from copper corroded by the fubtile vapour of a fermenting acid; add to it twenty times its weight of the ftrongeft diftilled vinegar that can be made; digeft them together till the verdigreefe is thoroughly diffolved, and the whole become a deep green liquor; purify this by filtration, and infpiffate it over a gentle fire to a pellicle; fet it in a quiet place, where it will fhoot into cryftals like emeralds, confifting of an acid vinegar and diffolved copper; pour off the liquor, collect the cryftals, and evaporate as before; and by this means collect all the cryftals that can be obtained; then dry thefe, and diftil them in a retort, and the produce will be a moft pure and ftrong vegetable acid, not in the leaft partaking of the nature of copper. But this experiment will not fucceed with lead, tin, or any other of the metals foluble in vinegar; for the copper attracts the acid free of its water, and again reftores it unaltered; but the others, though they equally attract and feparate it, yet always yield it altered and impure. Zwelfer imagined this acid to be the alkaheft, or univerfal diffolvent; but Tachenius foon proved that it was no other than diftilled vinegar of a much greater purity than ufual.

To fhew that by the compounding one *Menftruum* with another, new, and often, excellent falts may be produced, let it be confidered, that the regenerated tartar, properly prepared, may be intimately united to pure alcohol, and thus produce a vegetable *Menftruum*, compofed by the moft clofe union of the moft fubtile vegetable particles, *viz.* alkali, acid, and fulphur; whence the effect of fuch a liquor cannot but be extremely great, both as a *Menftruum* and a medicine. So again, if a pure ftrong alkaline fpirit be united with pure alcohol, it produces an admirable *Menftruum* called the offa Helmontii, which intimately diffolves diftilled vegetable oils, and thus makes a *Menftruum* compounded of the genuine vegetable fulphur, and an alkali, and is perhaps one of the beft medicines, as well as the beft *Menftruums* hitherto known.

In

In like manner pure spirit of nitre saturated with the alkaline spirit of sal armoniac, makes a kind of volatile nitre, and thus affords an opportunity of examining, by experiments, whether the great things expected from a volatile nitre by the chemists, will be performed by it or not. Experiments of this kind are extremely worth prosecuting. It is not certain whether any *Menstruum* will dissolve any substance without the assistance of fire, as no experiment could ever be made in any place destitute of all fire; there being evidently fire in our utmost known degree of cold; and we all know that *Menstruums*, of whatever kind, act greatly the better for being assisted by heat.

Menstruums can scarce act as such, unless reduced to a fluid form, or at least approaching thereto; this is chiefly given them by means of fire, air, water, and triture: These are the four causes which usually excite the latent powers of *Menstruums*. Certain *Menstruums* contain a cause within themselves apparently capable of exciting motion, though in reality it depends upon the near approach of some other body. Thus if a good loadstone be suspended by a thread, and hang at rest in a great degree of cold, it will seem to have no active virtue; but if iron come near it, a motion is produced in both these bodies, till they come together, and remain in contact; and this kind of power generates motion spontaneously, without the assistance of any fire sensible to us, and is not excited by motion. So likewise strong spirit of nitre confined in a close vessel, yields an acid fume constantly playing about the surface of the liquor, and issuing out whenever the vessel is unstopped. So also the alkaline spirit of sal armoniac yields a fume never observed to be at rest; and the spirit of this salt, made with lime, yields a fume much more volatile and moveable: All the bodies of this kind therefore strangely retain, and strangely excite motion. We are always to remember also that air, even in the coldest places, has always a strong vibratory motion, and therefore may often excite these motions in these bodies; as on the other hand solutions are often immediately performed by means of the motion peculiar to the *Menstruum* arising from it; while another motion of a different kind, and proceeding from a different cause, would not produce the effect. Thus, for instance, if a fine piece of English chalk be calcined in a strong fire, or even in the focus of a burning-glass, it will scarce alter its nature by this violent motion, nor again by being exposed to a hot or cold air, either at rest, or agitated by winds; and though if long boiled in water, or a brine of salt of tartar, it will not dissolve; yet it immediately melts and disappears when put into cold vinegar. Whence we see there is a very great difference between the motion excited by the reciprocal force of the solvent and solvend, and the motion excited by fire, air, water, and impulse. The acrimony of a *Menstruum*, with respect to a human body, so as to excite pain, corrode or consume the parts thereof, is no sign that such a *Menstruum* is suited to dissolve other bodies, as appears from oil of vitriol, spirit of nitre, spirit of salt, and *aqua regia*, which though they readily consume flesh, yet do not consume or dissolve wax and sulphur, though these two may be easily dissolved in the body. Many bodies incapable of solution in certain *Menstruums*, may be suited for dissolving therein, by being previously dissolved in other *Menstruums*. Thus if common sulphur be boiled ever so long in alcohol, it dissolves no more than a stone in water; but if the sulphur be first melted with salt of tartar into a dusky mass, the alcohol will then dissolve it; so also powdered antimony remains untouched after boiling in alcohol; but if first boiled to a dry mass in an alkaline lixivium, this mass presently yields a golden tincture to alcohol. Some chemists have conceived so highly of this regular and successive application of different *Menstruums*, particularly Mr. Boyle and Mr. Homberg, that they say even metals may by this means be resolved into their component running mercury and fixing sulphur. Thus they assert, that if silver be first dissolved in spirit of nitre, and then long digested with pure fixed alkali, and afterwards several times sublimed with sal armoniac, it will at length, by means of these resuscitating salts, afford a true running mercury; in which operation the acids procure an entrance for the alkalis into the substance of the metal, as the fixed alkalis procure admission to the volatile ones, which else could not enter. Boerhaave waves disputing upon the point, whether the metals can be thus resolved into their running mercuries, and only affirms, that after many trials, he was never able to effect it. *Boerh.* Chem. part 1. p. 562. seq.

It is an error to think a *Menstruum* cannot be too strong. Oil of vitriol diluted with several times its weight of water, dissolves iron best. So aqua fortis diluted works best in lead. And Mr. Boyle makes the like observation as to the solution of silver. Works Abr. vol. 1. p. 165.

Animal MENSTRUUM. There are of the animal *Menstruums* very many both of the natural and artificial kind; the natural are blood, serum, gall, urine, saliva, rennet, whey, buttermilk, &c. most of which, being properly employed, will either produce or discharge colours, and might be made serviceable in the painting and dying trades. Thus recent urine discharges the common ink out of linnen, &c. Blood affords, by proper management, the noble Prussian blue; and gall is a natural yellow, well deserving to be treated in the manner of blood in that preparation. Of the artificial kind are the spirit of urine produced by chemistry, which serves to produce, alter and destroy a vast number of colours. The liquors distilled from recent, or fermented whey, buttermilk, &c. might be also found of great value; and variously compounding these several animal substances, even by random trials, or chance experiments, new discoveries in colours might be made; though much more, probably, by a right reasoning and analogy. As for instance, the common bones burnt to a blackness, being found to afford the bone black, the experiment was easily transferred to ivory, and so the ivory black was discovered: And so of the rest. *Shaw's* Lectures. p. 183.

MENSTRUUM *Peracutum*. Mr. Boyle gives the name of *Menstruum peracutum* to a *Menstruum* made by pouring on the rectified oil of butter of antimony as much strong spirit of nitre as would serve to precipitate out of it all the bezoarticum minerale; and then with a smart fire distilling off the liquor which would come over, and cohobating it upon the antimonial powder. Works Abr. vol. 1. p. 260, 377.

He put some highly refined gold into a large proportion of this *Menstruum peracutum*, where it dissolved slowly and quietly; and he found at the bottom of the glass a considerable quantity of a white powder, which the *Menstruum* would not touch, and which was also indissoluble in aqua regia. The solution of gold being abstracted, and the gold again reduced into a body, yielded, upon a second solution, more of the white powder. This powder he melted down into a metal, answering in colour, malleability, solubility in aqua fortis, and in bitterness to the taste of that solution, to silver. Hence he infers, that notwithstanding the supposed unchangeableness of gold, this experiment shews it to be really changeable into silver, or at least into a new kind of metal very different from gold. And he therefore concludes, that there is no impossibility in the nature of the thing, that one metal should be transmuted into another. Ibid. p. 260—262.

By dissolving gold in this *Menstruum peracutum*, Mr. Boyle also tells us, he made the gold rise in the retort, in the top and neck of which it was found in the form of yellow and reddish sublimate. Works abr. vol. 1. p. 263, 377.

We do not find that Mr. Boyle gave the name of *Menstruum peracutum* to the *Menstruum* he extracted from bread, as it is said he did, in the Cyclopædia, under the head MENSTRUUM. See Boyle's Works Abr. vol. 1. p. 34, 49.

MENTHA, *Mint*, the name of a well known genus of plants, the characters of which are these: The flower consists of one leaf, and is of the labiated kind; the upper lip is arched, and the lower is divided into three segments; and the whole is so disposed, that at first sight the flower appears a four-leav'd one, or at least one regularly divided into four segments. The pistil arises from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and surrounded with four embryos which afterwards become so many seeds, and are contained in the cup of the flower.

The species of *Mint*, enumerated by Mr. Tournefort, are these: 1. The common round-leav'd wild *Mint*. 2. The purple-flower'd round-leav'd wild *Mint*. 3. The verticillated garden *Mint*, with the smell of basil. 4. The common curled-leav'd verticillated *Mint*. 5. The round-leav'd spiked curled *Mint*. 6. The beautiful Danish or German curled *Mint*. 7. The round-leav'd spiked wild *Mint*. 8. The great roundish-leav'd marsh or Water *Mint*. 9. The great round-leav'd Marsh *Mint*, with variegated leaves. 10. The hairy verticillate field *Mint*. 11. The rounder-leav'd verticillate field *Mint*, with an aromatic smell. 12 The spiked *Mint*, with variegated leaves. 13. The narrow-leav'd spiked *Mint*. 14. The smooth narrow-leav'd wild *Mint*, with rugged leaves, and a strong scent. 15. The long blackish-leav'd less hairy wild *Mint*. 16. The common thick spiked pepper *Mint*. 17. The long-leav'd horse *Mint*. 18. The longer-leav'd water *Mint*. 19. The water *Mint*, commonly called *Pennyroyal*. 20. The common white-flowered *Pennyroyal*. 21. The water *Mint*, called by many authors *male Pennyroyal*. 22 The smallest woolly water *Mint*. 23. The savory-leav'd water *Mint*. *Tourn.* Inst. p. 189. See the article MINT.

MENYANTHES, *Buckbean*, in botany, the name of a genus of plants, the characters of which are these: The flower consists of one leaf, is funnel-shap'd, and divided into several segments at the edges. From the cup there arises a pistil, which is fixed in the manner of a nail to the hinder part of the flower, and afterwards becomes a fruit or shelly case, usually of an oblong figure, bivalve, and full of small roundish seeds.

The species of this plant, enumerated by Mr. Tournefort, are these: 1. The broad-leav'd trifoliate marsh *Menyanthes*, called by many writers, *Trifolium palustre*, and by us, *Marsh Trefoil*, or *Buckbean*. 2. The narrow-leav'd trifoliate marsh *Menyanthes*. And 3. The American white-flower'd *Menyanthes*, with leaves like those of the water lilly. *Tourn.* Inst. p. 117.

The characters of *Menyanthes*, according to Linnæus, are these: The cup is a perianthium consisting of one leaf, divided into five segments at the end, and is placed erect, and remains

remains after the flower is fallen. The flower consists of a single petal, in form of a short cylindric and somewhat open-mouth'd tube. The rim beyond the middle is divided into five segments, the jags being open, obtuse, bent backward, and covered with a woolly hairyness. The stamina are five short and tapering filaments, and the antheræ are acute, bifid at the bases, and erect. The germen of the pistil is of a conic form; the style is cylindric, and nearly of the length of the flower; and the stigma is bifid and compressed. The fruit is an oval capsule, containing only one cell, and surrounded with the cup. The seeds are very numerous, small, and of an oval figure. *Linnæi* Gen. Plant. p. 64.

MENTZELIA, in botany, the name of a genus of plants, the characters of which are these: The perianthium consists of one leaf, divided into five expanded segments. These are lanceolated and deciduous, and terminate in a very long germen. The flower consists of five ovated petals, which stand expanded, and are somewhat longer than the segments of the cup. The stamina are numerous erect setaceous filaments; the antheræ are simple; the germen of the pistil is of a cylindric figure, and is extremely long, and stands under the cup; the style is setaceous, and of the length of the flower; the stigma is simple; the fruit is a long capsule, of a cylindric clavated form, containing only one cell, in which there are lodged numerous small and roundish seeds. *Linnæi* Gen. Plant. p. 236. *Plumier*, Gen. 6.

MERCATORUM *Festum*, among the Romans, a festival kept by the mercantile people on the ides or 15th of May, in honour of Mercury, to whom they sacrificed a sow; then sprinkling themselves with the water of a fountain called *aqua mercurii*, they prayed the god to prosper their trade. *Danet*, in voc.

MERCURIALIS, *Mercury*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the apetalous kind, consisting only of a number of stamina placed in a cup. These flowers are barren, and the embryo seeds appear on other plants of the same species, which have no flowers. These finally become a fruit composed of two capsules, containing a roundish seed.

The species of *Mercurialis* enumerated by Mr. Tournefort, are these: 1. The testiculated *Mercury*, commonly called the male *Mercury*. 2. The spiked *Mercury*, commonly, but improperly called, the *female Mercury*; this being truly the male, and the testiculate the female, those testicles containing the seeds. 3. The mountain testiculate *Mercury*, called *Cynocrambe*, or *Dogs Mercury*. 4. The spiked cynocrambe, or dogs *Mercury*. 5. The shrubby hoary testicu late *Mercury*, called *Phyllon*. 6. The spiked *Phyllon*, or shrub hoary *Mercury*. 7. The Portugal shrub almond-leav'd testiculate *Mercury*. 8. The spiked almond-leav'd shrub spiked *Mercury*. 9. The round-leav'd three-mouths *Mercury*, the male and female kinds. *Tourn.* Inst. p. 534.

Mercurialis is of an emollient nature, and eaten in the manner of spinach, which, when cultivated in a garden, it greatly excels. If eaten largely, it opens the bowels. A cataplasm of the leaves is much recommended in pains of the limbs, in tumours, and even in ulcers, which it cleanses and disposes to heal. Poor people in country places use it as a cataplasm for the rheumatism, and even for the gout, with success. In the shops, it is chiefly kept as an ingredient in decoctions for glysters.

MERCURIFICATION, in metallurgic chemistry, the obtaining the *Mercury* from metallic minerals in its fluid form. For the effecting this, those who have been engaged in these researches have proposed three methods. The first is by means of a certain mercury, so prepared as to have a dissolving power, by which it could take up the mercuries of metals in the same manner as water dissolves salt from ashes. The second is by means of certain regenerating salts, such as sal armoniac, which are to detain the more earthy parts of metals, and leave their mercuries separate or separable from them by sublimation or otherwise; and the third method is by means of a large lens or burning-glass, in the focus whereof if any metal be applied, its mercurial part is said to separate and go off in fume, which when collected and condensed, appears to be running mercury. *Shaw's* Lectures, p. 160. The first of these methods would be very easy, if the proper mercury were to be readily produced; the second is extremely laborious, and requires much patience and reiteration. But the third seems easy enough, and practicable to advantage, when a glass of three or four foot in diameter is at hand, the sky serene, and the sun shines strong.

MERCURY (*Cycl.*) — The manner of separating *Mercury* from its ore, when not sulphureous, is this: Take a pound of the ore beat to powder; this with the assayer must stand for one centner; put this into a glass retort, coated half way to its neck, which must be long, and turned back with such declivity, that a glass recipient may be applied perpendicularly to it. The retort must be of such a size, that the belly of it may be filled nearly two thirds with the ore; and must be placed so that nothing of the fluid, adherent to the neck of it, may fall into the cavity of the belly, but that the whole may run forward into the recipient, which must be filled with cold water: This must be so placed as to receive the nose of the retort about one half inch into the water. The joints need not be luted. *Cramer's* Art of Assaying, p. 350.

Let the retort be surrounded with burning coals, placed at a distance, lest it burst; by degrees bring the coals nearer, and at length close to the retort; add fresh charcoal, and make it slightly red hot. When this fire has been continued an hour, take off the recipient, first striking the neck of the retort to throw off the loose drops that may hang there; and in the bottom of the water you will find the *Mercury*. This process may be also performed in a sand heat; but the bottom of the retort must touch the bottom of the vessel that contains the sand, and that be made red hot. The *Mercury* is to be separated from the water by filtration.

The supposition of a sympathy between *Mercury* and gold has been the great basis of the attempts of the alchemists of all times, toward the making gold of it. But if they mean that the common *Mercury* has this sympathy with gold, the contrary is proved by that remarkable process, in which it appears that *Mercury* will incalesce with that metal. If they mean that *Mercury* which they call the seed of metals, it is hard to offer any thing in argument against it, this being a sort of ideal substance which no body has yet seen. It is much disputed by the alchemists, whether there be or be not any such thing as *Mercury* that will heat or incalesce with gold, or produce a sensible heat in the mass, on being only simply mixed with that metal reduced to fine parts. It has been said by some, that those *Mercuries* which they call *Mercurii Corporum*; that is, such as have been extracted from the compleat metals by certain processes, which they keep as inviolable secrets, will incalesce on the mixture with gold; and on this they build their processes. But the negative part of the question is more generally maintained, the famous *Mercuries* of metals being held as non-entities with them; and even the searchers after transmutation of metals have in general acknowledged, that they themselves never saw any such incalescence of *Mercury* with gold, though they had heard others speak of it as a thing they had seen. A *Mercury*, however, was some years ago produced before the Royal Society, which in the hands of the president himself, on the fairest trial, did incalesce with that metal. Phil. Transf. N°. 122.

Among the several methods recommended for the fixing this fluid metal into solid silver, oil of talc, and oil of the human fæces, are the most strongly affirmed to be the infallible mediums. The first of these which has been so much misunderstood, by reason of its name, as to be searched for in the stone talc, is truly an oil prepared from the flowers of zink. See the article *Oil of* TALC.

The other is required to be clear and colourless as water, and without any ill smell. These were qualities so difficultly to be found in an oil of that fætid matter, that both the one and the other of these oils were looked upon by many as impracticable processes. But after the first had been made by two or three chemists, Mr. Homberg at length hit upon the last, but without finding any the least tendency to such an effect in it, or any change at all produced by it on *Mercury*, after ever so long digestion, or ever so many processes. Mem. Acad. Par. 1711.

If *Mercury* be dissolved in aqua fortis, so that the solution be clear and total, and if whilst it is yet warm some lead filings be poured in by degrees, the lead will be precipitated into a white powder, and the *Mercury* reduced to a mass of running quick-silver. *Boyle's* Works abr. vol. 1. p. 318.

Mercury may be dissolved in vegetable acids. This is done by reducing it to a calx by a long digestion. A scruple of this calx may be dissolved in an ounce of distilled vinegar, in a boiling heat. The solution being filtred and exposed to the cold, will in part be changed into fine crystals. This calx dissolves likewise in the juice of lemons, rhenish wine, and other vegetable acids.

But a precipitate of *Mercury* made from its solution in aqua fortis, by means of oil of tartar *per deliquium*, and well edulcorated by boiling water, is more easily dissolved in distilled vinegar. It may even be dissolved cold without digestion. *Marggraf*. in Mem. de L'Acad. de Berlin, 1746.

Boerhaave has observed, 1. that quicksilver, however well purified, yields always a soft black powder, of a sharp brassy taste, when long exposed to violent conquassation, or to a degree of heat, twice as great as that of animals. 2. Heat, near as strong as what is necessary for distilling quicksilver, changes the greater part of *Mercury*, if not all of it, into a heavy, shining, red, friable powder, of a sharp nauseous taste, which long and violently disorders the human body, and disposes it to excretions. 3. The fluid quicksilver remaining after this red powder is separated, is more fluid, and of less specific weight than common *Mercury*. 4. All the black, and near the whole red powder, can be brought into the former fluid state, by a more intense heat; and this revivified quicksilver enjoys all the properties of common *Mercury*.

The experiments on *Mercury* above-mentioned were sent by Boerhaave to the Royal Society. He sent an account of others to the Royal Academy of Sciences at Paris. The conclusions from these experiments are, that he could not change quicksilver into any other metal, and that no quicksilver was to

to be got from lead or tin. See Mem. de l'Acad. Royal. des Scienc. 1734.

Mercury diffolved by rubbing it ftrongly with any chemical oil, or with Venice turpentine, has been given to the quantity of a fcruple, half a dram, or two fcruples in a day. Such pills keep fome people's belly open, others they purge, and a gentle ptyalifm has fometimes been occafioned, nay, a high falivation has been raifed by them. See Medic. Eff. Edinb.

Dr. Dover, in his Phyfician's Legacy to his country, having recommended crude *Mercury* or quickfilver as a moft beneficial medicine for feveral difeafes, it had for fome time a great run at London, which occafioned the writing a great many pamphlets for and againft it. Dr. Cheyne alfo greatly recommends this medicine in his treatife, entituled, *The Rational Method of curing Difeafes.*

The authors of the medical effays of Edinburgh affure us, that though fome they knew had taken an ounce or two of crude *Mercury* each morning for feveral weeks, yet they knew no inftance of its encreafing any of the fenfible evacuations; but they have been told, that fome who ufed it thus, had paffed fome of it with their urine, and that the hands of others, taking this medicine, had tinged their fnuff-boxes, &c.

But we have an account of the effects of crude *Mercury* on a perfon who had the advice of his phyfician for the taking it, in a remarkable cafe recorded in the Philofophical Tranfactions, about the time when Dr. Dover had brought it into fuch general ufe; and as the effects of it, in this cafe, may ferve to caution people as to the ufe of it, it may be proper to give the fubftance of it, which is this: A perfon had long been fubject to great difficulty in going to ftool, for which he at length took feveral ounces of crude *Mercury* at different times, but without relief. Upon the opening of the abdomen there iffued out a great quantity of wind, before the ftomach or guts were wounded. The ftomach was empty, and its inner coat violently inflamed. The fmall guts were, in many places, fouled with a black powder refembling Æthiops mineral, and in feveral parts of them were found fmall globules of quickfilver. The black powder was doubtlefs the quickfilver altered into a fort of æthiops in the body. The colon was inflamed and diftended, and contained fix quarts of liquid excrement, among which was a great deal of crude *Mercury*, and of the fame black powder. This gut alfo was inflamed on the outfide, and had formed an abfcefs where it adhered to the omentum; the other guts in contact with this part alfo fhared this diforder. In the lower part of the colon the coats became fchirrous, and the paffage was very fmall. Some of the valves were alfo become fchirrous, and obftructed the paffage, and a fmall plumb-ftone was found buried in the villofe coat of this inteftine. This had alfo formed a fmall abfcefs, which difcharged itfelf into the pelvis. What part of thefe fymptoms was owing to the taking the quickfilver is eafy feen, and fuch effects may be guarded againft for the future, by obferving the ftate of the patient before it is given. Philof. Tranf. N°. 442. p. 295.

Chemifts having obferved that fome fimple preparations of antimony and *Mercury* had furprizing effects in the cure of obftinate diftempers, employed their art to change thefe Herculean medicines into various fhapes, to feparate their noxious and ufelefs parts, and to combine their active principles. To thefe labours are owing the butter and cinnabar of antimony, *Mercurius vitæ*, bezoard mineral, folar, lunar, jovial, and feveral other preparations, on which the moft exorbitant encomiums have been lavifhed. But with all this care, many of thefe remained unactive, and others incorrigible, and unfit for ufe. However it is certain that thefe two minerals, properly combined, have wonderful effects. We have, in the medical effays of Edinburgh, a preparation of Dr. Plummers, which is much recommended from the experience of its effects. See PLUMMER'S *Æthiops.*

Mercury is often ufed in anatomical preparations, efpecially for fuch parts that do not eafily retain air, as the lungs, or fpleen, and glans penis. See *Monro* in Med. Eff. Edinb. vol. 3. art. 10. But it is to be obferved, that the quickfilver does confiderable damage to the fmall cells of the lungs and glans.

Befide the numerous other phænomena attending this remarkable mineral, the light it gives when fhaken in a glafs tube, which proceeds from electricity, is not to be omitted.

If *Mercury* be enclofed in a glafs tube, clofe ftopped, that tube is found, on being rubbed, to give greatly more light than when it had no *Mercury* in it. When this tube has been rubbed, after raifing fucceffively its extremities, that the *Mercury* might flow from one end to the other, one fees a light creeping in a ferpentine manner all along the tube; that is to fay, the *Mercury* is all luminous. The *Mercury* being made to run along the tube afterwards without rubbing it, was found to emit fome light, though much lefs than before; this proves that the friction of the *Mercury* againft the glafs, in running along, does in fome meafure electrify the glafs, as the rubbing it with the hand does, only it is in a much lefs degree. This is more plainly proved by laying fome very light down near the tube, for this will be attracted by the electricity raifed by the running of the *Mercury*, and will rife to that part of the glafs along which the *Mercury* runs; and it is very plain from this, that what has been long known in the world under the name of the *phofphorus* of the barometer, is not a phofphorus, but merely a light raifed by electricity, the *Mercury* electrifying the tube. Phil. Tranf. N°. 484.

If *Mercury* be put into large exhaufted tubes, and thefe afterwards rubbed to excite their electricity, it is obferved that they give, on all fides, rays of a very bright and very lively light.

Calcin'd MERCURY, *Mercurius Calcinatus*, a new and more expreffive name for the preparation of *Mercury*, commonly called *precipitate per fe.* It is made by fetting purified quickfilver for feveral months in a fand heat, in a glafs veffel with a broad bottom, and opening it to the air by a fmall hole, till it is reduced to a red powder.

The quickfilver muft have a communication with the external air, as is neceffary to the calcining of all the metals. This opening is beft made, not as in the common bolt-heads, but at the lower end of a ftem, going into the body of the glafs; that if the quickfilver rife with the heat, it may not, by afcending into the ftem, be removed out of the heat that is to calcine it. *Pemberton's* Lond. Difp. p. 225.

Coralline MERCURY, *Mercurius Corallinus*, the name given in the London Difpenfatory to a preparation of *Mercury*, commonly known by the name of *arcanum corallinum.* It is prepared in this manner: Pour upon the red corrofive *Mercury*, commonly called *red precipitate*, thrice its weight of rectified fpirit of wine, digeft them together in a gentle heat for two or three days, often fhaking the phial, then fet fire to the fpirit, and continue ftirring the powder till the fpirit is burnt away. *Pemberton's* Lond. Difp. p. 227.

This operation proceeds upon the principle of fpirit of wine dulcifying acid fpirits.

Oil of MERCURY, the name given by the chemifts to a preparation of *Mercury* in a fluid form, by means of a ftrong acid. The preparation is this: Calcine *Mercury* with oil of vitriol to a dry fnowy calx; fuffer it to cool, then put it into a glafs, and pour upon it an equal quantity of oil of vitriol; let this boil away almoft to a drynefs, carefully avoiding the poifonous fumes; then increafe the fire, and by degrees reduce it to a drynefs again; which is, in this ftate, a very difficult and tedious tafk. When the powder is dry, put the fame quantity of oil of vitriol again to it, and proceed as before: At length it will fcarce dry by means of ever fo long or ftrong a fire, but only ceafe flowing freely, and become fomewhat rigid like a fixed oil. It is then highly fharp, cauftic, and not to be touched, like the *ignis gehennæ* of Paracelfus. By this means the *Mercury* is fo fixed with the oil of vitriol, as not to be evaporated, or fly off, by the action of a very violent fire. *Boerh.* Chem. p. 317.

By this procefs we fee the method of impregnating, faturating, and incerating metals by acids to any degree, and alfo of fixing, in a great degree, volatile *Mercury* by them; but no metal is hence to be expected, for in whatever manner *Mercury* is fixed with acids, it is always recoverable again in its priftine ftate, by grinding it with twice its weight of iron filings, and diftilling in a glafs retort, with the greateft degree of a fand heat. Ibid. p. 320.

Corrofive Sublimate of MERCURY. Mr. Boulduc defcribes an eafy manner of making corrofive fublimate. He pours equal quantities of quickfilver and dephlegmated oil of vitriol into a retort, then draws off part of the acid, which does not incorporate with the quickfilver; the fire is continued till the white mafs of diffolved *Mercury* is dry, when he fpeedily mixes it with equal parts of dried fea falt, and fublimes it in the common way.

MERCURY, *Mercurialis*, in botany and medicine. See the article MERCURIALIS.

MERCURIUS *Dulcis*. *Mercurius Dulcis* in large dofes, with cinnabar of antimony, is recommended in nervous difeafes, palfy, hemiplegia, epilepfy, and apoplexy. Med. Eff. Edinb.

Mr. Dictericus gives us thefe rules for knowing whether fublimate is fufficiently edulcorated in making *Mercurius Dulcis*. If after rubbing the *Mercury* on gold, the gold becomes only pale, and not white, the *Mercury* is dulcified enough; or if fweet *Mercury* becomes black when mixed with lime-water, it is fit for ufe; but if either the gold becomes white, or the *Mercury* is of a brown or yellow colour, after mixing with lime-water, it is not fufficiently dulcified. Commerc. Norem. 1737. hebd. 29. § 2.

MERCURIUS *Emeticus Flavus*, a name given in the late London Difpenfatory to the mercurial preparation commonly known by the name of *turbith mineral. Pemberton's* Lond. Difp. p. 228.

MERCURIUS *Vitæ* may, according to Mr. Boyle, be moderated in its evacuating quality, by continually ftirring it in a flat glazed earthen veffel, over a fire, till it emits no fumes, and turns of a grey colour; and he thinks this is the *Mercurius Vitæ purgans* fo often mentioned by Riverius. *Boyle*, Works Abr. vol. 1. p. 74.

Mr. Godfrey obferves, that what is called *Mercurius Vitæ*, prepared of fublimate mercury and antimony, has no *Mercury* in it, but is the reguline part of the antimony, with the acid of the fublimate; and what remains is the *Mercury* formed

formed into cinnabar by the fulphur of the antimony. Mifcel. vere Util. p. 58.

MERCY, in law, is ufed for the arbitrament of the king or judge, in punifhing offences, not directly cenfured by law. *Blount, Cowel.*

MERDESENGI, in the materia medica of the Arabians, a name given by Serapio to litharge. Avifenna calls this fubftance *mardac*, and it has been erroneoufly fuppofed from this, that *mardac* and *Merdefengi* were not the fame fubftance; but this is a falfe conjecture. See the article MARDAC.

MERDIVORÆ, the *Dung Eaters*, in natural hiftory, the name given by authors to feveral flies which feed on excrements of different animals. Of thefe there are three kinds very common among us, the *coprophagos*, which is of a dun colour, with a reddifh head, and a white ftreak along the middle of it. The red *dung-fly*, which has filvery wings, a red body, and black fhoulders. And 3. The green one, which is of a very glittering hue, and has filvery wings.

MERGANSER, in zoology, the name of a large water fowl, called in Englifh, the *Goofander*, and by fome authors, the *Harle*. See MERGUS.

Its common weight is four pounds, its body is oblong, and its back broad and flat. Its head, and the upper part of its neck, is in the male of a fine bluifh or greenifh black, very bright and fhining; the lower part of its neck is white, and the middle of the back, part of the neck and part of the wings are black, the reft are grey; the tail is grey; all the under part of the body is of a faint afh-colour. The beak is near four inches long, hooked and pointed at the end, and ferrated, and is part black and part red. The feet and legs are red; the three fore toes are joined by a membrane, but the hinder one loofe, yet that is encreafed in breadth by a fmall membrane. Its head feathers ftand loofe, and make the head look larger than it is; but it has not, properly fpeaking, the creft which many of the birds of the fame genus have. *Ray*, Ornithol. p. 253.

This is the figure of the male *Merganfer*; the female differs fo much from this, as to be not only efteemed a different bird by the common people, but even defcribed as fuch by authors. It is called by our people the *Dundiver*, or *Sparling Fowl*, and by authors, *mergus cirratus longiroftер*, the long-beak'd crefted diver. The great difference, however, is, that the female is of a fomewhat reddifh brown on the head, and has a creft. See the article DUNDIVER.

MERETRIX, among the Romans. The *Meretrices* were the better fort of curtezans, and differed much from the *proftibulæ*, or common proftitutes, who had bills or infcriptions, *tituli*, over their doors, and were ready at all times to entertain their cuftomers; whereas the *Meretrices* entertained none but at night.

The *Meretrices* were diftinguifhed from the matrons by their drefs, being obliged to wear the *toga* and fhort tunics, like thofe of the men; whereas the matrons wore the *ftola*, which was a garment that reached down to their feet, as did likewife their *palla*, or outer robe. *Pitifc.*

MERGEN, a word ufed by fome of the chemical writers to exprefs coral.

MERGUS, in the Linnæan fyftem of zoology, the name of a diftinct genus of birds, of the order of the anferes. The diftinguifhing characteriftic of this genus is, that the beak is fomewhat cylindric, and has a crooked point. *Linnæi* Syft. Natur. p. 46.

The characters of this genus, according to Mr. Ray, are thefe: The feet are webbed, the three fore toes being connected by a membrane, but the hinder toe is left loofe. The beak is narrow, hooked at the end, and ferrated.

Of this genus are the *merganfer*, or goofander, the female of which fpecies is called the *dundiver*. 2. The *albellus* of Aldrovand. 3. The *ferula* of the Venetians. Which fee under their feveral heads. And laftly, the *Mergus Rhein*; commonly called fimply by the name *Mergus*. *Ray*'s Ornithol. p. 254.

This laft is of the fize of a duck, and fomewhat refembles that bird in fhape. It is all over very beautifully variegated with black and white. Its beak is black; and its belly is variegated with grey, with the black inftead of white. Its tail is black; its legs brown, and the membrane of its feet black. Notwithftanding that this feems defcribed as a different fpecies by authors, there is much room to fufpect that it is the fame with our *albellus*. *Aldrovand.* de Avib. T. 3. p. 275. *Ray*'s Ornithol. p. 254.

MERGUS *Albellus Dictus*, in zoology, the name of the common *Mergus*, called *Mergus cirratus major*, the greater crefted diver, and *Mergus Rhein*, the diver of the Rhine, and commonly known in England by the name of the *fmew*.

Its common weight is a pound and a half, and its beak is an inch and half in length. Its head and neck are white, except that it has a large black fpot ending in a point, and furrounding the bottom of that tuft of feathers which hang from the back part of the head, and are what authors call the *cirrus* or *creft*; and another oblong black ftreak which runs from the angles of the beak to the eyes. Its throat, breaft, and belly, are all fnow white, and its back all over of a fine deep black; but its fhoulder feathers, which are long and hang over the back, in part on each fide, are white. Near the joining of the wings to the back, there are two or three arched black lines; and on the lower part of the neck there is another line, making a fort of ring of the fame colour. The wing feathers are partly black, partly white. Its beak is of a lead-colour'd grey, large at the bafe, and tapering to a fharp hooked point. In the female the head is reddifh, the throat is white; but there is a fort of circle of a brownifh colour on the breaft. Its upper part alfo is almoft all grey, and it has no creft. It feeds on fifh, and is very common on our coafts. *Ray*'s Ornithol. p. 254.

MERGUS *Cirratus Minor*, in zoology, a name by which Gefner calls the *capo negro*, a fpecies of duck, called in Englifh, the tufted duck, from its having a tuft of feathers, of an inch and half in length, hanging from the back of its head. *Gefner*, de Avib.

MERIDIONAL (*Cycl.*)—MERIDIONAL *Parts*. To find the *Meridional Parts* to any fpheroid, with the fame exactnefs as in a fphere.

Let the femi-diameter of the equator be to the diftance of the focus of the generating ellipfe from the center as m to 1. Let A reprefent the latitude for which the *meridional* parts are required, s the fine of this latitude, the radius being unit; find the ark B, whofe fine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B from the common tables; fubtract this logarithmic tangent from 10.0000000, or the logarithmic tangent of 45°; multiply the remainder by $\frac{7915.7044678978}{m}$, &c. and the product fubtracted from the *meridional* parts in the fphere, computed in the ufual manner for the latitude A, will give the *meridional* parts expreffed in minutes for the fame latitude in the fpheroid, provided it be oblate.

Example: If $mm : 1 :: 1000 : 22$, then the greateft difference of the *meridional* parts in the fphere and fpheroid is 76.0929 minutes: In other cafes it is found by multiplying the remainder above-mentioned by 1174.078.

When the fpheroid is oblong, the difference of the *meridional* parts in the fphere and fpheroid, for the fame latitude, is then determined by a circular ark. Phil. Tranf. N. 461. Sect. 14. See alfo *Maclaurin*'s Fluxions, art. 895—899.

Mr. Murdoch has folved this problem by infinite feries, and has computed a table of *meridional* parts for an oblate fpheroid, fuch as is mentioned in the foregoing example. See his Treat. intituled, *Mercator's Sailing applied to the true Figure of the Earth*, Lond. 1741. 4°.

MERIS, in mufic, an appellation given by Mr. Sauveur to the forty third part of an octave. See Mem. Acad. Scienc. 1701. The word is Greek, μερις, a part.

MERLANGUS, in ichthyography, a name given by Bellonius, and fome other authors, to a fmall fpecies of whiting or *afellus mollis*, called by the Venetians, *mollo*, and by fome other nations, the *capelan*. *Willughby*'s Hift. Pifc. p. 171. See the article MOLLO.

MERLANUS, a name given by fome writers in ichthyography to the common whiting or *afellus mollis five albus*. *Rondelet*, de Pifc. p. 97. See the article WHITING.

MERLUCIUS, in zoology, the name of a fifh commonly called the *hake*, and by fome authors the *afellus alter*.

It is a moderately large fifh, growing to two foot or more in in length, and refembling the common pike in figure, from whence it has its name, *Merlucius*, *quafi maris lucius*, the fea pike. It in fome meafure refembles the common whiting in colour, the back being of a pale greyifh hue, and the belly white. It is covered with fmall fcales. Its head is broad and flat, and its mouth very wide, as in the frefh water pike. The jaws are both, but efpecially the lower, armed with long fharp teeth, with others fmaller and fhorter between them. The eyes are large, and their iris of a fine yellow. It has two fins on the back, the firft near the head, the other not far diftant from it, and fo long as to reach nearly to the tail. Its gill-fins are narrow, and its belly-fins are placed very high. Its tail is not forked. It is caught in the Englifh and other feas, and is a valuable fifh for the table. *Ray*'s Ichthyogr. p. 174.

MEROPS, in zoology, the name of a bird called alfo *apiafter*, and in Englifh the *bee-eater*.

It refembles the king-fifher in fhape, and is of the fize of a black-bird. Its beak is long, black, and a little crooked, and the irifes of its eyes of a fine red. Its head is long and large. The feathers growing at the infertion of the upper chap are of a bluifh green; but thofe on the middle of the head are white; the crown, however, a little backwarder is of a reddifh brown, fometimes with a flight admixture of green; and there runs on each fide a black line from the angle of the beak through the orbit of the eyes; its neck and fhoulders are green, but with a caft of rednefs; and its belly and breaft are blue. The tips of the long wing feathers are blackifh, and the reft are variegated with a bright green and a fine orange colour. Its tail is of a fine blue, and the two middle feathers of it are longer than any of the others. Its legs are very fhort and thick, and are of the fame form with the

the kingfisher's. It is very common in Italy, and extremely so in the island of Crete; but is not known in England. It feeds on bees and other insects, and sometimes on seeds. See Tab. of Bird, N°. 17. *Ray's* Ornithol. p. 102.

MEROS, in zoology, the name of a very large American fish, growing to five or six feet long, and called by the Brasilians, *cugupu-guacu.* Its head is very large, and its mouth wide and toothless. Its eyes have a black pupil and a yellow iris. It has five fins, one running the whole length of the back, and reaching nearly to the tail; the anterior part of this is narrow, and armed with small but sharp spines; the other part is broader, and sustained by softer rays. Behind the anus is one like the hinder part of that on the back, and two others behind the gills, which are large and broad. The tail fin is very large and broad, and much more so at its extremity than at its origin. Its scales are small. Its head, back, and sides, are of a brownish grey, and its belly white. It is accounted a well tasted fish. See Tab. of Fishes, N°. 53. *Ray's* Ichthyography, p. 303.

MERULA, in ornithology, the name of the black-bird, a bird of the turdus or thrush kind, of which there are several species. 1. The common kind, well known in our hedges. 2. The kind called the *passer solitarius*, or solitary sparrow. See PASSER. 3. The *Cæruleus*, of which there are two kinds. See CÆRULEUS. 5. The Brasilian *Black-bird*, remarkable for the shortness and crookedness of its beak, and for its remarkably beautiful colours. Its tail and wings are black, and the rest of its body of a fine beautiful deep red. Its legs and feet are black, or of a brownish grey. Its wing feathers also have some slight variegations of red. 6. The *Merula Rosea*, or rose-coloured black bird; this is smaller than the common kind, and its back, breast and wings are of a pale red or damask rose-colour. Its wings and tail black. 7. The red-breasted Indian *Black-bird*, called by the Brasilians *jacapu.* See JACAPU. 8. The *Merula Torquata*, or ring amzell. See AMZELL. Beside these there is the *Merula Montana*, or common amzell: And the *Merula Bicolor*: And two other birds, called *Merula Congeneres* described by Aldrovandus, but not now known. See Tab. of Birds, N°. 29, 30. and *Ray's* Ornithol. p. 140.

MERULA, in ichthyology, the name of a sea fish of the turdus or wrasse kind, of a short aod flat figure, and all over of a dull and dead bluish black. The back, sides, and belly, are all of this colour, as are also even the fins and tail. It is a fish not much esteemed, being of an insipid watery taste, but is sold among the poorer sort in the Italian markets. *Rondelet.* de Pisc. L. 6. c. 5. p. 172.

MERULA *Aquatica*, the name of a bird, called the *water ouzel* in English.

It is about the size of the common black-bird, but has a shorter body, and a thicker neck. Its beak is strait, sharp, and black, and its head, and the upper part of its neck, are of a brownish black. Its back and wings are variegated with black and grey; its throat and breast are of a snow white; but the belly toward the tail is black; its tail is short, and it is very thick feathered, as are in general all the water birds. It frequents waters, and is very common in many parts of Germany, nor much less so in the northern counties of England. It feeds on fish, and sometimes on insects, and though not a web-footed fowl, will sometimes dive under water after its prey. *Ray's* Ornithol. p. 104.

MERULA *Fluviatilis*, in ichthyology, a name given by Schoneveldt, and some other writers, to the common tench. These are whimsical and arbitrary names, and express nothing. Artedi has much better distinguished the fish, having taken away even its generical name, and reduced it to the *cyprini*, of which genus it is evidently a species: He has called it the *black mucous cyprinus*, with an even, not forked or invected tail. This is a name by which it can never be mistaken. *Artedi* Gen. Pis.

MERULA *Saxatilis*, a name given by some to the *tordo marino.* See the article TORDO *Marino.*

MERZENIUS, in botany, a name used by some authors for marjoram. *Ger.* Emac. Ind. 2.

MES-AIR, in the manege, is a manege half *terra a terra*, and half corvet. See the articles TERRA *a Terra*, and CORVET, *Cycl.*

MESANGIA, in natural history, the name of a bird common in France and Italy; it is of the size and shape of the ficedula, and differs from it in very little, except the having a black spot upon the head. This seems to be the *melancoryphos* of the antients, who supposed, as many do at this time, that the ficedula changed into this bird. The ficedula, or fig-eater, comes into the gardens in France only at the time when the figs, which are its proper food, are ripe: These it devours in an insatiable manner, and as soon as it has done with them, goes away again. Soon after this the *Mesangia* or black cap appears, and is supposed to be the same bird, with the addition of this beautiful ornament. The antients were very fond of this imaginary change of one bird into another; and Aristotle tells us that the upupa is the same bird with the cuckow, only changed in the colour and disposition of its feathers. Æschylus tells us in the same manner, according to the opinion of his times, that the cuckow sings all the summer, and after that disappears; and that soon afterwards it comes again in a new form, with a plume upon its head, and is called the *upupa.*

MESAZONTES, Μεσαζοντες, officers under the emperors of Constantinople. See the article MEDIATOR.

MESE, in the Greek music, was the ultimate note of the meson tetrachord, and answers to Guido's *a la mi re. Wallis*, Append. *Ptolem.* Harm. p. 157. See the article DIAGRAM.

MESEMBRYANTHEMUM, in botany, the name by which Dillenius, Linnæus, and others, have called the plants usually named *Ficoides. Linnæi* Gen. Pl. p. 250.

MESENTERICA *Febris*, a name given by some authors to a peculiar kind of acute fever, called by our Sydenham, *nova febris* in a peculiar treatise; and by Heister more properly the stomachic or intestinal fever. See the article INTESTINALIS *Febris.*

MESERA, a name given by some medicinal writers to the Alexandrian tutty.

MESENTERIC (*Cycl.*)—MESENTERIC or MESERAIC *Arteries.* Ruysch [a] painted the *meseraic* arteries and veins as having different courses in the distribution of their branches in the intestines. Albinus [b] attributes this mistake to Ruysch's having injected the arteries at one part of the intestines, and the veins at another; and by a figure representing the internal cellular membrane of the ilium, with both arteries and veins injected, shews their courses to be the same.—[[a] Adv. Dec. 3. Tab. 1. fig. 4, 5, 6, 7. [b] Differt. de Arter. & Ven. Intestin. ap Med. Ess. Edinb.] See the article MESENTERIC, *Cycl.*

MESIRE, a name given by Avisenna to a distemperature of the liver, attended with a sense of heaviness, tumour, inflammation, and pungent pain, and always with thirst, a dry mouth, and a parched black tongue.

MESITICUM, among the Romans, a toll paid for a place to sell goods in the forum. *Pitisc.* in voc.

MESMARCHURES, in the manege. See the article PASTERN.

MESOCHORUS, Μεσοχορος, among the antients. The *mesochori* were musicians who presided in concerts, and by beating a desk in a regular manner with their feet, directed the measure of the music. For this purpose in the theatre they wore wooden clogs on their feet, that they might be better heard, which were called by the Greeks, *Crupezia. Hofm.* Lex. in voc.

MESOCHORUS, among the Romans, was also used for a person in public assemblies, appointed to give the signal for acclamation at the proper time, that all might join in it at once. *Pitisc.* in voc. See the article ACCLAMATION.

MESOCUROS, Μεσοκουρος, in antiquity, an actress in tragedies who had the middle part of her head shaven: But others think that *Mesocuros* signifies a girl, or very young woman. *Hofm.* in voc.

MESOGLOSSI, a name given by some writers to the muscles of the tongue, more usually called by anatomists, the *Genioglossi.*

MESOPYCNI, Μεσοπυκνοι, in the antient music, was an appellation given to such chords as formed the middle notes of the spissa. There were five *Mesopycni* in the scale. See the articles PYCNI and SPISSUM.

MESORO, in ichthyology, a name given by Salvian to that fish which we call the butterfly-fish, the blennus or belennius of other authors. It is distinguished by Artedi by the name of the *blennus*, with a furrow between the eyes, and a large spot in the back fin. Salvian has taken his name from the common appellation of this fish among the Italian fishermen. See the article BLENNUS.

MESORO is also used by the Italians for the fish commonly called the *uranoscope* or *star-gazer.* It is a species of the trachini, and is distinguished by Artedi under the name of the *trachinus*, with many beards on the lower jaw. *Willughby*, Hist. Pisc. p. 132.

MESOTHENAR, a flat and nearly triangular muscle, lying between the first phalanx of the thumb and the bottom of the palm of the hand. It is inserted by a very broad basis in the ligament which connects the os magnum to that which supports the thumb. It is likewise inserted along the internal or angular part of that bone of the metacarpus which supports the middle finger, and in the small extremity of that which answers to the index; from thence the fibres contracting to an angle, terminate in a flat tendon of different breadths, which is inserted in that side of the head of the first phalanx of the thumb, which is turned to the hollow of the hand, and in the neighbouring part of the basis of the second phalanx, by means of the second sesamoide bone belonging to that joint. *Winslow's* Anatomy, p. 197.

MESPILEUS *Lapis*, in natural history, a name given to some species of the echinitæ, from their resemblance to the ripe fruit of a medlar. This was a name given them before they were much known, and they were some time afterwards called, from their five lines on the surface, *pentexoche.*

MESPILUS, the *Medlar*, in botany, the name of a genus of trees, the characters of which are these: The flower is of the rosaceous kind, being composed of several petals arranged in a circular form, the foliaceous cup of which becomes afterwards a fruit of a roundish figure, coronated at the end, fleshy,

fleſhy, ſoft, and unicapſular, containing ſeveral ſtones, each having an oblong kernel. See Tab. of Botany, Claſs 21.

The ſpecies of *Meſpilus* enumerated by Mr. Tournefort, are theſe: 1. The common wild *Medlar*, or German *Medlar*, with bay-like, not ſerrated leaves. 2. The greater bay-leav'd *Medlar*. 3. The great bay-leav'd *Medlar*, with an early-ripe, oblong, ſoft, and ſweet-taſted fruit. 4. The great bay-leav'd *Maple*, with a ſoft ſweet-taſted ſmaller fruit. 5. The *Medlar* with a middle-ſized oblong auſtere and ill-taſted fruit, with the corona always cloſed. 6. The parſley-leav'd *Meſpilus*, called the *lazerole*. 7. The double-flowered jagged apium-leav'd *Meſpilus*. 8. The *Lazerole*, with a large deep red and well-taſted fruit. 9. the *Lazerole*, with a ſmaller yellowiſh fruit. 10. The wild ſmall-fruited yellowiſh white *Lazerole*, with a turbinated fruit. 11. The Canada ſervice-leav'd *Meſpilus*. 12. The prickly *Meſpilus*, with pear-like, ſhining, and denticulated leaves, and with very beautiful red fruit. 13. The common apium-leav'd prickly *Meſpilus*, called the white thorn. 14. The common *white Thorn*, with double flowers. 15. The almond-leav'd prickly *Meſpilus*. 16. The barren wild trifoliate apium-leav'd *Meſpilus*, with very ſtrong thorns. 17. The large-fruited wild *Meſpilus*, with ſtrong prickles, and with hairy palmated apium leaves. 18. The roundiſh-leav'd *Meſpilus*, with black ſweetiſh fruit. 19. The roundiſh-leav'd *Meſpilus*, with red fruit. And 20. The American *Meſpilus*, with red fruit, and with broad leaves prickly underneath. *Tourn.* Inſt. p. 644. See the article MEDLAR.

MESSE *da Capella*, in the Italian muſic, is uſed for maſſes ſung by the grand chorus. In theſe, various fugues, double counter-points, and other ornaments, are uſed *Broſſard.*

MESSE *Concertate*, in the Italian muſic, is a maſs wherein the parts reciting are intermixed with choruſſes. *Broſſard.*

MESUA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is permanent, and conſiſts of four ſmall oval leaves. The flower conſiſts of four large hollow and rounded petals. The ſtamina are numerous filaments, of the length of the cup. The antheræ are ſimple. The germen of the piſtil is roundiſh. The ſtyle is ſimple; and the ſtigma indented in four places. The fruit is a roundiſh, pointed, coriaceous capſule, with four longitudinal ſutures. It is compoſed of four valves, and contains four large fleſhy, obtuſe, three-corner'd, and turbinated ſeeds bedded in it. *Linnæi* Gen. Plant. p. 235. *Hort.* Mal. vol. 3. p. 53.

METACAL, an Ægyptian weight, uſed in the weighing of pearls, and conſiſting either of a carrat and a half, or of two carrats. Sixteen of theſe carrats make a dram, each of the carrats weighing four grains, and twelve drams an ounce. *Pocock*'s Ægypt. p. 175.

METACARPIUS, a ſmall very fleſhy muſcle, ſituated obliquely between the large internal annular or tranſverſe ligament of the carpus, and the whole inſide of the fourth metacarpal bone.

It is fixed by a ſmall ſhort tendon to the os orbiculare, and to the neighbouring part of the large ligament of the carpus; from thence its fibres run more or leſs obliquely toward the inſide of the fourth metacarpal bone, in the outer edge of which they are inſerted. The fibres of this muſcle are of unequal lengths, and extend all the way to the articulation of the firſt phalanx of the little finger, with the fourth metacarpal bone; but they have no manner of relation to that finger. *Winſlow*'s Anatomy, p. 194.

METACARPUS (*Cycl.*)—The antient anatomiſts reckoned five bones in the *metacarpus*, including that bone which is now looked upon to be the firſt phalanx of the thumb, the rejecting which from among them, has reduced the number to the four we allow. Theſe bones are all long, thicker at their extremities than in the middle, and of unequal length and bigneſs: The two firſt are ſometimes, though very rarely, equal, and the others leſſen by degrees from them. Anatomiſts, in their deſcriptions, divide each of theſe bones into a middle and two extremities, or into a baſis, body, and head. The baſes of them all are angular, and turned toward the carpus, and their head rounded like condyles, and turned toward the fingers. Both extremities are covered with cartilages, and the heads remain for a long time very diſtinct epiphyſes.

The firſt bone of the metacarpus is longeſt and largeſt, and ſupports the fore finger; its baſis is a little hollow, anſwering to the digital ſide of the os pyramidale of the carpus. On the outer edge there is a ſmall angular notch, and on the cubital edge of the baſis is a ſmall lateral ſide, which is articulated with the baſis of the ſecond bone. The inner edge is terminated laterally by an oblique angle, which is articulated with the neighbouring angle in the baſis of the os magnum; round the baſis are inequalities and depreſſions for the ligaments and articular glands. The outſide of the body of the bone is broader toward the head than toward the baſis.

The ſecond bone of the *Metacarpus* ſupports the middle finger, and has this very peculiar in it, that its baſis is very oblique, terminating at the outer edge by an angular point toward the firſt bone. By the triangular ſide of its baſis it is articulated with the baſis of the os magnum, and by its lateral ſides with thoſe of the firſt and third bones of the *Metacarpus.* The third bone is that which ſupports the ring finger, being leſs than the firſt and ſecond. Its baſis is irregularly triangular, and proportionably leſs than the two former, and by the principal ſide thereof, it is articulated with the firſt half of the ſide of the os unciforme; the ſmall lateral ſides of the baſis join thoſe of the ſecond and fourth bone. The fourth bone ſupports the little finger; the principal ſide of the baſis of this, inſtead of being triangular, as in other bones, is all of an equal breadth, a little oblique, and ſome part of it gently convex, the reſt gently concave, and articulated with the ſecond half of the ſide of the os unciforme; by its lateral ſide it joins the correſponding ſide of the baſis of the third bone, but in a much looſer manner than in the other articulations of that kind. In the oppoſite ſide there is a ſmall tuberoſity. *Winſlow*'s Anatomy, p. 86.

Fractures of the METACARPUS. In fractures of the hand or *Metacarpus*, the beſt method of reducing and replacing the bones, is, to extend the hand upon a ſmooth table, and while an aſſiſtant holds the whole hand evenly in that poſture, the ſurgeon is to replace the bones; and when that is carefully and perfectly done, to ſecure them with a proper bandage. *Heiſter*, Surg. p. 129.

Luxation of the METACARPUS. The four ſmall bones in the palm of the hand are ſometimes luxated from the carpus to which their upper parts are connected; this happens from external violences, not unfrequently, notwithſtanding that theſe bones naturally muſt much reſiſt ſuch a luxation; for the two carpal bones, which are ſeated in the middle between the two external ones, cannot be diſlocated to either ſide, as the two external ones, which ſuſtain the firſt and little fingers, cannot be luxated inwardly, but are very eaſily driven outward; and each of them may be luxated on the fore or back part of the hand; but which ever of theſe happens, the particular diſorder may be diſcovered and examined by feeling and inſpecting, and the cure may be performed by extending the hand on a flat board or table, and replacing with the thumb whatever of the bones have ſtarted from their natural ſituation. *Heiſter*'s Surg. p. 166.

METACHORESIS, a word uſed by Galen to expreſs a receſs of a morbid humour from one part of the body to another, a thing very common in many diſtempers.

METACOE, in botany, a name given by the people of Guinea to a plant, of which they are very fond, becauſe of its virtues as a balſamic and vulnerary. Its leaves, being bruiſed and applied to a freſh wound, cure it. They have alſo another uſe for it, twiſting the dried leaves into a ſort of match for their muſkets. Phil. Tranſ. N°. 232.

METAGITNION, Μεταγειτνιων, in chronology, the ſecond month of the Athenian year. It contained twenty-nine days, and anſwered to the latter part of our July and beginning of Auguſt. The Bœotians called it *Panemus*, and the people of Syracuſe, *Carnius*.

It was ſo called from *Metagitnia*, one of Apollo's feſtivals kept in it. Vid. *Potter*, Archæol. Græc. T. 1. p. 414.

METAL (*Cycl.*)—Experiments on *Metals*, made with the great burning-glaſs at Paris, have proved, that all the imperfect metals, copper, iron, tin, and lead, are compoſed only of two parts, a ſulphur or oily matter, and a more denſe ſubſtance, called their earth, capable of vitrification. That from this oil or ſulphur proceed the opacity, the glittering brightneſs, and the malleability of theſe metals; that this ſulphur or oil ſeems no way different from the oils of vegetables and animals, and that it is the ſame in all the four imperfect *Metals*, and in mercury: That theſe four metals have a different ſubſtance for their baſe, the earth of each vitrifying in a different manner; and that to this is owing their difference from one another. Mem. Acad. Par. 1709.

Specific Gravity of METALS. The ſpecific gravity of *Metals* can never be very exactly determin'd, for it varies a little from many cauſes; firſt, according to the different heat of the atmoſphere, which expands water, and other fluids, infinitely more than it does ſolid bodies; and by that unequal diminution of the weight, makes it impoſſible to aſſign them a conſtant proportion, unleſs the heat be determined with the greateſt exactneſs. Secondly, according to the ſeveral degrees of purity in the water, which difference is ſometimes found not inconſiderable. Thirdly, according to the different purity of the *Metals*; for there is hardly any *Metal* found ſo very pure, but that it may be eaſily demonſtrated to be mixed with ſome others. Fourthly, according to the different weight of the atmoſphere itſelf; though the effects of its variations be not ſo conſiderable as of the reſt. *Cramer*, Art. Aſſay. p. 4.

Hence it is that there are, in a manner, as many different accounts of the ſpecific gravities of *Metals* as there are authors who have given an account of their experiments on the ſubject. However, except the *Metals* be of a very great impurity, the ſum of all the variations reſulting from all theſe cauſes, is not ſufficient to hinder any *Metal* from being certainly diſtinguiſhed from any other *Metal*, by its ſpecific gravity.

Slight variations in hydroſtatical experiments are indeed neither new things, nor are they by any means avoidable, either

either in making these or other experiments of affinity to them. By way of proof to such as may distrust this, from their never having made such experiments themselves, two very eminent testimonies may be produced. That most industrious and diligent mathematician Mersennus candidly acknowledges, that when he has occasion to mention the experiments of the learned Ghetaldus, and of the accurate French engineer Monsieur Petit, with his own, there will be often a variety of weight of some few grains; but he says, it is only like the variety of astronomical observations, which do almost always differ also by a few minutes or seconds; and to this he afterwards adds, that he expected not an exact uniformity between the observations of Ghetaldus, &c. already made, and the trials of any new experimenter, who would go through the work again. And our famous experimenter the lord Verulam confesses, that it is not to be doubted but that many of the bodies which he has set down in the table he has given, of their dimensions and weights, differ in the same species or denomination, some being heavier than others, and that therefore there is some contingency in the affair; so that tis not necessary that the individuals he made his trials upon should be exact standards of the weight of their respective species, or should, which makes directly to our present purpose, agree altogether to a tittle with the experiments of other men. *Boyle*, Hydrost. Experim. in Pref.

But this scarce evitable imperfection of hydrostatical experiments does not hinder, but that by their help we may make good estimates of the weights and bulks of very many bodies; and these estimates will be found not only preferable to those that can be made of the same bodies by geometrical instruments, but accurate enough to be very useful on a great number and variety of occasions.

METALS *for Specula*. In the making reflecting telescopes, the greatest article of all is the hitting upon a proper *Metal* for the specula. The common search is for a white and hard *Metal*, that shall be bright and durable; but Sir Isaac Newton advises, that at the same time great care must be taken that the *Metal* be not full of holes or pores, which, though so small as to be only discoverable by the microscope, yet will greatly impede the office of the speculum. This *Metal* may seem to take a very fine polish, but, in reality, the edges of these small pores will wear away faster in the polishing, than any other part of the *Metal*, and then however polite the *Metal* may seem, yet it will not reflect with such an accurate regularity as it ought to do. Thus tin-glass, mixed with the common bell-*Metal*, renders it more white and capable of reflecting a greater quantity of light than it otherwise would do; but then the fumes of this semi-*Metal* raised in the fusion like so many aërial bubbles, fill the *Metal* with microscopic pores. White arsenic both blanches the *Metal*, and renders it rather more dense than before, giving it no microscopical pores, unless the fusion has been too violent. The stellate regulus of Mars is recommended by the same gentleman to farther trials.

When the proper mixture is hit upon for the making such a *Metal*, there requires yet great caution in the polishing it. Whatever this is done with ought to be of the most extreme fineness, for if otherwise, its particles will scratch the face of the *Metal*, and make such microscopical holes as the tin-glass gives in the other instance. The proportion of arsenic is to be judged by trials, but something between a sixth and an eighth part of the weight of the copper seems to be the just proportion; when there is much less than an eighth, the *Metal* wants of its whiteness and brightness; and when much more, it is rendered too brittle. The method of making the mixture is this: The copper is first to be melted alone, and then the arsenic is to be put in; but while this mixture is stirred, great care must be taken to avoid the poisonous fumes. When the copper and arsenic are mixed, the tin is to be put in; this soon melts, and then the whole is to be stirred together, and poured off. Some add silver; but it is found, on trial, that this does as much harm in rendering the *Metal* soft, as it does good in rendering it white and luminous. Six ounces of copper, two ounces of tin, and one ounce of arsenic, seems one of the best proportions. It is to be carefully managed in the fire, and not kept too long in fusion, lest it grow porous by that means. Phil. Transf. N°. 81.

Colours from METALS. As metals have a strong texture in their metalline form, so they preserve their natural colours durably, unless corroded or dissolved by particular menstruums, after which their solutions strike particular durable colours, or afford the strongest stains.

Iron dissolved in stale small beer gives the beautiful yellow used in callico printing; when sublimed with sal armoniac it also affords a yellow: And the common iron-moulds made by ink are owing to the iron dissolved in the copperas of which ink is made.

Copper melted with zink appears of a gold colour; dissolved in aqua fortis, it affords a beautiful green; and in any alkali, a beautiful blue. And these solutions may be reduced to dry colours by crystallization or evaporation; and the same *Metal*, precipitated out of aqua fortis with common salts, gives the turquoise colour to white glass.

Tin, a white or colourless *Metal*, affords a light blue colour, when fluxed with antimony and nitre. The same *Metal* is necessary in striking the scarlet dye, with aqua fortis and cochineal; and its calx, by strong infusion, turns to a glass of an opal colour.

Lead, corroded by the fumes of vinegar, gives the fine white cerus; burnt in a strong naked fire, it becomes the strong red lead or minium; and melted into a glass with sand, is of the hyacinth colour. *Shaw's* Lectures, p. 171.

Silver being dissolved in aqua fortis, if chalk be put to the solution, turns of a beautiful purple or amethyst colour; and its own solution, though pale as water, durably stains the nails, skin, or hair, brown or black.

Quicksilver mixed with brimstone makes a black mass, and this, by sublimation, affords the beautiful red pigment, called cinnabar, or vermillion; and the solution of quicksilver being precipitated with common salt, yields a snow-white powder, which also turns black by being mixed with sulphur.

Gold, dissolved in aqua regia, affords a fine yellow liquor, which stains animal substances beautifully purple; and if the solution be sufficiently weakened with water, and mixed with a solution of tin, a fine red or purple powder may be procured, very useful for staining of glass and pastes to a beautiful red.

Fluxes of METALS. See the article FLUXES.

Granulation of METALS. See the article GRANULATION.

Medicines from METALS. All medicines that have lead in their composition, are scarce to be trusted for internal use; for we have numerous instances of the poisonous nature of this *Metal*, in the workers at the white lead or cerus-houses, and indeed in all who work on that *Metal*: And it were enough to banish the internal use of *saccharum saturni*, and the *tinctura antiphthisica*, to read in the *Miscellanea Curiosa*, Decad. 3. Obs. 30. how many men were poisoned at a time by drinking of prick'd wine, which had been rendered sweet by litharge.

Metals, however, do not act in the body unless dissolved; whence large quantities of crude mercury being swallowed, prove harmless for want of a proper menstruum to dissolve it in the stomach: But when crude mercury is dissolved in its proper menstruum, as in the making corrosive sublimate, we see it becomes one of the strongest poisons. Lead, Iron, and copper, being much more easily dissolved than quicksilver, are seldom taken without some remarkable effect, which must always prove the greater, the more of an acid humour, or in case of copper, even an alkaline is lodged in the stomach or intestines. The internal use of the crystals of silver, though sometimes successfully given in dropsical cases, should hardly be trusted, on account of their corrosive acrimony, which has sometimes occasioned bloody stools, and extreme weakness. The common tinctures of copper and solutions of blue vitriol, can scarce be taken internally with safety; as being not only emetic, but in some degree corrosive and poisonous. Even the *aurum fulminans* cannot be safely given till thoroughly washed from its salts; and even then if it meet with an acid solvent in the stomach, it may do very great mischief. Iron and tin have not been found so pernicious in the body, but rather beneficial, especially iron, when properly prepared and used.

Metallic bodies corroded by acids, generally erode when applied to sores. Some of these, sublimate mercury, for instance, and particularly arsenic, have shaken the whole frame of the body, when applied externally; and mercurial preparations do sometimes enter the blood, and produce a salivation. Med. Ess. Edinb. vol. 5. art. 24.

Salts of METALS. The salts of the several *Metals* have been medicines long known in the world, and are of excellent use in the cure of many diseases: But they might be of yet infinitely more service to the world, if a happier way of extracting them could be found than the general one now in use, of doing it by acids, and such strong and corrosive menstruums. Beside the mischiefs these menstruums bring as corrosives, which is assuredly much less than is vulgarly supposed, because they lose the greater part of this in acting on the *Metal*, they produce a great number of bad effects, and render the salts unfit for a great number of uses, by making them all vitriols, that is, by converting them into salts, which, like the common native vitriols, have a septic and violently acrimonious quality. The crystals, or salt of silver, called by the chemists, lunar vitriol, are a plain instance of this.

Borrichius and Kunkell devised another method to be used for obtaining the salts of *Metals*. This was the use of fire instead of acids, as the menstruum that should prey upon the *Metal*, and seeking the salts of all *Metals* from the mere action of a reverberatory furnace; but this method, though a very laudable attempt, yet is by no means calculated to be of general use, because the quantity of salts thus obtained is very small, and that obtained with great pains and expence. Kunkell has given the world an account of the effects of another method of treating *Metals*, of which he relates wonders; but

but he conceals the method. The ſolemn manner in which he declares the fact, however, ſeems to imply, that what he relates is truth; and he every where ſpeaks from his own perſonal knowledge, and the work of his own hands. The menſtruum he uſed was known by himſelf and many others, at Hall in Saxony, under the name of *Eſſentia Dulcis*; he ſacredly affirms, that this was neither acid nor corroſive, even in the ſlighteſt degree; that it left behind it no fæces, no ſaline nor earthy matter on evaporation alone; and that it more approached to the nature of ſpirit of wine, than to any other known liquid. He ſays, that this liquor diſſolved even gold, and that ſo perfectly, that it would all riſe with the liquor in diſtillation. Mercury being diſſolved in it, and the ſolution diſtilled in a retort, he ſays, that only a ſmall quantity of earthy matter remained in the retort, which was white, of a ſpongy texture, and fixed in the fire; and that the reſt of the body of the quickſilver was converted into a thin colourleſs and pellucid ſpirit in the receiver: And that gold, treated in the ſame manner, and diſtilled with a very gentle heat, was left at the bottom of the retort in form of a reſin; and that this reſin was ſoluble in common rectified ſpirit of wine, as was alſo the earth of the mercury; and that ſome days after the ſolution of this laſt earth, the ſalt with which this ſubſtance abounded, would ſeparate itſelf from the menſtruum, and form regular cryſtals at the ſide of the glaſs. This, he ſays, is the true ſalt of mercury, containing all the virtues of that *Metal*, and not converted into a vitriol or corroſive ſubſtance, by means of the menſtruum uſed to extract it.

When the ſalt has thus formed as many ſhoots as it will yield by this proceſs, the remaining liquor is to be evaporated gently, and there will be found a like ſalt at the bottom of the veſſel, of a white colour, an agreeable ſmell, and inſipid to the taſte: This, he ſays, is ſo fixed in the fire, that it is no more to be deſtroyed or altered by it, like the *Metal* from which it is obtained. It readily melts into a maſs in the fire; but if it be not immediately after that taken off from the fire, it will run through whatever veſſel it is melted in.

The author attributes to this ſalt all the wonderful virtues that the metal it is made from is known to poſſeſs; and gives inſtances of cures performed by it, which are ſo well atteſted, as ſcarce to leave any doubt of his veracity. He ſays, it works mildly by ſtool, urine, and ſweat. The caſes he gives of cures performed by it, are theſe: Two women, who were very bad with the venereal diſeaſe, two men in the laſt ſtages of hectic fevers, ſeveral perſons in bad kinds of the ſmall pox, and ſome in peripneumonies. The reſin-like ſubſtance into which gold is converted by the ſame operation, he ſays alſo may be transformed in the ſame manner into a white and ſubtile ſalt, of a very penetrating taſte; and to this he attributes great virtues in the cure of hæmorrhages and epileptic caſes, and adds, that it is an ingredient of the black compound powder, ſo famed for epileptic caſes, prepared at the public orphan hoſpital at Hall. *Kunkel*'s Diſſert. de Sal Met.

That a diſcovery of a manner of extracting the ſalts of *Metals* thus without the help of acids would be of great uſe to the world, is very evident, and the ſolemn manner in which this author aſſerts the having done it, ſeems to infer a probability of its being arrived at by others. He is very blameworthy in not declaring the method; but perhaps ſome hints may be gathered from what he has been pleaſed to declare about it.

Prince's METAL. See the article PRINCE.

METALLIC (*Cycl.*)—The antients have uſed this word very frequently as an epithet in the diſtinctions of the ſeveral ſubſtances which they have treated of. But it is to be obſerved, that the various writers have taken the word in a very different ſenſe. The medical writers in general mean by it ſomething of the mineral kind, that more or leſs partakes of the nature of ſome one of the metals, and that is wholly different from earths, ſtones, &c. In this ſenſe they call the *Lapis Armenus*, which indeed is properly not a ſtone, though we call it ſo, but an ore of copper, *metallic*; and by this term alone they diſtinguiſh it from the laps lazuli, which they call a ſtone. The naturaliſts, on the other hand, make no ſuch diſtinction, but call every thing *metallic* that is obtained out of the bowels of the earth; and thus ſtones, earths, ſalts, and even the liquid bitumens, are by them called *metallic* ſubſtances. The terms *metallic* oil, and *metallic* pitch, are found in the Greek naturaliſts, as the names of the *Petroleum* and *Piſſaſphaltum*; but the medical writers of the ſame time diſtinguiſh theſe by the name *Oryctæ*, which is properly foſſil, a word of a very wide ſenſe, taking in every thing produced in the earth; but the particular ones, which contained the particles of metals in a more or leſs perfect form, they ſeparated from theſe, and treated diſtinctly of under the name of the *Metallics*; chalk, ſand, earth, and ſtones of all kinds, are called by the Greek naturaliſts *metalla*, and the Latins have ſometimes uſed the word *metallum* for *lapis* a ſtone.

METALLIC *Germination*. See the article GERMINATION.

METALLIC *Vegetation*. See the article VEGETATION.

METALLORUM *Mater*. See the article MATER *Metallorum*.

METAPEDIUM, in natural hiſtory, a name given by ſome authors to a kind of ſtone, called by others *metatarſum*, and ſuppoſed to imitate a human foot. It is only a luſus naturæ in the formation of a common pebble.

METAPTOSIS, a word uſed by many phyſical writers to expreſs a change of one diſtemper into another, whether it be by *diadoche* or *diadexis*, as it is called; when the change is for the better, and the morbid matter removes from a more noble to an ignoble part: Or by *metaſtaſis*, when the change is for the worſe, and the morbid matter removes from an ignoble to a more noble part.

METASTASIS, Μετάστασις, *Remotio*, in rhetoric, is uſed for the removing the blame from the perſon accuſed to another perſon, or laying it upon ſomething as a cauſe. Thus Adam's excuſing himſelf by blaming Eve, is an example of the former; and the laying the crime of drunkenneſs upon the wine, is an inſtance of the latter. *Voſſ.* Rhet. l. 1. p. 147.

METATARSUM, in natural hiſtory, a name given by authors to a ſort of ſtone, ſuppoſed to repreſent a human foot. See the article METAPEDIUM.

METATARSIUS, a fleſhy maſs lying under the ſole of the foot, fixed by one end in the fore-part of the great tuberoſity of the os calcis, and running forward from thence, terminates in a kind of ſhort tendon, which is fixed in the tuberoſity, and poſterior part of the lower ſide of the fifth bone of the *Metatarſus*. It may move this bone, much after the ſame manner as the metacarpus moves the fourth bone of the metacarpus. *Winſlow*'s Anatomy, p. 226.

METATHESIS, a word uſed by medical writers for a change of place in ſuch humours, or other diſeaſed parts, as cannot be abſolutely removed or ſent off. Thus a *Metatheſis* of a cataract is a depreſſion thereof, ſo that it no longer ſhuts out the light.

METATOR, among the Romans, a quarter-maſter. Out of every legion a tribune, and ſome centurions, were appointed to go before the army, in order to chuſe a place for a camp, and aſſign and mark out quarters to each legion. *Pitiſc.* Lex. Antiq. in voc.

METAXA, a word uſed by ſome medical writers to expreſs ſilk.

METEGAVEL, in our old writers, a tribute or rent paid in victuals; which was a thing uſual in this kingdom, as well with the king's tenants as others, till the reign of king Henry the firſt. *Blount.*

The word is Saxon, *metegavel*; i. e. *cibi gablum, ſeu vectigal.*

METEL, in natural hiſtory, the name of a ſort of *nux vomica*, of the ſame ſhape with the common kind, but ſomewhat larger.

METEMPSYCHI, in church hiſtory, heretics, who, in imitation of the Pythagoreans, maintained the tranſmigration of ſouls. *Hofm.* Lex. in voc. See the article METEMPSYCHOSIS, *Cycl.*

METESSIB, an officer of the eaſtern nations, who has the care and overſeeing of all the public weights and meaſures, and ſees that things are made juſtly according to them. *Pocock*'s Egypt, p. 166.

METHOD (*Cycl.*)—The ſupreme law of the philoſophical *Method* is, to premiſe that which is neceſſary towards the underſtanding or eſtabliſhing what follows. *Wolf.* Diſc. Prælim. Logic. c. 4.

The mathematical and philoſophical *Method* are the ſame, as may be ſeen by the practice of the geometers of antiquity, who conſtantly obſerve the law here mentioned. Id. ib.

Several authors, as Ramus, Meſſrs. de Port Royal, &c. have accuſed Euclid of want of *Method.* Had theſe gentlemen attended to the ſupreme law of all true *Method*, they would have been more cautious in their cenſures. The jeſuit Caſtel has renewed this groundleſs accuſation; and to convince his reader how much he excels the antients, he begins his geometry by a *petitio principii.* Thus to prove that the oppoſite angles *a*, *b*, as alſo *c*, *d* are equal. He aſſumes this principle, that the two lines whoſe interſection forms theſe angles, are equally inclined to each other above and below. Now, being equally inclined to each other, is the ſame as forming equal angles, which is the very thing to be proved [a]. We find the ſame confuſion of thought, which he introduces by way of illuſtration, in bis doctrine of parallel lines; not to mention the abſurdity of *parallels being as it were one broad line* [b].—[[a] *Caſtel.* Math. Univerſ. p. 264. [b] Ib. p. 271.]

METHOD *of Maximis & Minimis.* See the article MAXIMUM, *Cycl.* and *Suppl.*

METHODISTS, in botany, perſons who have attempted that ſtudy upon certain principles, and have beſtowed their labours upn the diſpoſition and arrangement of plants, and allotting them proper and diſtinctive names. *Linnæi* Syſt. Nat. p. 1.

METOPIUM, in botany, a name given by Pliny to the plant which produces the gum ammoniacum. He ſays that the antient Greeks called it alſo by this name, but in that he errs. See the article AMMONIACUM.

METRENCHYTES, a name given by chirurgical writers to a ſort of ſyringe, contrived on purpoſe for injecting medicinal ſubſtances into the womb.

METRETES, the name of a meaſure uſed among the antients, containing ſomewhat more than nine gallons.

METROCELIDES, a word uſed by medical writers to expreſs a mark made by the imagination of the mother on the fœtus in utero.

METRONOMI, Μετρονόμοι, among the Athenians, officers that inſpected all ſorts of meaſures, except thoſe of corn; there were five of them in the city, and double that number in the *Pyræus*, in which the greateſt mart in Attica was kept. *Potter*, Archæol. l. 1. c. 15. T. 1. p. 83.

METROPTOSIS, a word uſed by ſome medical authors to expreſs a falling down of the womb, or prolapſus uteri. There is a plaſter calculated to be of ſervice againſt this caſe, and called hence, *emplaſtrum metroptoticum*.

METTESHEP, or METTENSCHEP, in our old writers, an acknowledgment paid in a certain meaſure of corn; or a fine or penalty impoſed on tenants, for their defaults in not doing their cuſtomary ſervices of cutting the lords corn. Paroch. Antiq. 495.

METUPORANGA, in zoology, the name of a Braſilian bird, called alſo by ſome *Tepetototl*, and by Aldrovand by the too general name *Gallus Indicus*.

It much approaches to the Gallinaceous fowls, called *Mitu* and *Pauxi*, of the ſame country, but differs from them in having no tail, if the deſcriptions of authors are accurate, and from the *mitu* in having a protuberance of the ſize of a cherry over the top of its beak. *Marggrave*'s Hiſt. Braſil. *Aldrov.* de Avib.

METYS, a word uſed by many of the antient writers to expreſs a ſubſtance collected by bees, in order to the ſtopping up cracks and crevices in their hives.

The old authors mention three kinds of ſubſtances uſed by the bees on this occaſion, the *Metys*, *Piſſoceros*, and *Propolis*. The moderns uſe only the latter term to expreſs every thing of this kind. The *Metys* and *Piſſoceros* ſeeming to have been only the ſame *Propolis*, more or leſs mixed with wax. This ſubſtance is a reſin, of a middle conſiſtence between the hard and the fluid ones. It is uſually of a reddiſh brown on the ſurface, and yellow within, and is collected from ſeveral trees, of which the poplar ſeems to be the principal, and the willow the next. *Reaumur*'s Hiſt. Inſ. vol. 10. p. 83. See the article PROPOLIS.

MEVIUM, a name mentioned by *Fallopius* and others, as given by ſome medical writers to the venereal diſeaſe.

MEUM, in botany, the name of a genus of umbelliferous plants, the characters of which are theſe: The flower is of the roſaceous kind, conſiſting of ſeveral petals, arranged in a circular form, and ſtanding on a cup which afterwards becomes a fruit, compoſed of two oblong ſeeds, which are gibboſe and ſtriated on one ſide, and flat and plain on the other. To this it may be added, that the leaves are finely divided, and ſtand on branched ſtalks. There is only one known ſpecies of this genus. The plants uſually called by this name, and different from the common *Meum*, being all ſpecies of fennel; and Mr. Tournefort obſerves, that this anſwers ſo well to all the characters of fennel, that he ſhould have made it no more than a ſpecies of that genus, but in compliment to its having been ſo long received under a ſeparate name. *Tourn.* Inſt. p. 312.

The root of *Meum* is eſteemed by ſome a very great medicine in malignant diſeaſes.

It is alſo eſteemed an attenuant, and is preſcribed wherever there are thick humours to be evacuated. It is given in aſthma's, and all obſtructions of the lungs, and is by many recommended in flatulencies, colics, and ſuppreſſions of urine, and of the menſes. Dioſcorides and Galen tell us, that the too frequent uſe of this medicine, or the taking it in too large doſes, will occaſion violent pains in the head. It may be given in ſubſtance from half a dram to two ſcruples, or from a dram to two drams in infuſion. *Geoffroy*, Mat. Med. vol. 2. p. 105.

It ought to be choſen as long and large as can be had, round, not flatted, plump, and full, and of an aromatic ſmell, and a ſomewhat acrid taſte, and ſuch as is not duſty or worm-eaten. It is ſudorific and diuretic; but the principal uſe now made of it is only as an ingredient in the Venice treacle.

MEUTANG, in botany, the name of a flower much eſteemed by the Chineſe, which, on that account, they call the king of flowers. It is larger than our roſe, and imitates its figure, only its leaves are more expanded. As its ſmell comes ſhort of that of the roſe, ſo in beauty the roſe is outdone by it. It has no prickles, and its colour is a mixture of white with purple, but ſo as to incline moſt to white; yet ſometimes there are found reddiſh and yellow ones. The tree it grows on is not unlike our alder tree, and is cultivated throughout that large empire with great care, being covered in the ſummer time with a ſhade to defend it from the ſcorching heat of the ſun. *Hofm.* Lex. in voc.

MEZEREUM, the female *ſpurge laurel*, in botany, a ſpecies of thymelæa. See the article THYMELÆA.

The bark of the root of this ſhrub, or the inner bark of the trunk, are preſcribed by ſome in dropſies, and other caſes where ſtrong purges are neceſſary; but it is ſo violent, that it ought never to be uſed internally. Externally it is uſed as a ſeaton, to draw a copious diſcharge from the ear in inflammations of the eyes.

MEZUZOTH, in the Jewiſh cuſtoms, certain pieces of parchment which the Jews fix to the door-poſts of their houſes, taking that literally which Moſes commands them [a], ſaying, “Thou ſhalt never forget the laws of thy God, but thou “ſhalt write them upon the poſts of thy houſe, and on thy “gates.” This expreſſion means nothing elſe, but that thou ſhalt always remember them, whether thou comeſt into thy houſe, or goeſt out. But the Hebrew doctors imagined, that the law-giver meant ſomething more than this. They pretended that, to avoid making themſelves ridiculous, by writing the commandments of God without their doors, or rather to avoid expoſing them to the profanation of the wicked, they ought at leaſt to write them on a parchment, and to encloſe it in ſomething. Therefore they wrote theſe words upon a ſquare piece of parchment, prepared on purpoſe, with a particular ink, and a ſquare kind of character, Deut. vi. 4, 5, 6, 7, 8, 9. “Hear O Iſrael, the Lord our “God is one Lord, &c.” Then they left a little ſpace, and afterwards went on, Deut. xi. 13. “And it ſhall come “to paſs, if thou ſhalt hearken diligently to my command-“ments, &c.” as far as, “Thou ſhalt write them upon “the door-poſts of thy houſe, &c.” After this they rolled up the parchment, and put it into a caſe of reeds, or other matter; they wrote on the end of the caſe the word *Shadai*, which is one of the names of God; they put it at the doors of their houſes, chambers, and all places moſt frequented; they fixed it to the knockers of the door, on the right ſide; and as often as they entered in, or went out, they touched it in this place with the end of their finger, which they afterwards kiſſed out of devotion. The Hebrew word *Mezuza* properly ſignifies the door-poſts of an houſe; but it is alſo given to this roll of parchment now mentioned. Leo of Modena may be here conſulted [b].—[[a] Deut. vi. 9. [b] Ceremon. of the Jews, part 1. c. 1. *Calmet*. Diction. Bibl.]

MEZZA *Pauſa*, in the Italian muſic, *half a pauſe*, intimates that the part wherein it is found muſt lie ſtill the time of a ſemi-breve in common time. See the article PAUSE.

MEZZA *Tirata*. See the article TIRATA.

MEZZO *Soprano*, in the Italian muſic, is the high tenor, which has the cleff C on the ſecond line.

MICA, in natural hiſtory, a name given by authors who have written of foſſils to many of the bractearia, or ſmall ſpangled talcs, whether in pure maſſes of themſelves, or immerſed in the matter of other foſſils.

The principal kinds of theſe are the white and the yellow, from their colour and ſplendid appearance, called the ſilver and gold glimmer, or *Mica aurea* and *Mica argentea*.

Of each of theſe there are ſeveral kinds, as many of the yellow and white bractearia, more or leſs, deſerve the name; but the moſt conſiderable ſpecies are thoſe called by Dr. Hill the *bractearium lucidum aureum bracteis parvis*, and the *bractearium argenteum lucidum bracteis variis*, the bright gold-colour'd bractearium with ſmall ſpangles, and the bright ſilvery bractearium with variouſly ſized ſpangles. Theſe have frequently led people of ſanguine imaginations, who have met with them in different places, to ſuppoſe they had found ores of gold and ſilver, but they, in reality, contain not the leaſt grain of either of thoſe metals, and are mere talc in ſmall flakes, accidentally colour'd. The yellow kind is found in many parts of the world, but no where ſo plentifully as in Arabia and Ægypt. In Germany and France there is alſo conſiderable plenty of it, and in our American plantations it is found in great abundance; nor is England without it even in various forms. We have ſome of it in pure homogene maſſes, ſome mixed among ſtony matter, ſome among ſand. The white is extremely plentiful in Sileſia and Bohemia, as alſo in France, Italy, and England. It is like the former, found either pure, or mixed among the matter of ſtone, and makes a very glittering and beautiful appearance. *Hill*'s Hiſt. of Foſſ. p. 77, ſeq.

MICARAGUÆ *Pomum*, a name given by ſome authors to the Spaniſh pear. *Chabræus*, p. 596.

MICHAH, a word uſed by ſome of the chemical writers to expreſs copper.

MICHALALATLI, in zoology, a name by which Nieremberg informs us, ſome of the Mexicans call the *achalalactli*. See the article ACHALALACTLI.

MICHELIA, in botany, the name of a genus of plants eſtabliſhed by Dr. Amman, the characters of which are theſe: The flower is monopetalous and of an anomalous kind, it is tubular, and opens into a kind of bilabiated mouth. The piſtil ariſes from the cup and finally becomes a fleſhy fruit, containing a kernel, or ſtone, divided into two cells, each of which contains one ſeed. This riſes to the ſize of a ſhrub, its branches are covered with a deep green bark, and do not grow ſtrait and even, but variouſly intorted; they ſend out many ſmall ſhoots, and are armed with very ſharp thorns of half an inch long; the leaves are about an inch and half long, and an inch broad; they ſtand on ſhort pedicles, and are of a pleaſant green on the upper ſide, and whitiſh underneath. The branches uſually terminate in long

and loose spikes of yellow flowers; these are each divided into four very uneven segments, the upper segment is very large and is arched; but the lower, and the side ones are much smaller and bend outwards. In the middle of the segments there stand two yellow stamina, sustaining each a round yellow head; the pistil arises between these, and is of the same colour, length, and thickness, with the stamina. The cup is very short, consisting only of one leaf; it is green and is divided in its upper part into two or three obtuse segments: The fruit is round and fleshy of the size of a walnut, green while young, but yellow when ripe, composed of a large quantity of a pale coloured pulp, surrounding a stone of an oval figure divided into two cells; in each of which is contained one kernel or seed. Act. Petropol. Vol. 8. p. 219.

MICROCOSMETER, a name given by Dolœus to an imaginary being, which he supposes to reside in the brain, and direct all the actions.

MICROCOUSTICS, the same with *microphones*. See the article MICROPHONES.

MICROPHONES, instruments contrived to magnify small sounds, as *microscopes* do small objects.

MICROSCOPE (*Cycl.*)—compound *Microscopes* sometimes exhibit a fallacious appearance, by representing convex objects, concave, and *vice versa*. See Philos. Transf. N°. 476. p. 387. See some accounts of the famous Leuwenhoek's *Microscopes* in the Philosophical Transactions, N°. 380. & 458.

The solar or *camera obscura Microscope*, and the *Microscope* for opaque objects, are the invention of Dr. Luberkhun; and have been executed by Mr. Cuff in England. Phil. Transf. N°. 458. p. 516, & 518.

Camera obscura MICROSCOPE. See *Solar* MICROSCOPE.

MICROSCOPE *for opaque objects*. The *Microscope* for opake objects remedies the inconvenience of having the dark side of an object next the eye: For by means of a concave speculum of silver, highly polished, in whose center a magnifying lens is placed, the object is so strongly illuminated, that it may be examined with ease. Phil. Transf. N°. 458. Sect. 9.

Solar MICROSCOPE. The *Solar Microscope* is composed of a tube, a looking-glass, a convex lens, and a *Microscope*. The tube is brass, near two inches in diameter, fixed in a circular collar of mahogany; which, turning round at pleasure, in a square frame, may be adjusted easily to a hole in the shutter of a window, in such a manner, that no light can pass into the room but through the aforesaid tube. Fastened to the frame by hinges, on the side that goes without the window, is a looking-glass, which, by means of a jointed brass wire coming through the frame, may be moved either vertically or horizontally, to throw the sun's rays through the brass tube into the darkened room. The end of the brass tube without the shutter has a convex lens, to collect the rays, and bring them to a focus; and on the end within the room, Wilson's pocket *Microscope* is screwed, with the object to be examined, applied to it in a slider. The sun's rays being directed by the looking-glass through the tube upon the object, the image or picture of the object is thrown distinctly and beautifully upon a screen of white paper; and may be magnified beyond the imagination of those who have not seen it. Phil. Transf. N°. 458. Sect. 9.

MICROSCOPIC *Objects*. All things too minute to be viewed distinctly by the naked eye, are proper objects for the *Microscope*. Mr. Hook has distinguished them to be exceeding small bodies, exceeding small pores, or exceeding small motions.

Exceeding small bodies must either be the parts of larger bodies, or things, the whole of which is exceedingly minute, such as small seeds, insects, sands, salts, &c.

Exceeding small pores are the interstices between the solid parts of bodies, as in stones, minerals, shells, &c. or the mouths of minute vessels in vegetables, or the pores in the skin, bones, and other parts of animals.

Exceeding small motions are the movements of the several parts or members of minute animals, or the motion of the fluids, contained either in animal or vegetable bodies. Under one or other of these three heads, almost every thing about us affords us matter of observation, and may conduce both to our amusement and instruction.

An examination of these objects, however, so as to discover truth, requires a great deal of attention, care, and patience, with some skill and dexterity, to be acquired chiefly by practice, in the preparing, managing, and applying them to the *Microscope*.

Whatever object offers itself as the subject of our examination, the size, contexture, and nature of it, are first to be considered, in order to apply it to such glasses, and in such a manner as may shew it best. The first step should always be to view the whole together, with such a magnifier as can take it in all at once, and after this the several parts of it may the more fitly be examined, whether remaining on the object or separated from it. The smaller the parts are which are to be examined, the more powerful should be the magnifiers employed; the transparency or opacity of the object must also be considered, and the glasses employed accordingly suited thereto, for a transparent object will bear a much greater magnifier than one which is opake, since the nearness that a glass must be placed at, unavoidably darkens an object if in its own nature opake, and renders it very difficult to be seen, unless by the help of the apparatus contrived for that purpose, which has a silver speculum. Most objects however become transparent by being divided into extremely thin parts. *Baker's* Microf. p. 52.

The nature of the object also, whether it be alive or dead, a solid, or a fluid, an animal, a vegetable, or a mineral substance, must likewise be considered, and all the circumstances of it attended to, that we may apply it in the most advantageous manner. If it be a living object, care must be taken not to squeeze or injure it, that we may see it in its natural state and full perfection. If it be a fluid, and that too thick, it must be diluted with water; and if too thin, we should let some of its watery parts evaporate. Some substances are fittest for observation when dry, others when moistened; some when fresh, and others after they have been kept some time.

Light is the next thing to be taken care of, for on this the truth of all our observations depends; and a very little observation will shew how very different objects appear in one degree of it to what they do in another; so that every new object should be viewed in all degrees of light, from the greatest glare of brightness to perfect obscurity, and that in all positions to each degree, till we hit upon the certain form and figure of it. In many objects it is very difficult to distinguish between a prominency and a depression, a black shadow and a black stain, and in colour between a bright reflection and whiteness. The eye of a fly in one kind of light appears like a lattice drilled full of holes, in the sun-shine like a solid substance covered with golden nails, in one position like a surface covered with pyramids, in another with cones, and in others with still different shapes.

The degree of light must always be suited to the object, if that be dark it must be seen in a full and strong light; but if transparent, the light should be proportionably weak; for which reason there is a contrivance both in the single and double *Microscope* to cut off abundance of the rays, when such transparent objects are to be examined by the largest magnifiers. The light of a candle for many objects, and especially for such as are very bright and transparent, and very minute, is preferable to day-light; for others a serene day-light is best; but sun shine is the worst light of all, for it is reflected from objects with so much glare, and exhibits such gaudy colours, that nothing can be determined from it with any certainty. This however, is not to be extended to the solar, or *camera obscura Microscope*; for in that nothing but sun-shine can do, and the brighter that is the better; but in that way we do not see the object itself on which the sunshine is cast, but only the image or shadow of it exhibited on a screen; and therefore no confusion can arise from the glaring reflection of the sun's rays from the object to the eye, which is the case in other *Microscopes*. But then in that solar way we must rest contented with viewing the true form and shape of an object, without expecting to find its natural colour; since no shadow can possibly wear the colour of the body it represents.

Most objects require also some management in order to bring them properly before the glasses. If they are flat and transparent and such as will not be injured by pressure, the best way is to enclose them in sliders between two Muscovy talcs or isinglasses. This way the feathers of butterflies, the scales of fishes, and the farinæ of flowers may be very conveniently preserved, as also the parts of insects, the whole bodies of minute ones, and a great number of other things. These are to be kept in sliders, each containing three, four, or more holes, and these must not be filled promiscuously; but all the things preserved in one slider should be such as require one and the same magnifying power to view them, that there may not be a necessity of changing the glasses for every object; and the sliders should be marked with the number of the magnifier it is proper to be viewed with. In placing the objects in the sliders, it is always proper to have a small magnifier, of about an inch focus, in your hand, to examine and adjust them by, before they are fixed down with the rings.

Small living objects, such as lice, fleas, bugs, mites, minute spiders, &c. may be placed between these talcs without injuring them, if care be taken to lay on the brass rings without pressing them down, and they will remain alive many weeks in this manner; but if they are too large to be treated thus, they should be either preserved between two concave glasses, or else viewed immediately, by holding them in the pliers, or sticking them on the point at the other end of that instrument.

If fluids come under examination, to discover the animalcules in them, a small drop is to be taken with a hair pencil, or on the nib of a clean pen, and placed on a plate of glass; and if they are too numerous to be thus seen distinctly, some water warmed by holding it in the mouth must be added to the drop, and they will then separate and be seen distinctly. This is particularly necessary in viewing the animalcules in the *semen masculinum* of all creatures; which, tho' extremely minute, are always so numerous, that without this caution their true form can seldom be seen. But if we are to see the salts in a fluid, the contrary method must be observed, and the

the plate of glafs muft be held gently over the fire, till part of the liquor is evaporated.

The diffection of minute animals, as lice, fleas, &c. requires patience and care; but it may be done very accurately by means of a needle and a fine lancet, placing the creature in a drop of water, for then the parts will readily unfold themfelves, and the ftomach, guts, &c. be very diftinctly feen.

Thefe feem the beft ways of preferving tranfparent objects; but the opake ones, fuch as feeds, woods, &c. require a very different treatment, and are beft preferved and viewed in the following manner.

Cut cards into fmall flips about half an inch long, and a tenth of an inch broad; wet thefe half-way of their length in gum-water, and with that faften on feveral parcels of the object, and as the fpots of cards are of different colours, fuch fhould be chofen for every object as are the moft different from its own colours. Thefe are very convenient for viewing by the *Microfcope* made for opake objects with the filvered fpeculum; but they are proper for any *Microfcope*, that can view opake bodies.

A fmall box fhould be contrived for thefe flips, with little fhallow holes for the reception of each; and this is conveniently done, by cutting pieces of pafte-board, fuch as the covers of books are made of, to the fize of the box, fo that they will juft go into it, and then cutting holes through them with a fmall chiffel, of the fhape of the flips of card, thefe pafte-boards having then a paper pafted over their bottom, are cells very proper for the reception of thefe flips, which may be taken out by means of a pair of plyers, and will be always ready for ufe.

Great caution is to be ufed in forming a judgment on what is feen by the *Microfcope*, if the objects are extended, or contracted, by force or drinefs.

Nothing can be determined about them, without making the proper allowances; and different lights and pofitions will often fhew the fame object as very different from itfelf. There is no advantage in any greater magnifier than fuch as is capable of fhewing the object in view diftinctly; and the lefs the glafs magnifies, the more pleafantly the object is always feen.

The colours of objects are very little to be depended on, as feen by the *Microfcope*; for their feveral component particles being by this means removed to great diftances from one another, may give reflexions very different from what they would, if feen by the naked eye.

The motions of living creatures alfo, or of the fluids contained in their bodies, are by no means to be haftily judged of, from what we fee by the *Microfcope*, without due confideration; for as the moving body, and the fpace wherein it moves, are magnified, the motion muft be fo too; and therefore that rapidity with which the blood feems to pafs through the veffels of fmall animals muft be judged of accordingly: Suppofe, for inftance, that a horfe and a moufe move their limbs exactly at the fame time, if the horfe runs a mile while the moufe runs fifty yards; tho' the number of fteps are the fame in both, the motion of the horfe muft notwithftanding be allowed the fwifteft; and the motion of a mite, as viewed by the naked eye, or through the *Microfcope*, is perhaps not lefs different. *Baker's* Microfcope, p. 62.

MICTUS *Cruentus*. See the article *Bloody* URINE.

MID-*Feather*, in the Englifh falt-works, the name given to a fort of partition placed in the middle of the furnace, over which the pan is fet for boiling the fea-water or brine into falt.

This partition divides the body of the furnace into two chambers. See the article SALT.

MID-*Ship Beam*. See the article BEAM, *Cycl.*

MIDA, in natural hiftory, the name of a worm or maggot, of which is produced the purple fly, found on bean-flowers, and thence called the bean-fly.

MIDAD *Albendi*, in the materia medica of the Arabians, a name given to the common indigo blue.

The exprefs meaning of the words is Indian ink; but this is an erroneous name, founded on Pliny's mifunderftanding the words of Diofcorides. The Greeks in general have called the common writing ink *Melan*; but they have alfo ufed this word *Melan* as an adjective, expreffive not only of black, but of deep blue. Thus Theophraftus has called both the violet flowers and the fine deep blue fapphires, *Melanes*. Pliny, finding him call the indigo when of a very fine and deep colour, *Melan Indicon*, thought it to be different from the common indigo, and thence fuppofed it a fort of Indian ink. Thus Indian ink has become a fort of name for this blue.

MIDDLING-*Teeth*, in the manege, are the four teeth of a horfe that come out at three years and a half, in the room of other four foal-teeth, feated between the nippers and the corner-teeth; from which fituation they derive the title of *Middling*. There's one of them above, and one below, on each fide of the jaws. See the article TEETH.

MIDYON, a word ufed by Theophraftus, as the name of a fpecies of oak. It is prefcribed by fome of the old phyficians, in their compofitions; but is ufually fuppofed to ftand there, by an error of the copies; the word meant being mify.

MIFRES, a name by which fome writers have called afphaltum. See the article ASPHALTA.

MIGRATING-*Bog*.—Thefe foft maffes of earth have been fometimes known to move out of their place. An inftance of this there was in Ireland, in the year 1697, about Charleville, in the county of Limerick. There was heard for fome time a noife under ground like that of thunder at a great diftance, or almoft fpent; and foon after this the earth of a large bog in the neighbourhood began to move, and a hill or rifing fituated in the middle of it ftood no longer above the level of the reft, but funk flat.

The *bog* not only moved itfelf, but moved with the neighbouring pafture-lands, tho' feparated by a large and deep ditch; the motion continued a confiderable time, and the furface of the moving earth rofe into a fort of waves, but without breaking up or burfting any where. The pafture-land rofe very high, and was carried on in the fame motion till it refted upon a neighbouring meadow, the whole furface of which it covered, remaining fixteen feet deep upon its furface. The whole quantity of the bog was torn from its former feat, and left great gaps in the earth where it had joined, which threw up foul water, and very ftinking vapours. Phil. Tranf. N° 233.

All the country came in to fee fo ftrange a fight as this, for it continued moving a long time; but few gueffed the true caufe of it, which was this: A more than ordinary wet fpring occafioned the rifing of the bog to a great height in one part, and thence propagated itfelf through the whole bog; fo that the hill in the midft was undermined, and naturally funk flat; this and the greater than ordinary weight of this large bog preffing upon the adjoining pafture-land, forced up its foundations, which were only a loofe fand. This was pufhed on fideways where there was a defcent from the bog, and at length having given the bog more room, all was quiet and remained in that ftate. The bog was more than forty acres of ground.

MIGRATING-*Birds*. See the article *Birds of* PASSAGE.

MIHA, in the materia medica, a name ufed by fome authors for ftyrax. *Ger.* Emac. Ind. 2.

MILAX, a name by which *fmilax* is often meant by the Greek writers. The adding or taking away the letter *s* from words beginning with an *m*, was a thing common and indifferent among them. This name is however one of the fynonimous terms of the Greeks, fometimes being ufed as the name of the yew-tree, and fometimes as that of the creeping plant we call *fmilax* at this time. Diofcorides, and Galen, and moft of the later Greek authors, call the tree *Milax*, and the herb fmilax, as if there were a difference between the two names; but this is not regularly kept up by any of them, and in the antients is not regarded at all; there being no more difference between the words *Smilax* and *Milax*, than between fmaragdus and maragdus, as that word, the name of the emerald, is at times varioufly written.

MILDEW (*Cycl.*)—Some have fuppofed the blight and *Mildew* to be both the fame thing, but very erroneoufly. The *Mildew*, properly fo called, fometimes refts upon the leaves of trees in form of a fatty juice, and fometimes on the ears of corn; it is tough and vifcous to the touch, and the fun's heat drying it up, it becomes yet more vifcous and hard, and fo daubs over the young grains in the ear, that they can never after expand themfelves properly, nor grow to their due fize or weight. Bearded wheat is lefs fubject to the *Mildew*, than the common fort; and it is obferved, that newly dung'd lands are more fubject to the *Mildew*, than others. The moft happy remedy for this is out of the farmer's power, but often happens naturally; this is a fmart fhower of rain, and immediately afterwards a brifk wind. This wholly difperfes it. If the *Mildew* is feen before the fun has any power, it has been recommended by many, to fend two men into the field with a long cord, each holding one end, and drawing this along through the ears, the dew will be diflodged from them before the fun's heat is able to dry it to that vifcous ftate in which it does the mifchief. Some alfo fay, that lands which have for many years been fubject to *Mildews*, have been cured of it by fowing foot with the corn, or immediately after it. See the article BLIGHT.

MILE (*Cycl.*)—In Scotland the *Mile* is equal to 1184 paces, every pace being five feet; fo that the Scotch *Mile* contains 5920 feet. Tr. Pract. Geom. p. 4. See the article MEASURE.

MILIARIUM, the name of a tall and narrow veffel, ufed in the bathing of the antients, for heating water to any degree, to give warmth to the reft. See Mem. Acad. Infcript. Vol. I. p. 127.

MILIARY *Fever*. See the article PURPUREA *Febris*.

MILIOLUM, a word ufed by fome medical writers, to exprefs a fmall tumor in the eye-lid, of the fize and fhape of a feed of the common millet.

MILITARY *Rewards*. See the article REWARDS.

MILIUM, *Millet*, in the Linnæan fyftem of botany, makes a diftinct genus of plants; the diftinguifhing characters of which are, that the calyx is a glume containing feveral flowers, and compofed of three valves, which are of an oval figure and pointed;

pointed; the two inner ones are placed opposite to one another; the third is situated behind one of these. The flower is smaller than the cup, and is made up of two valves which are of an oval figure, and one of them much smaller than the other. The stamina are three very short capillary filaments, the antheræ are oblong, the germen of the pistil is roundish, the styles are two in number and are very slender, the stigmata are like pencils. The flower incloses the seed, and does not open to let it fall out. The seed is single, and of a roundish figure. *Linnæi* Gen. Plant. p. 17. See Tab. 1. of Botany, Class 15.

Millet is reckoned by Pliny the most fertile of all grain; one grain of it producing three Roman sextaries. *Hoffm.* Lex. in voc. See the article SEXTARIUS, *Cycl.*

MILIUM *Arundinaceum*, in botany, a name by which some authors call the lacrymæ Jobi, or Job's tears. *Herm.* Cat. p. 426.

MILIUM *Indicum*, in botany, a name by which some authors call the maize, or Indian wheat. *Park.* Theatr. 1138.

MILK (*Cycl.*)— *Milk* is evidently one of the best nourishments of the body; and it is not wonderful that it should prove so, when we consider that in all cases of nourishment the proximate matter taken to nourish ought to be as like as may be to the body to be nourished by it. We subsist by the same things by which we are generated, and even while in the state of a fœtus in the womb, we are nourished not by blood, as some suppose, but by a lacteous juice, which is separated from the blood in the uterus by means of the placenta, as it is in the breasts of women who give suck, by glandules and tubuli destined for that purpose. Meats which we daily feed upon pass down into the stomach indeed in their own form, but they do not nourish us till they are changed into chyle, or a milky liquor.

Milk being analysed is found to be composed of fatty, serous, and terrestrial parts; and these its constituent principles being easily mixed and separated again, are made of it matter for the nourishment of the different parts of the body. The serous part, which is also nitrous, being a proper vehicle to convey through the vessels the fatty parts, which are as well adapted to all the offices of nutrition as any substance can be. It is easy to infer from this account of *Milk*, that it is not only a proper food for children, but for grown people also; but proper regulations are to be observed as to its use in particular cases; no aliment any more than this being capable of suiting all constitutions and circumstances. Meat in the stomach is converted into chyle, or a substance like *Milk*; this chyle passes into the heart through the blood-vessels, and its finest and most spirituous parts are there transmuted into the red part of the blood; and after this the other grosser parts of it are by different elaborations transformed into bile, and the several other humours in the body. It is evident that these humours, as well as the blood itself, must all have a supply; and that meat cannot give this supply, till it is converted into chyle or *Milk*; how much labour then is sav'd the animal functions by giving at once into the stomach chyle ready form'd, that is *Milk*; and in cases where the action or juices of that organ are so debilitated as not to be of power to convert the meat into chyle, what remains but that the person must die slowly, by a want of the supplies of the several fluids of the body, if something be not given that is capable of passing into the blood with less preparation than meats are; and what is so proper on such an occasion as *Milk*, which is already so nearly allied to the nature of the fluid that should have been there separated from meat, that it will readily supply all its offices.

MILK-*Diet* is useful in the gout and stone. See the article STONE.

Dr. Cheyne recommends *Milk* and seed-diet with water for drink, as the surest preservative against diseases, and cure of them. See the articles CANCER, PALSY, FITS, GOUT and STONE.

Upon opening a vein, especially after meals, *Milk* is sometimes found instead of blood. See Phil. Transf. N°. 6. pag. 100.

The salt of *Milk* may be prepared by boiling whey to one half, then filtrating it; the coction and filtration is to be continued, till the liquor becomes of the consistence of a syrup. This being put into a cellar to chrystallize, the salt will be formed into a cake of a saccharine taste, resembling manna. This preparation is Dr. Gaubius's, and is somewhat different from that which Valentini, in his *Medicina Nov. Antiq.* alledges to be the famous saccharum lactis, so much cried up by Lodovicus Festi, and recommended by others as an infallible cure for the gout. Med. Eff. Edinb.

MILK *of Sulphur*. See the article SULPHUR *Precipitatum*.

MILK, in the wine trade. The coopers know very well the use of skim'd *Milk*, which makes an innocent and efficacious forcing for the fining down of all white wines, arracks, and small spirits; but is by no means to be used to red wines, because it discharges their colour. Thus, if a few quarts of well-skim'd *Milk* be put to a hogshead of red wine, it will soon precipitate the greater part of the colour, and leave the whole nearly white; and this is of known use in the turning red wines when prick'd into white; in which a small degree of acidity is not so much perceived. *Shaw's* Lect. p. 209.

Milk is, from this quality, of discharging colour from wines, of use also to the wine-coopers, for the whitening of wines that have acquired a brown colour from the cask, or from having been hastily boiled before fermenting; for the addition of a little skim'd *Milk* in these cases, precipitates the brown colour, and leaves the wines almost limpid, or of what they call a water whitenefs, which is much coveted abroad in wines, as well as in brandies.

Womens MILK.— The *Milk* is often a very troublesome and dangerous thing to women in their lyings-in, and subjects them to many painful disorders. About the third or fourth day after delivery they are usually affected with chilnesses and shiverings, which are well known to be owing to that cause, and are therefore not to be treated as a disease, nor any medicines to be given in them; only it is proper to keep the person warm, and promote perspiration, especially in the breasts. Sometimes indeed this symptom is joined with a febrile heat, or a real inflammatory fever, which is then to be taken off by the proper means. See the article *Inflammatory* FEVER.

Very frequently there come on inflammations of the breasts, of the erysipelous kind; these are usually taken off by the external use of spirit of wine and camphor with a little saffron in it, and by carefully keeping the parts warm.

The *Milk* often proves very difficult to be drawn out; this is to be helped by the keeping the body carefully open by carminative and emollient clysters, by keeping up a gentle diaphoresis, and by attemperating medicines mixed with the milder alexipharmics. The breasts are all the time to be kept carefully covered with flannel, and gently pressed and rubbed at times; and finally they are to be drawn by means of a pipe, or by the mouth of an experienced person.

Deficiency of MILK, is also a very common complaint, and it is in some cases absolute, there being no *Milk* at all derived into the breasts; in others, it is only a partial one, there being some *Milk*, though not enough to supply the child with nourishment. A total deficiency of *Milk* most frequently happens to persons who have their first child when somewhat advanced in years, and to such as are of a choleric disposition; but a partial deficiency of it is often owing to a saltness of the serum, and sometimes to the want of nourishments, and often is brought on by sorrow.

When saline and bilious humours are in fault, then lac lunæ, calcin'd crystal, and other absorbent powders, become of great use: Some also prescribe the powder of earth-worms carefully dried, and the voiding the humours by stool, by means of gentle purges: When a want of nourishment is the only occasion of it, the *Milk* may always be recovered in a proper quantity by means of good foods, with *Milk* and other nourishing fluids.

An over-abundance of MILK is as common a complaint, as a deficiency of it, and requires as much care in the treatment, otherwise the person is frequently subject to nodes and abscesses in the breast. The proper remedies are the eating and drinking more sparingly, and the letting two children suck instead of one.

Many people do not suckle their children, and therefore find it necessary to drive away their *Milk* absolutely. This is best done by taking internally the digestive salts, with diaphoretic and diuretic medicines. Externally, it is proper to apply to the breasts bags of the dried leaves of parsley, mint, chervile, &c. with the seeds of coriander and parsley, and a little camphor; and spirit of wine with camphor, and a little saffron is to be rubbed in, or linnen rags wetted in it and applied. Cerates may also be made of white wax melted in oil of almonds, with a little camphor, and applied to the breasts fresh every morning and evening, or oftner if necessary.

A too great thinness of the MILK, is another common complaint with nurses; this is to be laid sometimes to the diet, sometimes to the concoction, and sometimes to the unnatural tenuity of the humors; in this case the *Milk* is often perfectly watery, and the child is thrown into an atrophy by it. The remedies for this are, a change of diet, and a purging of the primæ viæ by some gentle cathartic, and afterwards a strengthening of them by bitters, and stomachic medicines. Sometimes also, it is necessary to evacuate the serous humours by the common phlegmagogues, such as jalap in proper doses mixed with a little powder'd ginger, which is an excellent corrective for it.

The *Milk* is sometimes salt to the taste, and sometimes of a bilious yellow colour; and these distemperatures of it usually throw the child into colics, diarrhœa's, vomitings, cutaneous eruptions, with scabs, and sometimes absolute ulcerations, and sometimes into fevers. In this case, the nurse or parent is to take the absorbents and nitrous medicines, with intermediate purges; thus, powders of crabs-eyes, oyster-shells, and purified nitre, with small doses of rhubarb between whiles, often perfect a cure; but during the course of taking these remedies, and for some time afterwards, the diet must be under some regulations, particularly salt foods are to be avoided; and all acids, aromatics, and strong liquors, either wholly let alone, or taken very sparingly. The person must also carefully avoid all violent passions of the mind, as anger, fear,

fear, and the like; and from all violent emotions of the body.

A contrary extreme to the thinness and watery appearance of the *Milk* before described, is, *a mucous thickness of it.* This is principally troublesome and dangerous to the parent, as it is apt to bring on tumors and nodes in the breast. The method of treatment in this case, is to give gentle alexipharmics for some days, then the gentle laxative medicines in small doses, and finally to allow a moderate use of wine.

Stagnations of the MILK. These are very frequent in lyings-in, and are to be discussed by the same method as was before ordered for the sending it back, in cases where persons do not choose to give suck; and, to the things there directed, may be added, the internal use of sperma-ceti and of calcin'd mountain crystals, in powder; and externally, cataplasms of sperma-ceti with some volatile urinous salt, and the gentle compression of the breasts by wearing strait cloths about that part.

Nodes of the Breasts often arise from the abundance and the mucous nature of the *Milk.* They are to be discussed by plasters of sperma-ceti, with annise, parsley, and coriander seeds; and by gently rubbing with a soft flesh-brush, as also by wearing some animal's skin that has a thick fur on it, which at once serves the double office of warmth and a gentle friction.

Abscesses of the Breasts very often happen also from the same causes; and these when there appears no hopes of discussing them are always to be brought to suppuration as quick as possible. A maturating plaster is to be laid on the parts that are to be broke, and the other parts are to be rubbed with spirit of wine and camphor, and saffron infused in it. When the matter in the abscess is ripe, if the skin do not burst of itself it is to be immediately opened with a lancet; after this a plaster of equal parts of diachylon simplex and that with the gums, with a little comphor mixed in it is to be applied; and afterwards digestives are to be wholly avoided, and no dressings but balsamics allowed. The liquor of myrrh, or a mixture of essence of myrrh and amber and spirit of turpentine, make an admirable dressing; and internally, gentle purges are to be given, and the milder dieuretics, with the nitrous and saline medicines.

Cracks and fissures of the Nipples, is another terribly troublesome complaint with those who give suck. The best applications to these, are the oil of eggs with the liquamen of the buds of the poplar, oil of wax, linseed oil shook together with the whites and yelks of eggs, a liniment made of marygold-flowers and fresh butter, an ointment of liquorice, and the liquor produced from the flowers of mullein and marrygolds, heated together in an oven. The sucking out the *Milk,* by means of a glass pipe, is very necessary during the continuance of this complaint; but the best method of preventing it, is the applying white wax to the nipples for some time before, as well as after the time of the labour.

The Smallness of the Nipples is a trouble to many nurses; these when the complaint is only owing to their lying-in, the breasts are to be forced out by the sucking of a robust child of six or more months old, by the application of the common glass-pipe first made warm, and by the sucking of a grown person experienced in such cases: All natural accidents of this kind may be cured by this means; but often the nipples have been so forced in by stays, at the very time of their growth in young girls, and this force continued so long, that no art is able to recal them to their natural state, or make them fit for an infant to suck from.

The mischiefs that sometimes attend persons who have given suck, in the weaning of children, or on the death of a child, and the *Milk* being left undrawn out, are to be avoided, by letting some other child suck a little at a time, and that less and less every day, and by drawing afterwards a little every day with a pipe.

It is very common among nurses to be extremely scrupulous about diet, and to require the nicest foods for the creating good *Milk*; but it is evident, that though some care is necessary to this purpose, yet it is not this; for the poorer people, who live on the coarsest food, often have the richest *Milk.* The whole necessary caution seems to consist in avoiding excess, and feeding as much as possible on simple foods, without too many vegetables, and not to lead too sedentary a life.

Things hard of digestion are to be abstained from, as also acids; too salt meats, and all flatulent things, and the acrid and aromatic things, are to be very carefully meddled with; since, tho' they do not affect the mother, they seldom fail to bring distempers upon the child. There is no better drink for those who give suck than malt liquors, when they are well settled and clear. Stronger things, even wine in those who are habituated to it, tho' it do not hurt them, is to be refrained from, since it subjects the child to convulsions and many other disorders.

Over large draughts of cold liquors, and the exposing the breasts too much to the cold, are often the causes of very great disorders both in the mother and the child. Gentle exercise, and motion of the body in general, is highly serviceable to nurses, as is also that of the breasts in particular. The gently shaking and pressing them throwing off the aqueous part of the *Milk,* and filling the lactiferous ducts more freely and copiously, than would otherwise be done. The improper methods of dress in some places, and squeezing the girls into slenderness by strait stays, often occasions the lactiferous ducts to be so contracted, and the nipples so repressed, that no art can afterwards bring the person to be properly qualified for suckling a child. *Junker's* Consp. Med. p. 732, seq.

Violent passions of the mind are extremely injurious to those who give suck. It is very common to see nodes and abscesses of the breasts brought on by these alone, and erysipelatous inflammations are as frequent in persons of other habits, from the same causes. The child also is often thrown into diarrhœa's, by it; and in general, it is a very necessary rule to squeeze and shake the breasts to discharge the *Milk* after a great fright, or a violent fit of passion, before the child is suffered to suck. If the menses appear at the time of giving suck, the child is usually greatly injured by the alteration the *Milk* suffers.

When women are newly lain in, if the breasts become turgid, and there is danger of the *Milk's* coagulating in them, the child if it be strong should be immediately put to suck; but if otherwise, the breasts are to be gently shaken and pressed to discharge the redundance, or another child, or grown person, put to suck them.

Extract of MILK, a sweet dry extract of cows milk made by evaporation.

Fred. Hoffman recommends this extract boiled with pure water to the quantity of what is exhaled of the *Milk,* as an excellent drink in many disorders, where *Milk* itself is not proper. See his Dissert. *de saluberrima seri lact. virtut.* oper. Tom. VI. p. 13.

Milk is often thought improper with purgatives, and it certainly does render some persons costive; but this does not hold generally, nor perhaps for a long time, even in those whom it may so affect at first. Hoffman recommends an ounce of manna dissolved in a pint of *Milk* as a good laxative.

Moon's MILK. See the article LAC *Lunæ.*

MILK-WORT. See the article LACTARIA.

MILK-*wort,* in botany. See the article GLAUX.

MILL (*Cycl.*)—MILL-*Dams.* A very firm way of making these in a quick or running sand, which is usually found a very troublesome circumstance in the making them, is by laying the foundation with unslacked lime; which, by slacking among the sand, runs together into a hard stone, which gives a very firm and sure foundation. *Plot's* Staffordshire, p. 336.

MILL-*Stones.* The *Mill-stones* which we find preserved from antient times, are all small and very different from those in use at present. Thoresby mentions two or three such found in England, among other Roman antiquities, which were but twenty inches broad; and there is great reason to believe that the Romans, as well as the Egyptians of old, and the antient Jews, did not employ horses, or wind, or water, as we do, to turn their *Mills,* but made their slaves and captives of war do this laborious work; they were in this service placed behind these *Mill-stones,* and pushed them on with all their force. Sampson, when a prisoner to the Philistines, was treated no better, but was condemned to the *Mill-stone* in his prison. The runner or loose *Mill-stone* in this sort of grinding, was usually very heavy for its size, being as thick as broad. This is the *Mill-stone* which it is expresly prohibited in Scripture to take in pledge, as lying loose it was more easily removed. The Talmudists have a story, that the Chaldæans made the young men of the captivity carry *Mill-stones* with them to Babylon, where there seems to have been a scarcity at that time; and hence, probably, their paraphrase renders the text "have borne the *Mills,* or *Mill-stones*;" which might thus be true, in a literal sense. They have also a proverbial expression of a man with a *Mill-stone* about his neck; which they use to express, a man under the severest weight of affliction. This also plainly refers to these small sort of stones.

MILLAINS, according to Mr. Wingate, are the third subdivision of the primes in Gunter's line; and express the thousandth parts of such primes.

MILLEFOLIUM, *Yarrow,* in botany, the name of a genus of plants, the characters of which are these: The flower is of the radiated kind; its disk is composed of flosculès, and its outer edge of semi-flosculès, which all stand up on the embryo-seeds, and are contained in one general squammose cup, of a sort of cylindric figure. The embryo's finally ripen into slender seeds; to this it is to be added, that the leaves are always finely divided, and the flowers are collected into tufts.

The species of *Yarrow,* enumerated by Mr. Tournefort, are these: 1. The great white-flowered *Yarrow,* called Achillæa. 2. The common white-flowered *Yarrow.* 3. The great purple-flowered *Yarrow.* 4. The common *Yarrow,* with purple flowers. 5. The noble *Yarrow,* or scented *Yarrow.* 6. The Montpelier sweet *Yarrow.* 7. The hoary alpine *Yarrow,* with flesh-coloured flowers. 8. The hoary alpine *Yarrow,* with beautiful flowers. 9. The woolly yellow *Yarrow.* *Tourn.* Inst. p. 495.

The

The common *Yarrow* which is in flower on our ditch-banks, and in dry paſtures the greateſt part of the ſummer, is a much nobler medicine than is ſuppoſed. The medical writers have ſaid much of it as a vulnerary, and recommended its external uſe in tumors and ulcers; and internally, as a remedy for hæmorrhages of all kinds; in which caſes experience ſhews us, that a ſtrong decoction of the whole plant, roots and leaves, does wonders. The flowers of this plant have the ſingular property of yielding a fine deep blue oil, by diſtillation. The flowers of Chamæmile do the ſame; but we do not know any other plant, except theſe two, that do it.

MILLEMORBIA, in botany, a name given by ſome authors to the ſcrophularia, or figwort, from its ſuppoſed virtues in many diſeaſes. *Ger.* Emac. Ind. 2.

MILLEPEDA, in conchyliology, the name given by authors to a ſpecies of murex of the ſpider ſhell-kind, ſo called from the great number of prominences in the ſhape of points called feet in this ſeries of ſhells, which ariſe from its lip which is greatly extended. The body of the ſhell is full of bumps and tubercles, and the tail is long and crooked. See the article MUREX.

MILLEPEDES (*Cycl.*)—Well-known inſects, uſed on many occaſions in medicine. This inſect is otherwiſe called *Aſellus*, or *Oniſcus*, in Engliſh the *Wood-louſe*. Mr. Ray deſcribes ſeven different ſpecies of this inſect, ſome of which we ſee every day, others are more rare. Theſe are, 1. The common *Millepes*, called the *Aſellus Aſininus*; this is thinner and flatter than the blue kind, and carries antennæ ſtrait forward, and its colour is a pale browniſh grey; the laſt ring of its body is acute, not annular, and the appendages of the ſides are forked, as is alſo the tail. This kind is common in old walls, and under the barks of old trees. 2. The greater blue or livid *Millepes*; this is conſiderably larger than the former, and is of a duſky bluiſh black colour; the laſt ring of its body is annular, not pointed, its tail is not forked; its body, like that of the former, is divided into fourteen rings, and it eaſily rolls itſelf up into a round ball. 3. The great ſea *Aſellus*; this is three times as large as the common kind, its body is divided into twelve rings, its eyes are large and round, the antennæ are long, and are compoſed only of three points, the tail is double, and has four horns; its colour is ſomewhat paler than the common kind. 4. The mountain *Aſellus*; this is of the ſize of the livid kind, and in the ſame manner rolls itſelf up when touched; its body is divided into eleven rings, and its colour is a mixture of black and red. 5. The great Cornwall *Aſellus*; this is about an inch in length, its antennæ are very long, it has fourteen feet, and is of a reddiſh brown colour; it is diſtinguiſhed from all the other kinds by the ſhape of its tail, which is a flat lamina, divided into three points at the end; the eyes are ſmall and black, and the body is compoſed only of ſeven rings beſide the head and tail; the feet have all a ſort of hooks at their end, and the hinder legs are longer than any of the others. 6. The *Aſellus aquaticus*, or water *Millepes*; this is ſomewhat ſmaller and ſlenderer than the common kind, its antennæ are very ſlender, and its colour is a pale browniſh grey, with a dark ſtreak running down the back; its body conſiſts of ſeven joints, each of which has a pair of legs; its hinder pair of legs are longer than the others, and it has another peculiar mark, which is, there are two very ſlender horns iſſuing from the tail, and making a kind of fork. The 7th kind is the ſhort ſea *Millepes*; this is broader as well as ſhorter than the common kind, and has two appendages on each ſide the tail, which it uſes in ſwimming; this is of the ſame colour with the common kind, but has a black liſt running down the back; the eyes are ſmall, the body conſiſts of ten joints, beſides the broad tail; it rolls itſelf up in the manner of the blue *Wood-louſe*, and has under each ring of the body, beſide a pair of legs, two fins that ſerve it in ſwimming. *Ray's* Hiſt. Inſ. p. 41.

The firſt and ſecond kinds are uſed in common in medicine; but the ſecond or blue kind, which rolls itſelf up into a ball, is the proper medicinal kind.

Beſide theſe proper *Aſelli*, there are ſome other ſpecies commonly called *Pulices marini*, which ſeem greatly to approach to their nature. Theſe are, 1. The horned ſea *pulex*; its body is compoſed of twelve joints, it has ſeven pair of legs, and the hinder ones are longer than the others, the antennæ are a pair of very large horns, and at the baſe of theſe there ſtand two other very ſhort and ſlender ones: It has fins to ſwim with, and it is of a whitiſh colour, and very ſlender body. 2. The *pulex marinus* of Bellonius; this is of the ſhape of the common *aſelli*, but ſomewhat ſlenderer and rounder bodied, and its legs are much longer; its back is brown, its eyes are large and black, and the antennæ are articulated and have two ſmall ones growing from their roots; its body is pellucid, and it moves very ſwiftly in the water; the tail is compoſed of a large bundle of hairs. This is found in great plenty under ſtones by the ſides of rivers near the ſea. 3. The freſh-water *pulex*; this differs very little from the laſt ſpecies, but is ſingular in the places it inhabits, which are the banks and mud of hot ſprings, in which no other animal can live. *Ray's* Hiſt. Inſect. p. 44.

MILLEPORA, in botany, a name by which Linnæus diſtinguiſhes that genus of ſea-plants, of a hard ſtructure and full of holes, which are not ſtellate or radiated, in which it differs from the madrepora.

MILLERS-*Thumb*, in ichthyology, an Engliſh name for the fiſh called alſo the bull-head, and by authors the cottus. See the article BULL-HEAD.

Some are ſo erroneous as to ſuppoſe this fiſh, and the loach to be the ſame. See the articles LOACH, and COBITIS.

MILLIARIA *Cohors*, in antiquity. See the article COHORS *Equitata*.

MILLMOTH, in natural hiſtory, the name of an inſect approaching to the nature of the beetle, but having no ſheath wings. It is common in the abodes of millers and bakers, and other perſons who deal in meal.

MILPHOSIS, a word uſed by the antient medical writers, as a name of the diſeaſe of the eye-lids, by which the hairs fall off from them, and the edges become red and tumid.

MILTOS, in the natural hiſtory of the antients, the name of what we call reddle, a red earth of the ochreous kind, uſed in painting. The Greeks uſed the word in a leſs determinate ſenſe, and called all the red earths by this name, with adjectives derived from the names of the places where they were found, &c. to denote their differences.

Many however have thought too boldly, that the cinnabar found native, and called by the Greeks *minium*, was alſo comprehended under this name; but for this there is no warrant, and the paſſage in Pliny which gave birth to the opinion, is merely an error in the copies from the falſe pointing; and all that Pliny ſeems really to have meant, was, that the Greeks called reddle by the name of *Miltos*, and minium by that of cinnabar. Reddle ſeems to have been of very antient uſe in painting; for we have plain teſtimony in Homer, that it was uſed by the Greeks in the time of the Trojan war, that poet calling their ſhips by an epithet which ſignifies their being painted with reddle; and the accounts of the earlieſt painters, which tell us that they uſed only four colours, make reddle to be one of theſe four. *Hill's* Theophraſt. p. 124. See the articles REDDLE and RUBRICA.

MILVAGO, in ichthyology, a name given by Geſner and ſome others, to a fiſh called by authors in general *milvus* and *cuculus*, and by ſome *lucerna*, and the flying fiſh. It is a ſpecies of the trigla, and is called by Artedi the trigla, with a ſnout bifid at the extremity, and the ſide-lines forked near the tail. See the article TRIGLA.

MILUS, μιλος, a name given by the Greek writers to a plant uſed in garlands, and ſometimes to a tree. Theophraſtus evidently uſes it as the name of a tree, and Crato as that of a garland herb.

It ſhould ſeem by compariſon of what they ſay of this *Milus*, that it is no other than a corruption of the word *milax*, or *ſmilax*. This we know was uſed as the name of the yew-tree, and alſo as the name of that climbing plant which we at this time call ſmilax; and what ſtrengthens the opinion is, that this creeping ſmilax was one of the common herbs uſed in garlands, having got into eſteem on theſe occaſions by the length and toughneſs of its branches, which were eaſily twiſted into any form, and wound round about whatever they pleaſed.

Pliny tells us, that it was a melancholy herb, and not fit for garlands; becauſe it had been once a virgin, and was turned into this form in conſequence of an unhappy love for the inconſtant youth crocus; but if this were to have been an objection to the uſe of theſe plants among the antients, thoſe garlands muſt have been either very thin, or made of paltry weeds; for the fancy of their poets had ſcarce let any flower or herb worthy obſervation paſs without ſome ſuch hiſtory.

There ſeems to have been no plant uſed ſo frequently in the rites of Bacchus as the *ſmilax*, or this climbing herb; and this is by the earlieſt writers ſometimes called *Milax*, or *Milos*, and ſometimes *Smilax*; ſo that it ſhould ſeem that they were only the ſame word differently ſpelt.

Euripides frequently mentions it in his Bacchi, and ſometimes celebrates it in flower, ſometimes in fruit, calling it καλλικαρπος, and ανθεσφορος, the elegant fruited and the flowery ſmilax; and this laſt ſenſe of it Pliny has taken, calling it *anthophorus*, the flowery ſmilax. Athenæus, in his fifth book, mentions the bacchides as carrying ſpears covered with vines, ivy, and ſmilax, or *Milos*. In this ſenſe of ornamenting garlands, ſpears, &c. they meant only the herb ſmilax, not the yew-tree.

MILVUS, the *flying fiſh*, the name of a fiſh remarkable for the length and ſize of its gill-fins, which it ſometimes makes uſe of to fly with: It is of the cuculus or gurnard kind, and is called by ſome the rondine, and by others the falcone. See Tab. of fiſhes, N°. 41.

Its general ſize is about ſix inches in length; its head is broad and flatted, and its body long and rounded, and very ſlender toward the tail. The ſpace of the forehead between the eyes is large and hollow, and the whole head is covered with a ſtrong bony cruſt; this is rough and of ſeveral colours, as blue, yellow, and purple: This cruſt covers alſo ſome part of the back, and terminates in two very long and ſtrong ſpines, which lie down upon the back: It is covered with very hard ſcales, every one of which riſes into a ſharp tubercle in the middle. The back is of the ſame colours with the head, but ſomewhat

fomewhat dufkier. Its eyes are large, and the coverings of the gills terminate on each fide in a very long and fharp thorn, which is ferrated on the outfide. The mouth is fmall, and is placed low in the head; and its jaws are granulated, rather than toothed. Its belly is white, and its tail forked. Its gill-fins, commonly called its wings, are fo long as when laid clofe to the body to reach to the tail, and they are as it were double, a fmall fin compofed of a feries of fhort nerves or rays connected by a fmall membrane ftanding before each. Thefe wings are of an olive colour on their upper fide, and are fpotted with very beautiful blue fpots near their edges. *Willughby*'s Hift. Pifc. p. 284.

This fifh, when it pleafes, is able to rife out of the water and fly to a confiderable diftance in the air; but when its wings are dry, is obliged to plunge again into the water to moiften them. It does this often, when purfued by an enemy; and whole fhoals have been feen thus flying together. It is common in the Mediterranean, and fome other feas; but is not known in ours, nor in any of the colder climates.

MILVUS, in ornithology, the name of the common kite: A bird diftinguifhed from all other birds of prey, by its forked tail. It remains with us the whole year; but in many other countries is a bird of paffage. *Ray*'s Ornithol. p. 41.

MILVUS *Æruginofus*, in zoology, the name of the moor-buzzard; a bird of the long-wing'd hawk kind, fmaller than the common buzzard, and not fo flat on the head. Its beak is large and crooked, covered with a greenifh yellow fkin near the top, and black in other places. Its mouth is bluifh within. Its head is of a whitifh orange colour, variegated with black ftreaks; its throat is of the fame colour; and all the reft of its body, as well back as belly, is of a dufky ruft colour, only that in each wing there is a yellowifh white fpot; and the feathers at the root of the tail are yellowifh. Its legs are long and flender, and of a yellowifh colour. The infide of its wing-feathers are whitifh. It is common with us about heaths and marfhes. *Ray*'s Ornithol. p. 42.

MIMOSA, the *fenfitive plant*, in botany, the name of a genus of plants, the characters of which are thefe: The flowers are ufually collected into tufts or heads, and each confift of one leaf of a fennel-like fhape, containing a great number of ftamina: The piftil arifes from the bottom of the flower, and finally becomes either a fimple bivalve pod containing a number of oblong feeds, or elfe a compound one made up of feveral parts joined to one another by a fort of tranfverfe articulation, each containing one roundifh feed. To this it is to be added, that the leaves of all this genus of plants, when touched, become capable of a fort of reciprocal motion. *Tourn.* Hift. p. 605.

The fpecies of *Mimofa*, enumerated by Mr. Tournefort, are thefe: 1. The common *fenfitive fhrub*. 2. The prickly and more *fenfitive Mimofa*. 3. The broad-leav'd *fenfitive plant*, with pods collected in round clufters. 4. The Jamaica *fenfitive plant*. 5. The prickly Pernambuco *Mimofa*. See the article SENSITIVE *Plant*.

MINA, or MNA, among the antient Greeks, a piece of money worth an hundred drachmas.

The *Mina* was fomewhat more than three pounds Sterling; fixty *Minæ* made the Attic talent. *Danet.* in voc. See the article COIN, *Cycl.*

MINCA, a name given by the antients to a very coarfe and bad kind of myrrh.

MINCHA, in the Jewifh cuftoms, offerings of meal, cakes, or bifcuits, made in the temple of the Lord [a]. The Seventy have fometimes preferved this word in their tranflation [b]; but inftead of *Mincha* they read *Manaa*, which doubtlefs was the received pronunciation in their time. We find *Manaa* in the fame fenfe, in Baruch i. 10 [c].—[[a] Levit. ii. 3, &c. [b] See the Greek of Jerem. xvii. 26. Dan. ii. 46. 2 Kings viii. 5, 9. xvii. 7. xx. 12. 2 Chron. vii. 7. Nehem. xiii. 5, 9, &c. [c] *Calmet*. Dict. Bibl.]

MINE (*Cycl.*)—The difcovery of *Mines* is not always attended with a certainty of advantage. The firft thing to be confidered in regard to it, is whether it can be dug to profit; and to be able to determine in this refpect, we are duly to weigh the nature and fituation of the place, and compare the refult of the whole with the profit from the richnefs of the ore, and the charges of digging, fmelting, and working it.

A *Mine* is either found in a mountain, a hill, a valley, or a flat; of thefe, mountains and hills are dug with greateft eafe and conveniency, chiefly becaufe the drains and burrows, that is, the adits and avenues may be here readily cut both to drain off the water, and to form gangways for bringing out the ore. In whatever place the *Mine* lies we are to look for the veins, which rains or other accidents may have difcovered; and where fuch a vein is found, if it be tolerably large and rich, it is beft to open the *Mine* there. Otherwife the moft commodious place for fituation is to be chofen, that is, neither on a flat, nor on the tops of mountains, but in their fides. *Shaw*'s Lectures, p. 244.

The beft fituation for a *Mine*, is a mountainous, woody, wholefome fpot, of a fafe eafy afcent, and bordering upon a navigable river. For wood is indifpenfably neceffary for making the engines and inftruments, building the huts, fencing in the works, and working the ores. But tho' wood fhould be wanting, if a navigable river be nigh, that may be fupplied, as water-carriage is cheap. Water however muft never be wanting. This is beft fupplied by a large river, and is neceffary on a thoufand occafions, to wafh the ores, turn the works, &c. Good convenience of carriage muft alfo be regarded, both for the carrying the ore or metal to market, and the bringing neceffaries to the workmen: For provifions are feldom to be found where there are *Mines*. See the articles DIGGING, MINING, and TRACING.

MINE-*Dial*, is a box and needle with a brafs-ring divided into 360 degrees, with feveral dials graduated thereon; generally thus made for the ufe of *Miners*.

MINERAL (*Cycl.*)—*Englifh*-MINERALS. Dr. Woodward has obferv'd, that the Englifh *Minerals* are much more valuable and numerous, than has been generally fuppofed. Fullers-earth, a thing fo cheap as to be difregarded by many, he obferves, is of almoft as much value to our commerce, as any article of foreign production. The property this earth has of imbibing oil and greafe, is not confined to the trifling fervice of taking out accidental ftains in clothes, but it is of fo much ufe in cleanfing the wool and the cloth made of it, that we could never have flourifhed in the cloth-trade in the manner we have done, had we not this foffil among us fo very plentiful and cheap, and at the fame time fo excellently good. This earth is one inftance of the pre-eminence of our foil above others. Another inftance we have in our black-lead or wadd, a *Mineral* of great ufe and value in feveral branches of trade and arts; and which is found no where fine and good, except in England, and in our colonies; and that of the laft place, tho' better than the black-lead of other nations, is greatly inferior to our own.

The amber and jet of England are found in confiderable quantity, and are equal to thofe of any other part of the world. Our cannal-coal comes very near the beauty of jet; and even our common coal for firing is greatly fuperior in goodnefs, to that of any other part of the world, and is no where found in fuch vaft plenty as with us. The Englifh earths and gravel are well known to be fuperior to thofe of other countries, in none of which fuch grafs-plats or fuch gravel-walks are to be feen, as in the Englifh gardens. We have ftones, flates, flags, and the other neceffary foffils for building, in fufficient plenty.

Vitriol and alum are found in greater plenty in England, than in any other country; and are fo eafily worked or procured from their ores, that we can fell them cheaper than any other people. *Woodw.* Cat. Fof. Vol. I. p. 5.

Tin is another article in which England has always had a great pre-eminence; the county of Cornwall alone produces more tin than all the world befide; and the tin of England is well known to excel that of other nations, as well in value as in quantity.

Lead ore is alfo richer in England than in any other country, and is found in greater quantity here than any where elfe; befide this, it runs more kindly in the fire, and requires lefs trouble and expence in the working, than any other lead; and is, when wrought, much finer and more ductile, than any other lead.

This does not arife from any peculiarity in the metal, for lead is the fame in all countries, when equally purified; but the fpar which lies about, and is mixed with our lead-ore, is of fuch a nature and difpofition, that it is eafily wrought upon and readily parts from it, leaving the metal more pure than it can be procured by the common large operations in other countries; fo that they are forced to fend it away much lefs pure than ours is.

Copper and iron are alfo found in England in very great plenty, and feveral ores of thefe metals have of late been brought into ufe, which were not known before the modern improvements in chemiftry.

MINERAL *Waters*. See the article *Mineral* WATERS.

Earth of MINERAL *Waters*. See the article EARTH.

MINERAL *Juices*. See the article JUICE.

MINERAL *Courts*, *Curiæ Minerales*, in law, courts for regulating the concerns of lead-mines; as *ftannary courts* are for tin. *Blount*.

MINERVALIA, among the Romans, called alfo *Quinquatria*, were feafts celebrated in honour of Minerva. They began March 19th, and lafted five days. The firft day was fpent in prayers to the goddefs; the reft in offering facrifice, feeing gladiators fight, acting tragedies upon mount Albanus, and reciting pieces of wit, wherein the conqueror had a prize given him. Scholars had then a vacation, and made a prefent to their mafters, which was called *Minerval*.

MINICULATOR, among the Romans, a fervant who embellifhed any writing with *Minium*. *Hoffm*. Lex. in voc. See the article MINIUM, *Cycl.* and *Suppl.*

MINING, the finking or digging into the earth in fearch of metals, or other valuable foffils.

The neceffity of cleaving and opening rocks has been always accounted one of the moft troublefome articles in the bufinefs of *Mining*; as being often compofed of fuch ftone as tools can work but very flowly upon in the common ways. Fire and gunpowder have been the two things principally had recourfe to on thefe occafions; and both fuccefsfully, but in dif-

ferent ways. The fire calcines ftones, and they then eafily become fhattered to pieces, and give way to tools that would not touch them before; but in this cafe, befide the expence of wood, the hindrance of the labourers is an article to be confidered, for the rocks are made fo hot all about the place where the fire has been, that the people cannot get to work again of a day or two, and then the effect of fire reaches but a little way in the rock.

Gunpowder makes its way much farther, and at the fame time is much cheaper and does not delay the work, but the labourers may go on immediately afterwards. There have been many ways contrived of ufing this, but one of the fimpleft and beft, feems that delivered by Mr. Beaumont, in the Philofophical Tranfactions. For this there are only three fimple inftruments required, a borier, a gun, and the quinet or wedge. Thefe are the names the *Miners* on Mendip hills give the inftruments. The borier is an iron inftrument, fteeled at the end; it is two foot two inches long, and is fomewhat thicker at the fteel'd end than in any other part: The ufe of this is to make the hole in the rock deep enough to receive the powder. The gun is about fix inches long, and an inch and quarter in diameter; and has a hole drilled through it, to receive the priming. The quinet is a wedge of iron of about fix inches long, and fo fhaped that its flat part on one fide joins with a flat part in the gun made to receive it, and by that means the gun is faftned very firmly in its place. Philofoph. Tranf. N°. 167. p. 854.

The manner of ufing thefe inftruments, is this: One man holds the borier on the rock, turning it round while another forces its point in by blows of a large hammer on the other end. When the hole is made fomewhat deeper than the length of the gun, they dry it with a rag, and then put into it two or three ounces of powder; over this they lay a paper, and then they put the gun into the hole, and faften it in by driving in the quinet or wedge againft its flat part. When the powder and gun are thus fixed, they pafs down a wire through the hole drilled in the gun, and with this they pierce a hole through the paper which covers the powder; they then prime the gun, and lay a train with a lighted match; but all go out of the *Mine* before the gunpowder takes fire, and as foon as it has gone off they go down to work again, finding the rock fplit and the inftruments unhurt. The paper in this cafe is put over the powder only that the tools may be fafely employed in driving down the gun and the quinet, becaufe were not the powder covered it might do mifchief to the workmen by going off by fome fpark caufed by ftriking either againft thofe inftruments or againft the rock itfelf.

MINIUM, (*Cycl.*) in the natural hiftory of the antients, a name given to what we now call *Cinnabar*. A native mineral of a fhinining red colour, out of which quickfilver was extracted.

This native mineral becoming much in ufe, was foon adulterated, and that commonly with lead ore calcined to a rednefs; and hence, after the two words *Minium* and *Cinnabar* had been long ufed in common, the cinnabar became retained only to the native mineral, and the *Minium* to that adulterated with lead-ore, or to the red adulterating matter alone, which is the fenfe in which it is ftill ufed.

The word *Cinnabar* however, by which they at laft diftinguifhed it, among the oldeft writers on medicine, was ufed as the name of a very different fubftance, a vegetable juice of a ftrong red colour, called by us dragon's blood, and among them long believed to be the dry'd blood of dragons; and when the antients called the mineral body here defcribed by the fame name, they always diftinguifhed the other cinnabar, where they had occafion to name it, according to their ufual method by an adjective derived from the name of the place whence it was brought, calling it *cinnabari Indicum*, the Indian cinnabar.

The native *cinnabar* of the antients was the fame with ours at this time, and was found in the fame variety of forms. Theophraftus tells us, that it was hard and ftony, and that they had it from Spain and Colchis, where it was produced among the rocks. *Hill's* Theophraft. p. 140.

Many have fuppofed, from the name of a factitious *cinnabar* among the moft antient writers, that they were acquainted with our method of making the artificial *cinnabar*; but this was by no means the cafe. What they called factitious *cinnabar*, was, according to the fame Theophraftus, no other than a fine arenaceous fubftance of a fcarlet colour, and very bright and fhining, which they had from one particular place only, which was in the country above Ephefus. This they carefully collected, and rubbed to a fine powder, in veffels made of ftone, and afterwards wafhed it in other veffels of brafs or of wood; the coarfer matter they went to work upon again, rubbing and wafhing it as before, till by thefe repeated powderings and wafhings they feparated all the pure cinnabar, which always funk to the bottom of the veffels, leaving the accidental foulneffes at top.

The factitious *cinnabar* of the antients, was therefore no other than a preparation of a native mineral, which contained a quantity of true cinnabar mixed among a large quantity of other matter, and the operation confifted in nothing but the feparating it from its other matter. The invention of this is attributed to one Callias, an Athenian, who belonged to the filver mines; and was difcovered, as moft other things have been, by accident. This man had got together a vaft quantity of this fand, fuppofing from its colour and brightnefs that it contained gold; and tho' he found himfelf miftaken in that, yet the working on it in hopes of difcovering that precious metal difcovered to him this excellent paint. See the article CINNABAR, *Cycl.* & *Suppl.*

The method in which *Minium* is made in large quantities with us, is this: They firft burn lead in a furnace into a kind of litharge, by continually ftirring it while melted with an iron rake; this they afterwards grind with two pair of ftones, which deliver it from one to another, the firft pair grinding it coarfer, the fecond finer; thefe are worked by means of a mill which moves fix pair of them at once. When thus reduced to a fine powder, it is wafhed and then put into a furnace, and is burnt with a reverberatory fire for two or three days, all the while they continue ftirring it with a large iron rake, hung on a fwivel or iron hook; and toward the end of the time they watch its being of the right colour. When this is doing, the fire muft not be carried beyond a certain degree, left the matter clod and run together. *Ray's* Englifh Words, p. 138.

MINIUM, in medicine, is ufed externally; it obtunds the acrimony of the humors, allays inflammations, and is excellent in the cleanfing and healing of old ulcers: It is ufed, on thefe occafions, in many of the plafters and ointments of the fhops.

MINORATIO, a word ufed by the antients to exprefs a flight or moderate evacuation, only ferving to leffen the humors, not to carry them off.

MINOW, or MINIM, in ichthyology, a name given by the Englifh to the fmall fifh, called by authors the phoxinus. According to the new Artedian fyftem, this is a fpecies of the cyprinus. See the articles CYPRINUS, and PHOXINUS.

MINT (*Cycl.*)—All the forts of *Mint* of which we have feveral propagated in gardens for medicinal ufe, are to be propagated by parting the roots in fpring, or planting cuttings in any of the fummer months, but they muft have a moift foil; and if the weather proves dry, they will require very frequent waterings, after they are firft planted. They fhould be planted in beds of four foot width, with walks two foot wide between them, and fhould be fet at five inches diftance. And they fpread fo faft at the roots that the beds fhould never ftand above three years before they are taken up and tranfplanted; for the roots after this time will mat and clog together, fo as to choak one another. *Miller's* Gardener's Dict. See the article MENTHA.

Many people are fond of *Mint* fallad early in the fpring; the way to propagate this, is to take up fome roots of *Mint* before Chriftmas, and plant them pretty clofe upon a moderate hot bed, covering them an inch deep with frefh earth; the beds muft then be covered either with mats, or frames and glaffes, and in a month's time the *Mint* will come up and will foon be fit for ufe.

When *Mint* is cut for drying, it fhould be done juft when it is in flower, and muft always be done in a dry day; for if cut in wet weather, the leaves will change black. It fhould then be ty'd in fmall bunches, and hung in a fhady place upon lines.

If the foil be good, *Mint* will afford three crops every fpring; but after July, they feldom are fo good, fo that the fhoots made after that time fhould be fuffered to remain till the end of September, to be cut for drying. After this cutting there fhould be about an inch of frefh earth fifted over them, which will make them fhoot much better the following fpring.

No plant grows fo vigoroufly and readily in water as *Mint*; and therefore none is fo proper to try experiments in vegetation upon.

It is generally fuppofed, that plants are the fame in their tafte and virtues in whatever foil they grow; and this is true in regard to all of them, while they live and flourifh; the greateft difference being only in degree.

But plants removed into a foil in which they cannot thrive, but in which they will be killed in time, are often altered in their nature, before they perifh. This is inftanced in nothing fo clearly as in experiments made on *Mint*, growing in glaffes of water. Let feveral fhoots of the plant grow in this manner till very vigorous and ftrong, and then place near one of them a glafs of water in which fea-falt is diffolved, remove one of the roots from the frefh water into this, and the plant will be killed in a few days; and its leaves, ftalk, and every part will tafte ftrongly of fea-falt, though none could be imbibed any other way than by this fingle root. Let another plant of *Mint* be fet near a bottle of ink, and one of its roots put into the ink, the whole plant will in a few days become black, and after that yellow, and will tafte of the copperas.

It is lefs wonderful that thefe unnatural falts fhould affect the *Mint* in this manner, than that the infufion of another plant fhould do it; yet this is evidently the cafe. Let a quantity of the feeds of wild garlic be bruifed and put into water, and let two or three of the roots of a vigorous plant of *Mint* growing in common water be put into this liquor, the whole plant will in a few days decay, and the whole plant being chew'd

chew'd in the mouth will be found to have a very ftrong flavour of garlic.

MINT, in medicine, is a famous ftomachic and carminative; it is alfo efteemed a great cephalic. There is a fimple water, and an effential oil of it kept in the fhops. The plant itfelf is taken by way of infufion or decoction, and enters many compofitions for the above intentions.

MINUET, or MENUET, in mufic, a compofition anfwering to a kind of dance of the fame name, faid to be invented in Poitou; the motion whereof is triple. It has commonly two ftrains, each played twice over; the firft has four or eight bars; the laft note of which fhould be either the *dominant*, or *mediant* of the mode, never the final; and the fecond has eight bars, it ufually ends on the final of the mode, with a pointed minim or whole bar. *Broffard.*

MINUTE *Tithes*, *Minores Decimæ*, fmall tithes of wool, lambs, pigs, butter, cheefe, &c. 2 Inft. 649. *Blount.*

MIRALETUS, in ichthyology, a name given by Bellonius and fome other writers, to the fpecies of ray, commonly called by others *raja oculata*. This is accurately diftinguifhed by Artedi, by the name of the ray with a fmooth back and belly, and with a row of fpines round the eyes, and three other rows of them on the tail.

MIRROR (*Cycl.*)—*Burning*-MIRRORS. An experiment has of late been tried with a machine invented by Mr. De Buffon at Paris, conftructed of a number of *Mirrors*, which feems the great fecret of Archimedes revived, and vindicates the credit of antiquity in this point.

The machine confifts of 140 fmall plane *Mirrors*, each about four inches long, and three broad; thefe are fixed at about a quarter of an inch diftance from each other upon a large wooden frame about fix foot fquare, ftrengthened with many crofs-bars of wood; for the mounting of thefe *Mirrors* each of them has three moveable fkrews, which the operator commands from behind, and which are fo contrived that the *Mirror* can be inclined to any angle, and in any direction that meets the fun; and by this means the folar image of each *Mirror* is made to coincide with all the reft.

They firft tried the experiment with only 24 of the *Mirrors*, which readily fet on fire a combuftible matter which they had prepared of pitch and tow daubed upon a deal-board, at the diftance of fixty-fix French feet. The only difficulty that was found, was the making the folar images exactly coincide; but this was the fault of the apparatus. Philof. Tranf. N°. 483.

This trial, and fo much fuccefs from it, engaged the inventor to pufh the attempt much farther; he put together therefore a kind of polyhaedron confifting of 168 pieces of plane looking-glafs of fix inches fquare each, and by means of this with the faint ray of the fun in the month of March he fet on fire fome boards of beech-wood at an hundred and fifty foot diftance; and by increafing the number of the *Mirrors*, he is in hopes of doing the fame at nine hundred feet off. This machine has, befide other advantages, the convenience of being able to burn downwards or horizontally, as one pleafes; and it burns either in its diftant focus, or in any nearer interval, which our common burning-glaffes cannot do, their focus being wholly fixed and determined. And perhaps this machine may afford a manner of meafuring either light or the different degrees of heat of burning bodies. The difficulty is to find the method of marking the degrees and of fixing a point of comparifon, for the point of kindling will not determine it, becaufe that chiefly depends upon the greater or lefs degree of inflammability of different combuftible bodies. Phil. Tranf. N°. 483.

MIROUETTE, in the manege, is ufed for a dapple bay. See the article DAPPLE.

MISADIR, or MIXADIR, a name given by fome authors to fal armoniac.

MISEN, MISSON, or MIZEN, in a fhip, denotes either the maft, or fail of that name; but at fea, they always mean the fail when the word *Mifen* is ufed.

The ufe of the *Mifen* is, to keep the fhip clofe to a wind: Wherefore if a fhip is apt to gripe too much, they ufe no *Mifen*. But it is often ufed when a fhip rides at anchor, to back her a-ftern; fo that fhe may not foul her anchor, on the turning of the tide; and fometimes a fhip lies a-try with her *Mifen* only. See the article MAST, *Cycl.*

Set the MISEN, at fea, the word of command to fit the *Mifen*-fail right as it fhould ftand.

MISEN-*Stay*, in a fhip. See the article STAY, *Cycl.*

MISEN-*Yard*, in a fhip. See the article YARD, *Cycl.*

MISERERE-*Mei*, (*Cycl.*) a name by which many authors call the *Iliaca Paffio*, or what is vulgarly termed a twifting of the guts. Medical writers diftinguifh this into three kinds: 1. The convolutionary. 2. The herniofe. And 3dly, the obftructionary.

In the convolutionary kind, the fituation of the inteftines in regard to one another is altered, and very frequently has a remarkable duplicature. In the herniofe kind, the inteftines, diftended with fæces and with flatulencies, are received into the fcrotum, or fome other part, fo as not eafily to be reduced into their natural places. And in the obftructionary, there is no other caufe but a violent coftivenefs.

The *Miferere* differs from the ordinary kinds of colic, in degree, as all the fymptoms are greatly more violent in this cafe; and in its fituation, as the ilion and fmall guts are affected in this, and in the other colics ufually the larger; and it is always a much more dangerous cafe than an ordinary colic.

Signs of it. Thefe are extremely fharp and violent pains acrofs the navel, a remarkable anxiety of mind, with frequent eructations and heartburn, and great internal heat; a violent obftruction in the bowels, in which glyfters have very little or no effect; and as the difeafe increafes, a vomiting, which, as it continues, at length brings up the ftools by the mouth, with violent pains, and frequent faintings; after this, unlefs the medicines take place, there comes on an inflammation of the ilion, and thence a fuppuration and mortification, on which the pains inftantly go off, and the patient falls into cold fweats, and dies in a very little time after. It is a very rare cafe, and though many colics are called by this name, yet in reality it is rarely met with. People, however, of all ages and fexes, are equally fubject to it from the following caufes.

Caufes of it. Thefe are either a convolution of the inteftines, with an immediate inflammation, or a tumour in the parts of the inteftine contained in the hernial fack, and the ufe of violent and powerful aftringent medicines bringing on fuch a coftivenefs as never happens naturally. Violent commotions of the body in leaping, riding, or running, have been known fometimes to bring on the difeafe, as alfo violent fneezing and coughing, and the carrying of too great weights; as alfo crude foods, and fuch as have been indurated by fmoak, and flatulent and fermenting liquors. Sometimes alfo it has been evidently owing to worms killed in the bowels, and not voided by ftool.

Prognoftics in it. This is a very terrible difeafe, both in regard to the danger that attends it, and to the pain. In cafes where its origin is from a diftortion and convolution of the inteftines, there is very little hope of recovery; and when it arifes from a hernia, it is very often fatal alfo, efpecially when attended with an inflammation and plethora. Its mildeft ftate is when it arifes only from indurated ftools, and an obftinate coftivenefs; this is ufually cured, if proper affiftance be given in time.

Method of Cure. When a convolution of the inteftines is the caufe, the whole effort is to be ufed to explicate them; but this is a thing more eafily conceiv'd in the mind than effected; to this purpofe fome recommend the fwallowing of a mufket-bullet, others a globule of antimony, and others a pound of quickfilver, taking before-hand a fpoonful or two of oil of fweet almonds, and ordering motion by walking or riding afterwards; others advife the introducing the nofe of a pair of bellows into the orifice of the rectum, and blowing up into the inteftines; but as that gut is ufually fo conftricted in this cafe, as fcarce to admit the pipe of a clyfter apparatus, there is no great hope of fucceeding in the other attempt; and others finally advife the throwing in the fume of tobacco. The difcuffion of the inflammation is fcarce lefs neceffary than the other; this is to be done by powders of nitre, cinnabar, and crabs eyes, taken four times a day, and by rubbing the abdomen with camphorated fpirit of wine, in which faffron has been infufed; bags of carminative ingredients, with camphor, may alfo be applied to the abdomen with good effect: And finally, if there be a plethoric habit, bleeding is a very neceffary operation.

In cafes where this is occafioned by a hernia, the firft thing to be done is the reducing the inteftine into its proper place. To this purpofe the patient muft lie upon his back, and emollient and carminative fomentations muft be applied to the part, made of decoctions of marfhmallows, camomile flowers, and the feeds of anife fennel, and fœnugreek, boiled in milk; and, when there is no inflammation, fomentations of this kind may be applied in the manner of cataplafms, by wetting a fponge with them, and applying it to the part. An inflammation is carefully to be guarded againft, by nitrous medicines, and by gentle diaphoretics, and as foon as the gut is replaced, clyfters muft be given to bring on again a laxity of the bowels.

When the cafe only arifes from an induration of the fæces, there are firft to be given internally nitrous and cinnabarine medicines, to prevent or take off an inflammation, and at the fame time clyfters are to be given, with the emollient decoctions, and a little nitre and camphor, with fome oil; and if it be neceffary for a yet farther ftimulus, fome venice foap may be added; acrid fuppofitories are to be introduced into the rectum, and the foap plafter to be applied to the abdomen, or elfe fpirit of wine camphorated is to be rubbed in; bags with carminative ingredients may alfo be applied warm, and where the ftate is plethoric, bleeding is neceffary.

Thefe are the general methods, and ufually one or other of them takes effect in the milder cafes. But it is to be obferved, that honey, though ordered by fome, is never to be put into thefe clyfters, for where there is an inflammation, it promotes fuppuration. Clyfters of common warm water, with falt, have fometimes been found to have very great effect. The patient is to be kept warm during the courfe of the difeafe, and the diet is to be very fparing, though the drinking warm liquors is to be indulged. *Junker*, Confpect. Med. p. 574. feq.

MISERICORDIA,

MISERICORDIA *in Cibis & Potu*, in our old writers, is uſed for any gratuitous portion of meat and drink, given to the religious in convents beyond their ordinary allowance. *Matt. Paris.* And in ſome convents they had a ſtated allowance of theſe over-commons upon extraordinary days, which were called *Miſericordiæ Regulares*. Mon. Angl. T. 1. p. 149.

MISGUM, in zoology, the name of a fiſh of the anguilliform kind, but broader and flatter than the eel, and of much the ſame ſize from the head to the tail. It has five black lines, one on the back, two which are ſomewhat broader, in the middle of the ſides, and two others which are narrower lower down; theſe are all extended from the head to the tail. The intermediate ſpaces, and the belly, are of a ſomewhat bluiſh white, dotted with black ſpots. The fins are alſo ſpotted in the ſame manner. The mouth is ſmall and round, like that of the lamprey, and is ſurrounded with beards, ſix on the upper jaw, and four on the under. And there are two other very ſlender ones near the noſtrils. The eyes are ſmall; the gills four on a ſide; and beſide the back fin there are four, two near the gills, and two lower on the body. This is a common fiſh about the German ſhores, and is eſteemed a very delicate one at the table. It lays its ſpawn in March, and is in beſt ſeaſon for eating in January and February. It is caught principally in ſtanding and muddy waters; and it is ſaid, that when out of water, it makes a ſort of hiſſing noiſe. *Willughby*, Hiſt. Piſc. p. 119.

MISLETOE (*Cycl.*)—It has been formerly ſuppoſed that the *Miſletoe* was produced as a ſort of excreſcence from the tree it is found on; but time and experiments have ſhewn, that it is raiſed like other plants from ſeeds. Its berries are of a viſcous nature, and ſticking to the beaks of the birds that eat them, they may be rubbed off againſt the branches of other trees, and there take root and grow, but this is not neceſſary for their propagation, for the great numbers of plants of it uſually found on the ſame trees, ſeem to prove very plainly, that it is produced by the falling of its ſeeds, like all other plants, but that the matrix for theſe is not earth, but the branches of a living tree.

The trees on which *Miſletoe* is principally found, are the apple, the aſh, and other ſmooth-rind'd ones. It is very rarely found upon the oak; and though it may eaſily be propagated by its ſeeds on other trees, yet it has not been found to take readily upon the oak. *Miller*, Gardener's Dict.

Ariſtotle thought that *Miſletoe* was not a plant produced from ſeeds, but a mere excreſcence of the trees on which it was found, produced either by an extravaſation of the nutritive juices of the tree, or by a tranſpiration of it; and many authors who have written of it, have been of the ſame opinion. But Theophraſtus and Pliny were of opinion that it ow'd its origin to ſeeds, but that they muſt neceſſarily paſs through the bowels of a bird before they were in a condition to grow.

The ſeeds of *Miſletoe* are ſo ſoft, that one would imagine they would be digeſted by the ſtomach of a bird. Bonone, however, has obſerved, that they are voided entire; but there is no neceſſity of ſuppoſing their paſſing this ſtate, in order to their germinating. Malpighi has very perfectly deſcribed the ſeeds of *Miſletoe*; he ſays, that it germinates by puſhing out two horns from two of its angles; and Camerarius has made the very ſame obſervation. But the firſt account we have of *Miſletoe*'s being regularly raiſed by planting the ſeeds, is from Mr. Ray, who mentions its having been done by Mr. Doody.

The fruit of the *Miſletoe* are roundiſh ſoft berries, faſtened by a ſhort pedicle to the bottom of a fleſhy cup. That part of the berry which ſtands oppoſite to this pedicle, is ſomewhat flatted, and there may be ſeen there a ſmall ſhining brown body of an oval figure, which is that part of the piſtillum called by Linnæus, the *ſtigma*; and round about this ſtigma there are four longiſh marks, which ſhew the places where the leaves of the flower have been faſtened. The ſkin of the fruit, when ripe, is very ſmooth, tranſparent, and tough, and on examining it by the microſcope, it is ſeen very full of veſſels produced from the pedicle, and making frequent anaſtomoſes with one another. Within this is the ſeed wrapped up in a viſcous matter, and of a flatted ſhape, and greeniſh colour; they are beſt ſeparated from this viſcous matter by ſteeping in warm water, and are uſually found to be triangular, ſometimes oval.

When a berry of *Miſletoe* is cruſhed and broken againſt the bark of a tree, the viſcous matter which ſurrounds the ſeed ſoon dries away into a thick and tough ſkin, which ſurrounds the ſeed, and keeps it faſt down to the bark; but the rains frequently waſh theſe off afterwards, eſpecially when they have fallen upon the ſmoother part of the bark, or upon ſuch parts of a tree as are clean and free from moſs. And hence it is, that moſt of the *Miſletoe* we find, is either found upon the under part of the branch of a tree from whence the rain could not ſo eaſily diſlodge it, or on ſuch as have a rough bark, or are in part covered with the common tree-moſſes.

Mr. Du Hamel determined to inveſtigate the nature of this odd plant, put ſeveral of the ſeeds of it into ſmall ſlits, which he cut in the barks of different trees, by that means to defend them from being waſhed away by rains, and theſe all ſucceeded well and ſhot, except thoſe he planted on the fig, on which he made ſeveral unſucceſsful attempts; the miſchief done to the ſeeds by the milky juice of this tree, was probably the cauſe of this. It is no wonder that *Miſletoe* grows equally on all ſorts of trees, ſince there requires no more to make it grow than the effect of the rains and night dews; and this author found the ſeeds ſhooting on earthen pots and ſtones, which he kept ſhaded from the heat of the ſun; and from parallel experiments it ſhould ſeem alſo, that the tranſpiration of trees helps greatly the germination of theſe ſeeds.

The ſeeds of *Miſletoe* ſown, if we may ſo call it, on the bark of trees in February, begin to ſhoot in June, and at that time there are ſeen two little round bodies iſſuing out at the two angles of the triangular ſeeds; but as theſe ſeeds are ſubject to ſome irregularities in their figure, ſo they alſo are in their germination, for from the oval ſeeds there is only one ſhoot, and from thoſe which are irregularly angular, there are ſometimes four or five.

Each of theſe round bodies is faſtened to a pedicle, which has its inſertion in the fleſhy part of the ſeed, in which there are a ſort of grooves, which make it ſeem as if theſe pedicles came out of a ſort of caſe.

This ſort of germination is peculiar to *Miſletoe*, no other ſeed ſhooting out ſo many radicles. Theſe alſo are often found of very different lengths, tho' coming from the ſame ſeed, nor do they all appear at the ſame time, but ſeem to vegetate differently and diſtinctly.

The length of theſe radicles is in a great meaſure owing to the poſition of the ſeed on the branch of the tree, for they always grow in length till they reach the bark; ſo that if the ſeed be ſo placed that the germ iſſues out cloſe to the tree, it is proportionably ſhort; but if it happens to proceed from the upper part of the ſeed, it bends and grows in length till it reaches the bark to which it is to be fixed.

Mr. Du Hamel, willing to try how far this elongation of the radicle might be carried, placed two ſeeds of *Miſletoe*, which had already germinated, upon a ſmall ſupport, raiſing them from the branch of the tree. In the one of theſe the radicle was turned toward the branch, tho' at an unnatural diſtance, in the other it was directed a contrary way. The conſequence was, that the firſt grew to twice its natural length, and then the blackneſs of the round body at the end ſhewed it began to decay; after which it grew no more; the other turned its germ back to the ſupport, and fixing there, periſhed for want of nouriſhment. Another time, making a hole in the branch of a nut-tree, juſt when the radicle of a *Miſletoe* ſeed was ſtriking, he cauſed the radicle to grow to twice its natural length, and it finally reached the bottom of the hole, and ſtuck there, and produced a vigorous plant. It is to be obſerved alſo, in regard to the germination of theſe ſeeds, that they are the only ones in which the radicle takes indifferently any direction, in all other ſeeds it points ever downwards only.

The ſeeds of *Miſletoe* will ſhoot equally well on the upper and under ſides of a branch of a tree, and thoſe on the upper will bend their radicles downward, while thoſe on the under will ſtrike theirs directly upward with the ſame eaſe.

The radicles of *Miſletoe* are, as has been already obſerved, compoſed of a little round body, ſuſtained by a pedicle. When this pedicle has grown to ſuch a length that the round body touches the bark, it opens before into the ſhape of the trunks of flies, and other inſects, and by this means touching cloſely at all its edges, it becomes faſten'd extremely firm to the tree. From this reſemblance in ſhape to the trunks of ſmall animals, Dr. Du Hamel calls theſe radicles the trunks of the ſeed of *Miſletoe*. The ends of theſe trunks of the radicles are alſo faſtened to the bark of the tree by a viſcous matter, which, when the trunk is gently raiſed, draws out into ſtrings on all ſides to ſome length.

In the inner part of this trunk, or open button, there are two ſubſtances to be diſtinguiſhed; in the center there is a white granulated matter, and round that a greeniſh one; both theſe are juicy, but the outer leſs ſo than the central white part; the outer one is plainly the ſame with the outer rind of the root of the *Miſletoe*, or the ſecond bark of its trunk. Theſe both very quickly adhere to the tree, ſtriking their ſeveral granulæ into it, and theſe furniſh afterwards the roots of the *Miſletoe*.

The outer bark of *Miſletoe* is thin, of a deep green, and ſomewhat rough; it is ſtronger than that which it covers; and this is not extended to the roots of the plant, but ſpreads over the bark of the tree at the bottom of the ſtalk, juſt as the feet of the corals and other ſea plants do over ſtones. The viſcous matter, by which the trunk adheres to the tree, is furniſhed from all parts of the radicle, but principally from its outer bark, and is not at all owing to the juices of the tree, ſince it is found as abundantly on thoſe radicles which have been made to adhere to ſtones, as on thoſe which have been on trees. A little time fixes theſe trunks very firmly; but it is obſervable, that though the outer bark or edge of theſe open balls adheres equally all round to the bark of the tree, the granulæ of the inner ſubſtance always direct themſelves to and inſinuate in the little clefts or cracks of the rind of the tree. While the ſeeds of *Miſletoe* are in this ſtate, they may be tranſplanted to other places, and ſet on other trees, and ſeldom fail to thrive.

Seeds of this plant may be made to ſhoot on ſtones, and will fix their trunks to them, but here they naturally ſoon periſh; they may however be removed from theſe ſtones to the

branches of trees, as ſoon as they have affixed themſelves, and being then in a ſtate of drawing nouriſhment, they will affix themſelves to the tree, and from its juices begin to thrive immediately.

It has been very naturally ſuppoſed by thoſe who thought the *Miſletoe* no perfect plant, that it had no roots, nay even thoſe who allowed it to be a perfect plant, and produceable from ſeeds, yet have ſuppoſed it had no root. Malpighi, however, affirms that he plainly ſaw its roots. And Tournefort countenances the ſame opinion; but neither of theſe authors have perfectly deſcribed them.

In that part of the branch of a tree where the *Miſletoe* grows, there is always obſerved a thickneſs, and the bark is always chopped in ſeveral places; but the roots of the *Miſletoe* are by no means to be ſeen externally, being hid both by the bark of the tree, and by the expanſion of the bark of the plant itſelf at its bottom. It is neceſſary, therefore, for the diſcovery of the roots, to raiſe very nicely both the bark of the plant, and that of the tree; but the hardneſs of theſe barks, and their ſtrict attachments to the roots, makes this difficult; and there is indeed no way of ſucceeding well in the attempt, but by boiling the part in water, and making nice diſſections of it before it is cold. By this means the bark of the *Miſletoe*, and that of the tree, are both eaſily raiſed, and the roots of the *Miſletoe* are found partly inſerted into the bark, and partly into the wood of the branch.

The bark of trees is a ſubſtance compoſed of ſeveral beds or ſtrata, the upper or outer of which is an extremely thin one, and the others, which are thicker, are formed by the extenſion of the woody fibres, which run longitudinally into a ſort of network, the cells of which are filled with a parenchymatous ſubſtance. This is the ſtructure of all the barks of a tree, except the outer thin one; but of theſe, thoſe are always the moſt ſucculent and rich which lie innermoſt, or neareſt the wood of the tree.

It is obſervable, that when an inſect wounds the bark of a tree or plant, there is always a greater derivation of the juices to the wounded part than elſewhere, and hence galls and other protuberances are formed; this ſeems alſo the caſe here, and the application of the trunk of the *Miſletoe* ſeed, and the penetration of its roots ſeem alſo to wound the part ſo much, as to cauſe in the ſame manner a derivation of a great quantity of juices for the nouriſhment of the young plant: And as the roots ſtrike deeper in, there is made a greater extravaſation of the juices of the tree, and a ſort of tumour is neceſſarily formed.

Among the ſeveral roots of the *Miſletoe*, there are ſome which extend themſelves among the more ſucculent parts of the bark, and others which penetrate to the wood of the branch. Theſe ſpread themſelves every way with great eaſe, as they are principally formed at a time when the tree is full of ſap.

It has been ſuppoſed by many, that the roots of the *Miſletoe* penetrated the woody ſubſtance of the tree; but though appearances make greatly for this ſyſtem, it is by no means true in fact. The roots of the young plants, when they have penetrated through all the lamina of the bark, and reach the wood, turn off, as the roots of plants do which meet with ſtones, *&c.* in their paſſage, and ſpread horizontally between the inner bark and wood, or elſe re-aſcend the bark, the looſe and juicy nature of which is much fitter for affording them nouriſhment than the hard ſubſtance of the wood. It is true, that in making ſections of the branches where old plants of *Miſletoe* grow, there are often found roots, nay ſometimes even the woody ſtem of the plant plunged into the matter of the hard wood; but this is merely owing to the inner bark of the branch having become woody ſince the penetration of the roots, not to the roots finding their way into what was actual wood at the time.

There are alſo found always a multitude of woody excreſcences, like warts and wens, about the place where the *Miſletoe* grows; theſe are formed like the woody galls produced on trees by the punctures of inſects, by an extravaſation of the woody juices. Theſe make the ſwelling about that part of the branch where the *Miſletoe* grows, and theſe, as they become woody, and ſwell about the roots, ſerve to cover them with hard wood, which they never penetrated. Theſe make it probable enough that the roots of *Miſletoe* never penetrate hard wood; but what proves it much more evidently, is, that if the branches of trees full of *Miſletoe* plants be cut and ſplit in different directions, juſt at the place of the inſertion of the plant, the ſeveral annual circles of the wood within are found perfect, regular, and in their natural ſtate, ſo far as the branch was form'd at the time the *Miſletoe* took root upon it; theſe ſhew the age of the branch at that time, but above theſe there are always ſeveral other laminæ, which are what have been formed ſince the time of the *Miſletoe*'s growing there; and theſe which have been formed out of the inner laminæ of the bark, in which the roots of *Miſletoe* had made many wounds and great extravaſations of the juices, are found, tho' woody, full of the roots of the plant, and are very irregular, and full of the tubera which thoſe extravaſations occaſion, by by no means appearing like the annual circles of the wood formed before. The ligneous fibres in the outer, or ſince form'd wood, are laid in very irregular directions, and the roots of the *Miſletoe* may be eaſily diſtinguiſhed among them by their colour.

The *Miſletoe*, as the bark in which its roots were ſpread, hardened into wood, would be in the ſtate of a tree, planted in an earth which, by degrees, petrified about it, and muſt periſh; but nature has provided for it in this caſe; for as theſe roots are impriſon'd in wood, and a new bark is formed by the ſap of the tree, the trunk of the *Miſletoe* ſends out a new ſeries of roots, which ſpread thro' this in like manner; ſo that tho' a plant of *Miſletoe* has ever ſo many ſeries of its roots embodied in the hard wood, from which it can have no nouriſhment, it has alſo ſome, ſufficient for its ſupport, ſpread among its yet new-form'd bark.

The *Miſletoe* is frequently found in this ſtate; nor are we to ſuppoſe, indeed, that tho' the wood is not able to furniſh ſo much juice as the bark, that it furniſhes none at all; for the roots of the plant do not decay, when they have penetrated what afterwards becomes perfect wood; even in its hardeſt ſtate, they are ſtill found perfect in it, and in a living ſtate, and undoubtedly furniſh ſome, tho' not a great deal of nouriſhment to the plant. Another thing very remarkable in thoſe plants of *Miſletoe*, many of the roots of which are lodged in the hard wood, is, that the roots diffuſed through the bark have often a large tubercle at their ends, which probably is furniſhed with numerous openings for the receiving the juices the plant is to be nouriſhed by, and ſerves in the place of many roots.

There are ſometimes indeed found plants of *Miſletoe* which live wholly by the nouriſhment they receive from the wood; theſe are in the ſtate of grafts of common fruit-trees; but theſe are rare, and it very ſeldom ſucceeds when the *Miſletoe* is attempted to be propagated by the common method of grafting, though the plants of *Miſletoe* may very eaſily be grafted by approach into one another.

A farther circumſtance worthy obſervation, is, that tho' ſome plants of *Miſletoe* have been found growing very well with their roots only in the wood, yet this is generally fatal to them, and many plants of it are found dead and wither'd, by means of the woody part of the tree riſing into a ſort of wen or tubercle about them, and by its cloſely ſurrounding their ſtalk, preventing all intercourſe with the bark, by means of new roots. This is uſually the caſe when the plants of *Miſletoe* are weak, and the branch on which they grow very ſtrong and vigorous; and on the contrary, when the plants are very ſtrong, and the branch weak; in which caſe, the roots of a large *Miſletoe* plant will ſometimes penetrate the whole round of the bark, and taking in all the nouriſhment to itſelf, the end of the branch beyond it will periſh and rot off; but the *Miſletoe*, in this caſe, is not able to ſupply the place of the ſtarved part of the branch, but the remainder of the bough generally dies quite to the trunk of the tree, and the *Miſletoe* periſhes with it.

Though this plant is evidently propagated by its ſeeds, yet it alſo propagates itſelf very often by ſuckers, and it is not uncommon to find young ſhoots at a finger's breadth or two from the old one. The gardeners, who value their trees, are very careful to deſtroy the *Miſletoe* from them, and that very properly, ſince it is extremely obvious from what has been obſerved, that it robs the tree it grows on of a great deal of its nutritious juice. The common method of cutting off the plants to this purpoſe, is, however, by no means ſufficient; for the old ſtock frequently puſhes out new ſhoots, and the roots afford ſuckers, ſo that the caſe becomes worſe than before. There is indeed no way of deſtroying it, but the cutting away with it a part of the turbercle it forms on the branch where it grows.

The roots of *Miſletoe*, while young, are green, very tender, and granulated, as is alſo the bark of the older ones; but theſe have a woody filament within. They are not regularly round, but are often flat, and uſually adapted in their ſhape to the place where they are lodged; and about their inſertions it is not unfrequent to ſee a ſort of elongation of their bark, which blends itſelf with the bark of the tree on which they grow.

The progreſs of the branches of *Miſletoe* is much ſlower than that of the roots. The firſt year, and often the ſecond, is ſpent wholly on their part, in the raiſing themſelves into an erect poſture, and very often this operation proves fatal to them.

The ſeeds, as has been before obſerved, faſten themſelves to the branches of trees, by means of the viſcous juice contained in the berries. The radicles produced hence affix themſelves, by means of the hollow button at their extremity, to the bark of the tree; and the other end being yet held faſt in the ſeed, the whole proceſs forms a ſort of arch. When the button end of the radicle has got itſelf good root in the bark of the tree, and begins to ſend up ſap in abundance into its pedicle, which is to be the ſtalk of the plant, that by degrees begins to looſen itſelf from the ſeed; and this is often a work of great difficulty; for the ſeed being firmly attached by its viſcous matter now dried to the bark of the tree, holds down the end of the ſtalk, that very often the force of riſing in the young plant is not enough, and it remains in its arched form, and periſhes; and often

often the open end is forced away from its hold on the bark by the reſiſtance, and the young plant dies.

Thoſe ſhoots which are ſingle from ſingle ſeeds are ofteneſt deſtroy'd at this juncture, for they have ſingly the force of the whole ſeed to ſtruggle againſt, and when they ſucceed, uſually raiſe it up, and keep it on their extremity; but where the ſame ſeed ſends three or four radicles, theſe all ſtruggle ſo many different ways to riſe, and the huſk of the ſeed is uſually torn, by their efforts, into three or four pieces; and every radicle carrying its portion on the top, becomes a diſtinct plant. It might ſeem from this, that the feminal lobes were neceſſary to the growth of the young plant; but this is not the caſe, for if the ſtalks of the ſeveral radicles are cut off while they adhere to the ſeed, they thrive not at all the worſe for it.

It is a very ſingular circumſtance in this plant, that its ſeeds produce ſingly ſeveral young plants. No other vegetable has this property. 'Tis true, indeed, that two young hazels have been ſeen to riſe from the ſame nut; but then we know very well, that nuts have frequently double kernels in the ſame ſhell; but here the ſeed is contained ſingly in a berry, and, to all examination, appears of a ſimple uniform ſtructure, tho' it doubtleſs is compoſed according to the number of young plants it will produce, of three, four, or more perfect ſeeds.

When the young plant of the *Miſletoe* ſeed has freed itſelf from the huſk at its end, and raiſed itſelf upright, it is found terminated at the end by a ſort of button, like that of other young ſhoots, which contain the leaves. This button ſtands, however, unalter'd all the firſt year, and ſometimes all the ſecond; in the ſpring following there appear from the button two leaves, and in the alæ of theſe leaves there are ſeen two other buttons; and afterwards there iſſue from theſe buttons branches terminated uſually by two, but ſometimes by three leaves. Theſe are the produce of the third or fourth year; all the ſucceeding years there are new buttons formed in the alæ of the leaves, and the branches from theſe expand themſelves ſo regularly, that very frequently the whole ſhrub is of a regularly round figure.

The old leaves become yellow, and fall off, and there come no new ones in their places, ſo that the old ſtalks, and conſequently the whole inner part of the plant is naked, and the leaves are only found on the circumference growing on the young branches.

It is a remarkable obſervation, that every button of the *Miſletoe* contains the rudiments of three young branches, and hence every knot ought to be furniſhed with ſix branches; and this would ever be the caſe, but that ſeveral of the young branches die either before, or ſoon after their emerging from the button.

Among the other ſingularities of this plant, it is alſo worthy obſervation, that its ſtalks have not that tendency natural to thoſe of all other plants, of riſing directly upwards; for if it grow on the under part of a branch of a tree, it ſhoots as regularly downwards, as it does upwards when it grows from the other ſide, and this without ſeeming at all to ſuffer by it, or to have any inclination to turn upwards.

Some of the old authors have ſaid, that the *Miſletoe* kept its leaves all the winter, when it grew on an ever-green tree, but that when the leaves fell from the tree it grew on, its leaves fell alſo; but this is erroneous, *Miſletoe* holding its leaves all the year, on whatever tree it grows, and ſtanding unhurt in the ſevereſt winters.

Miſletoe will grow on all kinds of trees; but it does not grow on all with the ſame ſtrength and vigour. The pear, the apple, the white thorn, and the lime, are trees it grows on very ſucceſsfully. The oak, the hazel, and the juniper, are very ſtarving for it. Mr. Du Hamel could never make it ſucceed by ſowing on the laſt of theſe trees; but it has ſometimes been found naturally propagated on it, tho' in a ſtarving condition. It will alſo grow on annual plants, but on theſe it never can come to any height, as their ſtalks periſhing at the approach of winter, the *Miſletoe* periſhes with them. Mr. Du Hamel took great pains to ſow and try to raiſe it on the ground, and ſucceeded ſo well as to make the ſeeds ſhoot, and their radicles grow to ſome length; but finding no proper hold to fix themſelves upon, they all periſhed; whence it ſeems that this is abſolutely a paraſitical ſhrub, and can grow no where but on ſome other tree.

The *Miſletoe* is covered with two barks, an external thin one of a greeniſh colour, and ſomewhat wrinkled and granulated; and under this with a much thicker, of a paler green, and ſomewhat granulated, and interſperſed with woody fibres. Under this lies the wood, which, when dry, is very hard, but has no appearance of any grain, and cuts with equal eaſe in a longitudinal or tranſverſe direction. The ſtalk between every two knots is perfectly ſtrait, but at the knot it takes great inflections. Each of theſe pieces of the ſtalk in ſome meaſure repreſents the tibia of the human leg, being a little larger at one end than at the other, and always much ſmaller in the middle than at either extremity. It joins the ſucceeding ſtalk not in the common manner of vegetables, but by a ſort of articulation, and has a ſort of epiphyſes like the bones. The analogy is carried alſo yet farther, in that as in young animals the epiphyſes of the bones are all ſoft and tender, but harden in older ones; ſo in this plant the young branches ſeparate eaſily at their articulations, but in the old ones theſe are as hard as any other part of the ſtalk.

The leaves of *Miſletoe* are thick without being ſucculent, their pedicle is very ſhort, and there run from it four or ſix longitudinal ribs, which reach the outer end of the leaf without making any obſervable ramifications.

Miſletoe is a very vigorous and lively plant, and is one of thoſe to which nature has allotted males and females in diſtinct plants of the ſame ſpecies. Authors however are not perfectly agreed as to the manner of this. Pliny abſolutely affirms, that there are two ſorts of *Miſletoe*, the one which bears fruit, and the other which never does. And Mr. Edmund Barrell greatly confirms this opinion by his own obſervation, giving an account that he raiſed four plants of *Miſletoe* from ſeeds, two of which bore fruit, but the other two only flowers. Mr. Tournefort, Linnæus, and Boerhaave, however, affirm, that the flowers and fruit are not produced in different plants, but on the different branches of the ſame individual. The matter thus remained doubtful till Mr. Du Hamel determined to enquire thoroughly into the truth; and his obſervations wholly confirmed thoſe of the antients, and of Mr. Barrell. Nay, he adds, that the whole habit of the male and female plants of the *Miſletoe* is ſo different, that they are eaſily known aſunder, without having recourſe to their flowers, or fruit; and he never found, in all his obſervations, ſo much as a ſingle flower on a female plant, or a ſingle berry on a male one.

The buds which contain the male flowers of *Miſletoe* are rounder than thoſe which contain the female flowers, or the embryo fruit, and are three times as large. The buds ſhew themſelves diſtinctly on the branches in autumn, and in December they are of a conſiderable ſize, tho' not at all inclined to open; and the female plants are yet full of the berries of the former year. The male buds uſually grow three and three on the ſame pedicle, and they open in February or the beginning of March. Their flower is of one regular piece, forming a ſort of open bell; it is cut into four parts, the notches going down to the middle of the flower, and the ſegments being ſo many half ovals. There are four thick oval bodies, or four granulated ſhoots which are attached to the inner part of the bell, and which riſe over its lips; they are greeniſh at firſt, but they afterwards become yellow; theſe are full of an extremely fine powder: Theſe are truly the ſtamina of the *Miſletoe*, and that part of them which to the naked eye appears granulated, is by the microſcope found to be formed into a multitude of ſlight cavities, like thoſe of the morel. The flowers are placed in cluſters ſix or ſeven together, either in the alæ of the branches, or at their extremities; and having done their office, they fall off in May. The female plants have their flowers in the ſame places, but theſe have only three or four at a joint; they open at the ſame time that the male flowers do, on the other plants: When theſe flowers are perfectly opened, we ſee the embryo fruit crowned with four petals, which are planted in a ſort of cleft that runs all round the fruit, and which becomes more and more diſtinguiſhable as the fruit grows larger.

Theſe petals are at firſt united at their tops, and form a ſort of cone, but they ſoon after open and ſhew the figure of an antique crown; and there is then ſeen in the middle a ſort of rough eminence granulated like the peel of an orange, and of a browniſh colour. That part of the fruit which is below the inſertion of the petals grows much faſter than that which is above them, ſo that when theſe are grown to a conſiderable ſize, the petals ſeem placed merely upon them.

By the beginning of June almoſt all the petals are fallen, but the four inſertions remain however very diſtinguiſhable on the berry; and we may obſerve on their tops, as they are now about as big as a grain of hempſeed, a brown eminence which is the remains of the rough protuberance contained within the petals; and, on cutting them, the ſeed is found in the middle, of a greeniſh colour; the berries continue growing all July and Auguſt, and are ripe in September or October. Mem. Acad. Par. 1740.

MISOPTOCHOS, the *Beggar-hater*, an affected name given by ſome to the gout, a diſeaſe that ſeldom invades the poor or induſtrious.

MISSA, in the church of Rome. See the article MASS, *Cycl.*

MISSEL-*Bird*, in zoology, the common Engliſh name of the larger ſpecies of thruſh, called alſo the *ſhrite*, and by authors the *turdus viſcivorus major*. It is much larger than any other of the thruſh-kind. Its legs and feet are yellow; its head of a browniſh lead colour; and its back, tail, and rump, of the ſame colour, with an admixture of yellow; but in the ſummer months it a little changes its colour, and becomes more grey or of the colour of unripe pickled olives; its throat, breaſt and belly, are all variegated with black ſpots; the middle of its belly whitiſh, and the upper part of its breaſt and part of its ſides and the under feathers of its tail yellowiſh. *Ray's* Ornithol. p. 138.

It uſually is ſeen on the top branches of tall oaks, elms, and other high trees, and ſings very ſweetly. It remains the whole year with us, and flies ſingly, except with its female. It is the beſt of all the kind for the table.

MISSILIA, among the Romans, a name given to largesses, thrown among the people on occasion of games and shews, such as small gold or silver coins, sweet-meats, and sometimes animals, as sheep, oxen, deer, &c. which were let loose to be carried off by the people. *Hofm.* Lex. in voc.

The word comes from *mittere*, to throw, or let loose.

MISSING *Wood*, a phrase used among bowlers. See the article Bowling.

MISSION, *Missio*, among the Romans, a term used to signify the emperor's sending to rescue a wounded gladiator from his antagonist. The *Munerarij* or persons who exhibited the games, and likewise the people, used to rescue a favourite gladiator. The manner of their signifying this favour, was *pollice presso*, or with the thumb hid in the palm of the hand. However the gladiator was only saved for that time; whereas by the *Rudis* he had a free discharge. *Hoffm.* Lex. in voc. See the article Rudis.

MIST (*Cycl.*)—The bluish *Mist* which we sometimes see on our fields and pastures in a morning, though often innocent, yet has been in some places found to be the actual cause of murrain, and other fatal diseases among the horned cattle.

Dr. Winklar gives, in the Philosophical Transactions, an account of a murrain affecting the cattle in Italy and other places, which was evidently seen to spread itself over the countries in form of a blue *Mist*. Wherever this was perceived, the cattle were sure to come home sick; they appeared dull and heavy, and refused their food; and many of them would die in four and twenty hours. Upon dissection there were found large and corrupted spleens, sphacelous and corroded tongues; and in some places those people who were not careful of themselves in their management of their cattle, were infected and died as fast themselves. The principal cause of this disease seemed to be the exhalation of some unwholesome steams from the earth; and it was observable, that there had been three earthquakes in Italy the year before it happened. The method of cure which succeeded best, was this: As soon as any beast appeared to be sick, they examined the tongue, and if aphthæ or little blisters were found on it, they scraped it with a silver instrument made with sharp teeth at the sides, till it bled in all those parts where the aphthæ were; the blood was then wiped away with a cloth, and the whole tongue washed several times with vinegar and salt. After this the following medicine was given internally: Take of soot, brimstone, gunpowder, and salt, of each equal parts; mix these in as much water as will make a mixture thin enough to be swallowed, and let a spoonful be given for a dose three or four times a day. The cattle which were in health had this medicine given them, as well as the sick; and the consequence was, that very few died in Swisserland, while almost all died in other places.

It was very remarkable that the contagion, on this occasion, seemed to travel slowly and regularly on: It came at the rate of about two German miles in twenty-four hours: This it kept regularly to during the whole time of its raging, and never appeared in very distant places at the same time.

The whole surface of the earth emitting these effluvia, no cattle escaped them in the course of their way, but those which were kept within doors at rack and manger fell ill at the same time, and in the same manner with those in the open fields. Dr. Slare was of opinion, that it was owing to certain insects which could not fly faster than at the rate of two German miles a day; and that they travelled regularly, and spread the mischief where they passed; but there wanted some judicious persons, versed in these observations, to have examined both the state of the air, and the beasts, on this occasion. Philos. Transf. N°. 145.

MISURER, in our old writers, an abuse of any liberty or benefit: As he shall make fine for his *Misurer*. Old. Nat. Br. 149.

By *Misurer*, a charter of a corporation may be forfeited; so also an office, &c. *Blount*, *Cowel*.

MISY, (*Cycl.*) in natural history, the name of a fossile substance, used very frequently by the antients in medicine, and supposed to be one of their now lost medicines, but erroneously; it being still very common in the Turkish dominions, and not unfrequently found in the mines at Cremnitz in Hungary. It is a considerably firm substance, tho' of an irregular and seemingly not compact texture, and much resembles some of our gaudy marcasites; but that it wants their hardness and their weight, and is not inflammable.

It is commonly found in large loose masses, which are usually broad and flat, and uneven at their edges; but sometimes it constitutes whole strata, which are continued often for a considerable length, but are seldom of more than three inches in thickness, and usually lie like horizontal veins among other metallic minerals. It is soft and smooth to the touch, and may be rubbed to pieces between the fingers; and is both on the outside and within of a very elegant bright pale yellow, having much the appearance of brass, when that metal is clean and well scoured. Its internal substance seems made up of numbers of very bright and small moleculæ, mostly of angular figures. It is never covered with any investient coat or crust; but when it has lain some time exposed to the air, it becomes of a duskier colour than before on the surface. It will not raise any effervescence with acid menstrua, and in the fire becomes of a deep purple. Water dissolves a very considerable part of its substance, and this may afterwards be separated from the liquor by evaporation and crystallization, and appears to be of the same nature with the common green vitriol: Its crystals being exactly of the same figure, and their effect upon a decoction of galls being the same, instantly turning it into ink. It has so much of the appearance of a sulphureous body, that one is surprised not to find it inflammable. *Hill's* Hist. of Fos. p. 606.

It is at present no where put to any use. The antients esteemed it of the same nature with the chalcitis, but that it possessed those virtues in a more remiss degree; they had it from Ægypt and Cyprus, and used it externally in hæmorrhages, and some cutaneous eruptions.

Misy, in botany, a name given by Theophrastus, and all the old Greek writers, to a kind of truffle or subterranean mushroom, of a very delicate flavour. The truffles of Numidia, and some other parts of Africa, were always esteemed superior to those of any other part of the world. They are called *terfez*, *camaha* or *kema*, by some later writers, and were brought to Rome, and so greatly esteemed, that no dish was ranked above them. These were called Libyan truffles by the Romans, and they seem to have been the same with the Cyrenian *Misy* of the Greeks. It is to be observed, that the Greeks in general, in early times, were very little acquainted with the affairs of Africa; and all that they had from this part of the world, was said to come from Cyrene, some old cities of their forefathers being there, and keeping up a friendship and traffic with them. The *thyon*, a tree growing plentifully in almost all parts of Africa, and which is the same with the citrus of the Romans, was in this manner attributed to Cyrene, by the same Theophrastus. And thus, when speaking of truffles, he adds, that the Cyrenean *Misy* surpassed all the other kinds in flavour; his words stand at large in Athenæus; and thence Pliny has taken his account, which he closes in this manner: "The thing which they call *Misy*, in "the province of Cyrene, is of this kind; but it is more fleshy "and of a finer taste and smell." This is the sense of Pliny, as the text stands in our copies; but it is probable that he translated Theophrastus better than they, at least as we know that what he says is not his own, but taken from that author, we have a right to understand it his way, and that is, that the roots of this Cyrenean *Misy* have a delicate smell resembling that of meat, or flesh newly cut. *Pliny*, L. 19. c. 3.

It is very certain, that this Cyrenean *Misy* of the old Greeks is the same thing with the delicate African truffle or terfez of LeoAfricanus, and the moderns; and Pliny had read some of the antients who were sensible of this, and has taken from them an account that the African truffles are the finest in the world; and yet did not perceive, that these African truffles were the same with the Cyrenean *Misy*, which he immediately after mentions from Theophrastus.

MITE, (*Cycl.*) in natural history, the name of a small animal, very well known and found in old cheese, and in many other bodies both recent and perishing.

To the naked eye the *Mites* in cheese appear like moving particles of dust, but the microscope discovers them to be perfect animals, having as regular a figure and performing all the functions of life as perfectly as creatures that exceed them many times in bulk. See Tab. of Microscopical Objects, Class 1.

They are crustaceous animals, and are usually transparent; the principal parts of them are the head, the neck, and the body. The head is small in proportion to the body, and has a sharp snout and a mouth that opens and shuts like a mole's. They have two small eyes, and are extremely quick-sighted; and when you have once touched them with a pin, you will easily perceive how cunningly they avoid a second touch.

They are of different sorts; for some of them have six legs, and others have eight. Each leg has six joints surrounded with hairs, and two little claws at the extremity, with which it very nicely takes hold of any thing. The hinder part of the body is plump and bulky, and ends in an oval form, from which there issue out a few exceeding long hairs. Other parts of the body and head are also beset with thin and long hairs.

The males and females are easily distinguished in these little animals. The females are oviparous as the louse and spider, and from their eggs the young ones are hatched in their proper form, without having any change to undergo afterwards. They are however, when first hatched, extremely minute; and, in their growing to their full size, they cast their skins several times.

These little creatures may be kept alive many months between two concave glasses, and applied to the microscope at pleasure. They are thus often seen *in coitu*, conjoined tail to tail; and this is performed by an incredibly swift motion. Their eggs, in warm weather, hatch in twelve or fourteen days; but, in winter, they are much longer. These eggs are so small, that a regular computation shews, that ninety millions of them are not so large as a common pigeon's egg. *Baker's* Microscope, p. 187.

Mites are very voracious animals; they not only prey upon cheese, but on all sorts of dry'd flesh, fish, fruits, and seeds; and almost on all things which have some degree of moisture, without

without ever being wet; and they have often been feen to eat one another. Their manner of eating is by thrufting alternately one jaw forward and the other backward; and in this manner grinding their food; and after they have done feeding, they feem to chew the cud.

There are feveral leffer diftinctions obfervable in the *Mites*, which are found among different fubftances. Thofe in malt-duft and oatmeal, are much nimbler than the cheefe *Mites*; and have more and longer hairs. The *Mites* among figs refemble beetles, and have two feelers at the fnout, and two very long horns over them; thefe have only fix legs, and are more fluggifh than thofe in malt-duft. Thofe found among figs had alfo very long hairs, and thofe befet at certain diftances with other fmaller hairs; whence Mr. Lewenhoek conjectures, that thefe longer and larger hairs are jointed at thofe places where the fhort ones are found.

There are a fort of wandering *Mites*, found wherever there is any thing they can feed on; thefe are often found in form of a white duft, and are not fufpected to be living creatures.

The *Mite* is an animal very tenacious of life; it will live months without food; and Mr. Lewenhoek had one which lived eleven weeks on the point of a pin, on which he had fixed it for examining it by his microfcope. *Lewenhoek*'s Arcan. Nat. T. 4. p. 368.

MITELLA, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the rofaceous kind, confifting of many petals difpofed in a circular form. The piftil arifes from the cup of the flower, and finally becomes a roundifh and pointed fruit, which when ripened fplits into two parts, and in fome degree refembles a mitre, and contains ufually roundifh feeds.

The fpecies of *Mitella*, enumerated by Mr. Tournefort, are thefe: 1. The American *Mitella*, with fimbriated petals. 2. The American *Mitella*, with whole petals. 3. The great American dying *Mitella*, called *Orellana*, *Achiotl*, and *Wruow*. Tourn. Inft. p. 241.

MITELLA, in furgery, a name given to the fcarf for fufpending the arm when injured.

MITHRIDATES, in natural hiftory, the name of a ftone found in fome parts of Perfia, feeming to be the fame as the *mithridax* or *mithrax*. See the next article.

MITHRIDAX, in natural hiftory, the name of a gem defcribed by Solinus, and mentioned by fome of the later writers, who have quoted him, or borrowed from him; but the name is not met with in any author earlier than his time. The qualities he beftows upon it, are the fame with thofe given by Pliny to the *mithrax*; and as the word *mithrax* never occurs in Solinus, it is highly probable that he means this ftone by it. He fays, that when the fun fhines upon the *Mithridax*, it fhews a great many various colours.

Ifidore fays the fame thing, evidently borrowing the account and almoft the words from him.

Pliny tells us, that the *mithrax* has the fame quality, and that it is in itfelf whitifh. Its name is taken from the Perfian word for the fun, and is the fame as *gemma folis*. Pliny indeed, in the latter end of his book, defcribes a ftone called *folis gemma*, without faying that it is the fame with the *mithrax*; but his accounts in both places agree very well one with another; and the common cuftom of that author of collecting at large from all the writers of his time, might eafily lead him to defcribe a thing twice, which he found in two authors called by two different names.

The *mithrax* both of Pliny, and all the other antients, is evidently the opal; and the *Mithridax* having no other qualities attributed to it, but thofe the opal poffeffes, may be determined to be only a corruption of the fame name.

MITHRAX, in natural hiftory, the name given by Pliny and the antients, to a gem found in Perfia, which when held up to the fun fhewed many colours. It was probably no other than the opal. Hence the barbarous writers of the middle ages feem to have taken their account of the *Mithridates*. See the preceding article.

MITRE (*Cycl.*)—*Mitre* is ufed by the writers of the Irifh hiftory for a fort of bafe money, which was very common there about the year 1270; and for thirty years before, and as many after. There were befide the *Mitre*, feveral other pieces called according to the figures impreffed upon them, rofaries, lionades, eagles, and by the like names. They were imported from France, and other countries, and were fo much below the proper currency of the kingdom, that they were not worth fo much as a half-penny each. They were at length decry'd in the year 1300, and good coins ftruck in their place. Thefe were the firft Irifh coins in which the fcepter was left out. They were ftruck in the reign of Edward the fon of our Henry the Third, and are ftill found among the other antiquities of that country. They have the king's head in a triangle full-faced. The penny, when well preferved, weighs twenty-two grains; the half-penny ten grains and a half. *Simon*'s Irifh Coins.

MITTA, in our old writers, an antient Saxon meafure. Its quantity is not certainly known; but it is faid to be *menfura decem modiorum*, a meafure of ten bufhels. *Doomfday*.

Mitta, or *Mitcha*, befides being a meafure for falt and corn, is ufed for the place where the caldrons were put to boil falt. *Calderias quoque ad fal conficiendum cum propriis fedibus* Mitchæ *vocantur*. *Gale*'s Hift. Brit. 767. *Blount*.

MITTENDARII, among the Romans, commiffioners fent into the provinces by order of the *præfectus prætorio*, or captain of the guards, upon fome public account, as to infpect the behaviour and management of provincial governors, and obferve whatever was amifs; all which they were to lay before the præfect, who had authority to remedy fuch abufes. *Pitifc.* in voc.

MITTENDO *Manufcriptum pedis finis*, in law, a writ judicial, directed to the treafurer and chamberlains of the exchequer, to fearch for and tranfmit the foot of a fine, acknowledged before juftices in eyre, into the common-pleas, &c. Reg. Orig. 14. *Blount. Cowel.*

MITU, or MITU-PORANGU; in zoology, the name of a Brafilian bird of the pheafant-kind, according to Marggrave, and the generality of thofe who fpeak of it; but fuppofed by Mr. Ray, rather to approach to the nature of the peacock, or turkey-cock.

It is larger than the common Englifh cock, and is all over the back, wings, &c. of a fine deep black; but on the belly of a partridge-brown; and has a feries of fine gloffy black feathers on its head, which it occafionally raifes up into a fort of creft. Its beak is very beautiful, broad at the bafe and narrow at the point, and of a fine bright red. Its tail is very long, and it can at pleafure raife and expand it like the turkey. It is very eafily tamed, and loves to rooft on trees. Its flefh is very fine and delicate. See Tab. of Birds, N°. 24. *Marggrave*'s Hift. Brafil.

MIXT, in chemiftry. See the article AGGREGATE.

MIXTURE (*Cycl.*)—MIXTURA *Simplex*, *fimple* MIXTURE, in pharmacy, the name of a form of medicine ufed in the prefcriptions of fome modern phyficians. It is made by mixing ten ounces of the fpiritus theriacalis camphoratus of Bates, fix ounces of fpirit of tartar, and two ounces of fpirit of vitriol; thefe are to be fet in a glafs hermetically fealed for three weeks that they may be perfectly mixed; the dofe is a dram or thereabouts. Its virtues are, that it refifts putrefaction, promotes fweat, and is of great fervice in malignant fevers. See the article MIXTURE, *Cycl.*

MIZNEPHETH, in the Jewifh antiquities, a kind of mitre worn by the high-prieft. See the article CIDARIS.

MIZQUITL, in botany, a name ufed by fome authors for that fpecies of the Acacia, or Egyptian thorn, whofe unripe fruit affords the infpiffated juice, which is the true fuccus acaciæ of the fhops, and whofe gum, naturally flowing from the trunk and branches, is the true gum arabic. *Hernand*, p. 59. *Dale* Pharm. p. 343.

MNEME-CEPHALICUM *Balfamum*, the name of a famous compound balfam, faid to have been purchafed from a certain Englifh phyfician by Charles Duke of Burgundy, at the price of ten thoufand florins. Some who have been very lavifh in its praifes have affirmed, that it has a power of preferving in the mind the remembrance of all things that are paft; but this feems ftretching the praife of it a little too far. It is prepared in the following manner: Take of the juices of the leaves of baum, and bafil juices, of the flowers of tamarifk lillies, primrofes, rofemary, lavender, borrage, and broom, of each two ounces; of lillies of the valley, rofes, and violets, each one ounce; of cubebs, cardamoms, grains of paradife, and yellow faunders, carpobalfamum, florentine iris, faffron, favory, piony-flowers, and thyme, of each half an ounce; of liquid ftorax, ftorax-calamita, oppoponax, bdellium, galbanum, gum ivy, and labdanum, of each fix drams; roots of long birth-wort and piony, and oil of turpentine, fpikenard, coftus, juniper, bays, maftich, ben, and fpike, of each five drams. The dry ingredients are to be beaten to powder, then mixed with the reft, and a fufficient quantity of water being added the whole is to be diftilled by an alembic, and the oil carefully feparated from the water. The method of ufing it is this: The firft two months the paffages of the ears and noftrils are to be anointed with the bignefs of a pea of it every day; then for two months longer, the fame is to be repeated every third day; after this, it is to be ufed once a week, then once a fortnight, till a year is expired; and after this it is to be ufed once in two months for the fucceeding years. This is the account of Sennertus. *Sennert.* Pract. L. 1. c. 5.

MNEMONIC *Tables*. Among the artifices to affift the memory, this is one of great ufe.

Mnemonic Tables exhibit in a regular manner, what is to be remembered of the fame fubject. And altho' the fciences ought to be taught in a fcientifical manner, as much as poffible, and that every thing fhould be fo placed as to be intelligible and demonftrable from what has preceded it; yet tables ought not to be rejected, as they are helps to retain the doctrines of which the mind has had fufficient evidence[a]. In fuch tables the properties of things are to be expreffed concifely; illuftrations and demonftrations fhould be left out, as the propofition ought to have been made fufficiently clear and certain, before it is regiftred in the table. Hence the contents of fuch tables ought only to be the definitions, and the propofitions relative to the fubject. If a fubject require a long table, this may be fubdivided into fmaller; by making firft a table of the moft general heads, and referring from each

each of these heads to a separate table; by this means the order and connexion of the whole will be preserved. Such tables would produce a local and artificial memory, of great use to the retention and recollection of things. They would greatly facilitate a distinct view of the properties of their subjects, and facilitate recapitulation. Besides, as the expressions used in such tables ought to be very concise, so as just to be sufficient to excite the idea of the object to be remembered, soon after that idea has been acquired; after some time a certain obscurity will be found in perusing the tables, which will give us timely warning that our ideas begin to fade, and that they ought to be renewed. And this may be done without much trouble, if not too long delayed [b].—[a *Wolf*. Psycol. Empir. §. 200. not. p. 140. [b] Vid. Tabul. Mnem. Constrúct. & usus ap. *Wolf*. Horæ subseciv. Marburg. An. 1730. Trim. Æstiv. p. 468. seq.]

MNIUM, in natural history, the name of a genus of mosses, the characters of which are these: It has heads of two different kinds, the one sort naked and dusty, having no calyptra or other covering; the others are regular capsules, like those of the hypnum and bryum, containing a fine powder, and covered with a calyptra or hood. This diversity in the fructification distinguishes the *Mnia* from all the other mosses; but these diversly constructed heads are in some species found on the same plants; in others, on different ones of the same species, as the male and female flowers are in hemp, mercury, and many other of the larger plants. The stalks which support the membranaceous heads are long, and naked; those which support the naked heads, are in some naked, in others covered with leaves; but they are in all shorter than the others. See Tab. of Mosses, N°. 7. *Dillen*. Hist. Mosc. p. 230.

It is the general opinion, that the fine powder inclosed in the capsules of the hypnum and bryum, is of the nature of the farina fœcundans of the flowers of plants, and serves to impregnate the buds or young shoots in the alæ of the leaves, which are the female part of the fructification in this class of plants; and in this sense the membranaceous heads of the *Mnia* contain a like farina, which impregnates the globules in these naked heads, and qualifies them for acting as seeds or young plants; but all this is rather hypothesis and conjecture than observation; tho' Dillenius does suppose he has seen the germination from the globules of the dusty heads in one species of the *Mnium*. Haller says, that these dusty heads are only so many congeries of young plants when viewed with good glasses, and that therefore the *Mnium* is not properly a genus of plants, but should be referred to the bryums, to which it belongs. All this however is yet but lightly founded, and the more natural opinion seems to be that of supposing the powder in the capsules of all the mosses a true seed, not a farina. *Haller*. Helvet. p. 81. See the article Moss.

There are properly two orders of the *Mniums*. Those of the first order are erect; those of the latter procumbent, or creeping. Of the first order there are four known species: 1. The common narrow and short-leav'd *Mnium*: This is a very small moss, it grows in tufts, and produces stalks from a third of an inch to an inch in length; from these in March and April there are produced dusty or naked heads, of the size of poppy seeds. These soon ripen and shed their dust; but the membranaceous capsules arrive at their maturity more slowly, and retain their perfect state much longer: these are much less frequent than the dusty naked heads, but they usually grow upon the same stalks. 2. The transparent mother of thyme leaved *Mnium*: This seldom rises to more than an inch in height, and is very common about the bottoms of rocks and roots of trees. 3. The common large upright and forked bog *Mnium*: This is three inches high in a flourishing state, and has all its branches bifurcated: It is common in boggy places. 4. The greater bog *Mnium*, with many heads: This is less branched than the former, and has very numerous dusty heads.

Of the creeping or procumbent *Mniums*, there are only three known species: 1. The transparent trichomanes-leaved *Mnium*, with uncut leaves: This is a very elegant plant, and is common in boggy places. 2. The transparent trichomanes-like *Mnium*, with divided leaves: This is common about Hampstead and Highgate. And, 3. The lichen-leaved *Mnium*: This grows in shady places, and has the dusty heads at the extremities of the leaves.

MOAR-*Loore*, in husbandry, a term used to express a peculiar distemperature of corn, generally comprehended under the common term of a blight. In this case the earth sinks away from the roots of the corn, and leaves the plant standing in great part above ground with naked roots; these being too weak to support the stalks, the plants fall and the ears become light. This is a distemperature peculiar to corn growing on light and loose lands. *Tull*'s Horsehoeing Husbandry.

The remedy is this: Turn a shallow furrow against the rows, when they are strong enough to bear it, and the mold is fine and dry, the motion of the stalks with the wind will draw in this loose powder, and it will spread itself equally among all the plants of the row, tho' it be triple or quadruple. It is easy to see that this remedy is only practicable in the method of the horsehoeing husbandry; for in the common way of sowing, there is no means of relief in this case. And in general, the horsehoeing husbandry prevents the falling of the wheat; the stalks never drooping so absolutely in the drill'd wheat as they do in that sown in the common way.

MOARING, at sea. See the article Mooring, *Cycl.*

MOBILES, in the antient music, was an appellation given to the two intermediate chords of a tetrachord; because their variations produced the different genera and species of music [a]. They were called by the Greeks κινητοι, or κινουμενοι [b].—[a Vid. Phil. Transf. N°. 481. p. 270, 271. [b] *Wallis*'s Append. ad Ptol. Harm. p. 159.]

MOCHLICA, a term by which some authors call the violent or drastic purges.

MOEHRINGIA, in botany, the name of a genus of plants described by Linnæus; the characters of which are these: The perianthium stands expanded, and is composed of four leaves of a lanceolated figure. The flower is composed of four petals of an oval figure not indented at the ends, and smaller than the segments of the cup. The stamina are eight capillary filaments; the antheræ are simple; the germen of the pistil is globose; the styles are two, they are erect and of the length of the stamina; the stigmata are simple. The fruit is a globose capsule, composed of four valves, but having only one cell in which are several seeds, convex on one side and angular on the other. *Linnæi* Gen. Pl. p. 167.

MOCHUS, in botany, a name used by some authors for the orobus or bitter vetch. Dodonæus, among others, calls it by this name. *Ger*. Emac. Ind. 2.

MOCK-*Bird*, the name of an American bird of the merula kind, and very much approaching to the cæruleus or blauvogel. It is of the size of the common lark: Its beak is short, and strait; its tail very long; and its whole body of a very fine deep blue. *Ray*'s Ornith. p. 142.

Mock-*Lead*, in mineralogy, a name given by the English writers to a sort of fossil, called also *blende* and *galena*. It has very much the appearance of an ore of lead, being bright and glossy, of a bluish black colour, and plated; but on trial it is found to yield very little or none at all of that metal.

MODERATA *Misericordia*, in law, a writ that lies for him who is amerced in a court-baron, or other court not of record, for any transgression, beyond the quality or quantity of the offence. It is directed to the lord of the court, or his bailiff, commanding them to take a *moderate amercement* of the party. This writ is founded upon *Magna Charta*.

If a man be amerced in a court-baron, on presentment by the jury, where he did not any trespass, he shall not have this writ, unless the amercement be excessive and outrageous: And if the steward of the court, of his own head, will amerce any tenant or other person without cause, the party ought not to sue for this writ of *Moderata Misericordia* if he be distrained for that amercement; but he shall have action of trespass. New. Nat. Br. 167.

When the amercement which is set on a person is affeered by his peers, this writ of *Moderatæ Misericordiæ* doth not lie; for then it is according to the statute 10 Edw. II.

MODERATOR (*Cycl.*)—Moderator-*Ring*, in anatomy, is used by Valsalva for that ring which the muscles of the eye make round the optic nerve, at the bottom of the orbit. He alledges, that the exterior fibres of these muscles which rise from the nerve, must shorten it when they contract, and when the interior fibres act they must compress it; so that these different fibres of the muscles affect the nervous fluid here very differently.

Valsalva also describes such another ring made round the motory nerves of the eye; but acknowledges, that it is neither so remarkable nor distinct as the former. Med. Ess. Edinb. abr. Vol. 2. p. 410, 411.

MODERN-*Music*, *Musica moderna*, may be divided into two parts: First, *Antiquo-Moderna*, which is generally a serious sort of music, consisting of many parts; and which has been in use from Guido's time, to the beginning of the last century. Secondly, the *Modern* which has been used in this and the last century: It is very different from the *Antiquo-Moderna*, being brisker, lighter, gayer, and more sprightly.

MODIOLI, in natural history, a name given by some authors to the trochitæ or single joints of the rays of the petrified magellanic star-fish, which when connected in numbers together form that fossil called *entrochus*. Others also have used this word *Modiolus* to express the compound body, or entrochus itself. Tho' the general form of the trochitæ be thin and flat, yet they are sometimes found considerably thick; and tho' the entrochi or compound *Modioli* are usually so many cylinders of equal diameter in all parts, yet there are sometimes found such as are thick in the middle, and thence gradually taper to each end; some also are composed of joints, each of this form; these differ very greatly from the common kind, and instead of consisting of a number of little wheels are made up of a series of little barrels, joined, as it were, end to end.

Among large quantities of these some are found ornamented with what naturalists call the summitates or fastigia, which are long and slender pieces, and have a little button at the top.

All entrochi have a central cavity, or hollow, running thro' the whole length; and they are of different fpecies, according to authors, as this cavity differs in fize and figure. It is fometimes a mere point in the center of the ftone, and fometimes takes up a third part or more of its bulk. In fome places there are indeed found entrochi which are perfectly hollow, being only a thin cruft; of thefe, fome are perfectly fmooth and even on the furface, and others are in the common way, made up of rings, or marked with deep circular furrows. The hole in thofe *Modioli* which are thicker, is fometimes round, fometimes formed like a cinquefoil-leaf; but this laft is more rarely met with, and is called by fome of the later writers on foffils, *entrocho-afteria*, the ftarry entrochus, to diftinguifh it from the common kind. The roots, as they are called, of the entrochi have very often a configuration which leads to this; they have ufually five feet, and from each foot there paffes inwardly a little furrow to the top of the ftone. This may very well give birth to the five enlargements of the central hollow in the others, and make them *entrocho-afteriæ*. There is a fcarce fpecies found fometimes on Mendip-hills, which has fix hollows inftead of the five of the other, and thefe all terminate in angles, fo that the whole is a fexangular hollow, whereas the cinquefoil inlets are ufually round as the leaf whofe name they bear, thu' fome few of them have fharp angles. Phil. Tranf. N°. 129.

The joints and fockets by which the entrochi are joined together are very various, for as feveral rays fhooting from a center muft of neceffity have confiderable wideneffes between them, as they pafs toward the circumference, according to the bignefs; fo to fill up thofe wide fpaces in fome, between two rays there iffues from the center a third ray, which paffes as the others to the circumference of the ftone. Some have their rays gently widening from the center all the way to the circumference: In fome, between two forks, made by a ray that parted fingle from the center but divides afterwards, there rifes alfo a little ray which runs to the circumference: And fome others are ramofe, having a trunk rifing from the center, with three, four, or five branches, running to the circumference: Some alfo are fmooth half way of the ftone from the center, and have a circle of fmall rays near the circumference; and fome are perfectly fmooth, and have no rays at all. Thefe are ufually very thick, and are joined together in the entrochus after this manner: One trochite, or fimple *modiolus*, a little within the outer circle, in the upper and lower parts, where the rays ufe to be, has round inlets or fockets confiderably deep, fo that only a thin tympanum hinders the trochite from being hollow at this width all through; and in the middle of this tympanum there is a hole as in the other trochitæ, which is fometimes round, and fometimes of a pentangular figure. The trochites that anfwer this, have fmooth joints on both fides, without any fkrew-like ridges entering into thefe fockets, thofe joints being hollow alfo; and fo other trochitæ with fockets come on again upon thefe; and thus the entrochus is made up. Some of thefe *Modioli* have both fockets and rays, and fome have a focket alone on one fide, and rays without a focket on the other. Finally, fome are perfectly fmooth, only that a fmall ridge runs round them, a little within the outer circle, which enters into a fmall furrow anfwering to it; and fome are fmooth and joined only *per harmoniam*. Some of the trochitæ hold of an equal thicknefs from the center to the circumference, and others are confiderably thick at the circumference, and thence grow gradually thinner to the central cavity, at the verge of which, all round, they make a fort of edge. Thefe have concavities on both fides, to which convexities in the adjoining trochitæ anfwer: Some hold of an equal thicknefs half way from the circumference toward the center of the ftone, but they then grow thin, and continue fo to the very verge of the cavity.

Befide the generality of thefe trochitæ which are round, there are others found which are of an oval figure, fome rounded at the ends, and fome pointed; thefe have their central cavity as well as the others, and fome have it very fmall, others very large. In thefe it is always oblong, according to the fhape of the ftone, not round, as in the round ones. Thefe ufually are not joined in the entrochus by means of rays, but have a ridge running all along the verge in one, which is received into a furrow in the other. Some of thefe joints are fhaped with a double oval, the oval of the upper part of them ftanding contrary to the oval in the lower: in others, the ovals do not ftand fo entirely oppofite one to another, but only the oval in the upper part feems a little wrefted from the direct line of the oval of the lower part, fo that they ftand bendwife to each other, and make up a figure like a St. Andrew's crofs. There are entrochi made up in this manner, and it is in general obferved, that moft of the oval entrochi grow crooked and twifting. Thefe oval ones are found lefs frequently in the entrochus ftate, than in the fingle trochites; but they are fometimes met with, and are liable to all the accidents in figure and furface of the common round ones. The obfervations of the manner of joining of the feveral trochitæ into the entrochus, and of the rays and fpaces, with the manner of filling up the latter, and the various divarications of the former, are a very pleafing obfervation; but it is neceffary, in many cafes, to have recourfe to the affiftance of glaffes for the perfectly underftanding them, the naked eye lofing a great part of the ftructure.

MODIRA *Kaniram*, in botany, a name given by fome authors to the tree, whofe wood is the *lignum colubrinum*, or fnake-wood of the fhops. Hort. Malab. vol. 8. p. 47.

MODULUS *of the logarithmic Syftem*. See the article LOGARITHM.

MOFFAT *Waters*, mineral waters of confiderable efficacy at *Moffat*, in the county of Annandale. They arife from two fprings on the declivity of a hill, which yield about 1360 gallons of water daily. Thefe waters have a fulphureous tafte, and fmell of the wafhings of a gun-barrel; their colour is milky or bluifh. The feafon for ufing them is between the middle of April and the end of September; but they may be drank all winter, and if the rains be moderate, the ftrength of the water is not found to be impaired. The water of the upper fpring being too foul for drinking, is made ufe of for bathing, and is, for this purpofe, made fomewhat warmer than tepid. The quantities of water ufually drank are pretty large, exceeding fometimes a gallon. It is ufual to join purgatives, and that in great dofes, frequently repeated with the ufe of the waters; but this is thought unjuftifiable by fome [a]. The water is alterant and diuretic. Its purging is owing to the large quantities drank, or to fome fingularity in the conftitution, as a weak ftate of the ftomach and inteftines. Few medicines are faid to be fuperior to thefe waters in diforders of the ftomach and bowels. It has alfo proved ufeful in nephritic, nervous, and hyfteric colics, melancholy, barrennefs, female weakneffes and diforders, as alfo in old gleets, either natural, or caufed by venereal diforders. In rheumatic and fcorbutic complaints it is advantageous, and in cutaneous eruptions. It is faid feldom to fail in fcrophulous diforders [b]. This water gives no marks of a chalybeat nature with galls, nor of acidity with tincture of rofes, or fyrup of violets, neither does it produce any effervefcence with oil of tartar *per deliquium*, or fpirit of fal ammoniac. It feems to contain a fubtil volatile fulphur, but in fmall quantity, fince it foon lofes its remarkable fmell and tafte, when expofed to the air, and that acid liquors can neither feparate nor precipitate it. Upon evaporation there is found a dirty falt mixed with earth. This falt feems not to be nitre, nor fal ammoniac, but common falt, and by a flow evaporation of a folution of fea falt, cryftals not unlike thofe of the falt of *Moffat* water have been obtained [c].—[[a] Medic. Eff. abr. vol. 1. p. 99. [b] Ibid. p. 101. [c] Ibid. p. 103. feq. where other experiments on thefe waters may be feen.]

MOGORIN, in botany, a name given by the Portuguefe to an Indian or Chinefe flower, growing on a fmall fhrub. It is of a wonderful white colour, and not unlike the *gin-feng*, only that it abounds more with leaves, and fmells much fweeter; one fingle flower filling a whole houfe with its odoriferous effluvia. On this account the Chinefe put a high value upon it, and carefully defend the fhrub it grows on from the inclemency of the winter, by covering it with vafes provided on purpofe. *Hofm.* Lex. in voc.

MOHAUKS *Corn*, in botany, a name given by the Indians to a peculiar fort of the maiz, or Indian corn. It is moft frequent in the more northerly parts of America. The general time of fowing the maiz in Virginia and other places, is in the end of April; but this *Mohauk* kind need not be fown before June, and yet will come well to maturity before the winter. The ftalks of this kind are fhorter than thofe of the common fort. The ears alfo are fhorter, and grow nearer the ground, and the corn is generally of various colours. Phil. Tranf. N°. 142.

MOIRE, in conchyliology, the mohair fhell, a name given by the French virtuofi to a peculiar fpecies of voluta, which feems of a clofely and finely reticulated texture, and refembles on the furface a piece of mohair, or a very clofe filk-worms web. See the article VOLUTA.

MOISTURE (*Cycl.*)—The *Moifture* of the air has confiderable effects on the human body. For the quantity and quality of the food, and the proportion of the meat to the drink, being given, the weight of a human body is lefs, and confequently its difcharges greater in dry weather than in wet weather; which may be thus accounted for: The *Moifture* of the air moiftens the fibres of the fkin, and leffens perfpiration, by leffening their vibratory motion. When perfpiration is thus leffened by the *Moifture* of the air, urine, indeed, is by degrees increafed, but not equally. See Dr. *Bryan Robinfon*'s Diff. on the Food and Difcharges of human Bodies, p. 68. feq.

Hence we learn, that to keep a body of the fame weight in wet weather as in dry, either the quantity of food muft be leffened, or the proportion of the meat to the drink increafed; and both thefe may be done by leffening the drink, without making any change in the meat.

MOLA, (*Cycl.*) a mole, or falfe conception, in medicine, is a membranaceous and fibrous concretion in the womb, containing ufually a large quantity of coagulated or thick blood. This is fometimes produced alone in the uterus, fometimes at the fame time with a regular fœtus. There are many origins to be affigned to thefe concretions, but the moft ufual feems to be the

the leaving behind of part of the fecundines after abortion. In young people thefe are lefs dangerous, and feldom remain in the womb more than a year, but in older perfons they fometimes remain many years, and at length often occafion the death of the perfon. When they are produced in the womb at the fame time with a regular fœtus, they ufually deprive it of part of its nutriment, and occafion falfe pains, and many irregular complaints, during the time of geftation; but thefe ufually are attended with fewer accidents at the time of delivery than when the fame fubftances are produced alone in the womb. The German writers of wonders give accounts of thefe concretions being living animals, armed with claws and beaks, or wide mouths, and deftroying the fœtus when they are in the womb at the fame time with one; but thefe are idle reports, and are to be looked upon in the fame light with the hiftories of Sooterkins. *Junk.* Confp. Med. p. 721.

The figns of a *Mole* in the uterus are very dubious, and during the firft months of geftation, it is fcarce poffible to diftinguifh it from a genuine fœtus; but after this, if the fymptoms of pregnancy go on, and there is no motion perceived at a time when the fœtus ought to ftir, it is fhrewdly to be fufpected that this is the cafe; and this becomes the more evident, if after this time there come on irregular and uncertain difcharges of blood from the uterus, at different times; in this cafe there is alfo ufually fo great a flaccidity in the ligaments of the uterus, that it does not retain its place in the body; but when the perfon turns in bed, is plainly felt falling like a dead weight from one fide of the abdomen to the other. It is alfo obferved, that in thefe cafes, tho' the belly fwells as much as when there is a genuine fœtus, yet it is not fo regularly rounded before, but is flatter at the middle, and more turgid toward the fides, fo that the burthen feems carried on one or the other fide, or partly in both, while the middle remains empty. There is always in this cafe alfo a fenfation of a weight on the lower part of the abdomen, greater by much than in the cafe of their being really a child there. At the regular time of delivery, the cafe becomes much plainer than before; for there then come on either no pains at all, or thofe which come are flight and inconfiderable, very irregular in their periods and returns, and by no means fufficient for the exclufion of a fœtus. When the *Mole* happens at the fame time with the fœtus, it is feldom to be difcovered till the time of delivery, or if it be found out fooner, there can be nothing done till both that and the fœtus are excluded; after this the womb is to be very carefully cleanfed, as in abortions. At other times, when the cafe is obvious, that there is a *Mole* without any fœtus, the common forcing medicines are to be given for feveral days every month, about the time of the periodic returns of the menfes; and if thefe do not bring it away, recourfe is to be had to the hand of the midwife. *Junker's* Confp. Med. p. 723.

We find a very fingular inftance in Kerkring, of a *Mole*, in which a child was enclofed. The whole was declared a falfe conception, and might have been facrificed as fuch, had not fome perfon prefent obferved fomething ftir within it, and, on the opening it, taken out the living child. *Kerkring*, Specil. Anat.

Mola, in zoology, the name of a fifh commonly called in Englifh, the *fun fifh*. It is of a very fingular figure. Its body is broad and fhort, and its hinder extremity is terminated by a circular fin, which ferves it for a tail; fo that it looks like the head of a large fifh fever'd from its body; it is frequently of two foot in length, and fometimes very much exceeds that fize, growing even to two hundred weight. It has no fcales, but is cover'd with a hard, harfh, and rough fkin. Its back is black, and its belly white; the fides are of a middle colour between both. Its back and belly both terminate in a narrow edge. Its mouth is very fmall for the fize of the fifh, and, when open, is round. Its jaws are hard, and edged like a knife within; externally they are rough, as if befet with feveral rows of fmall teeth. The head does not at all project from the reft of the body. The eyes are very fmall. It has only one pair of fins, which are fituated near the gills, which are only two elliptic holes covered with their proper membranes. Its flefh is very foft, and its bones are all grifly and tender. The fkin fticks very firmly to the flefh, and is not eafily taken off. It is caught in the Mediterranean, and fometimes in the Britifh feas. See Tab. of Fifhes, N°. 27. *Willughby's* Hift. Pifc. p. 151.

MOLAGO *Codi*, in botany, a name by which fome authors have called the plant which produces the common black pepper. Hort. Mal. vol. 8. p. 23.

MOLANGA, in botany, a name given by fome authors to the plant which produces the common black pepper. *Pifo.* Mant. Arom. p. 492.

MOLARES *Dentes* (*Cycl.*)— Thefe are twenty in number, five being placed on each fide of both jaws, immediately after the canini. The two firft in each row are fmall, the two next larger, as is alfo the laft, which appears very late, and is often wholly wanting. The *Molares* have been, according to this difference in their fize, diftinguifhed into fmall grinders, large grinders, and *dentes fapientiæ*, or the teeth of wifdom, fo called, becaufe they feldom appear till people are arrived at years of difcretion.

The bodies of the *Molares* in general are very thick, fhort, and irregularly cylindrical, or rather with four fides, a little rounded, and terminated by a broad end, more or lefs filled with obtufe points, cut, in fome meafure, like fo many diamonds. The name of *crown* is alfo frequently given to the bodies of thefe teeth, from fome fort of refemblance they are fuppofed to have to it. In the two fmall *Molares*, the crown is lefs than in the others, and often not fo large as the bodies of the canini: they have ufually but two points. In the two large *Molares*, the crown has a much greater extent, and the points are three, four, or five in number. The fifth grinder, or *dens fapientiæ*, has ufually a crown much like the two former, but commonly more rounded, and with fewer points. The roots of the *Molares* are long, and more or lefs flat; in fome fingle, in others two, three, or four, and fometimes, but rarely, five in number; fometimes all thefe roots are diftinct, fometimes they are wholly united, and fometimes they are united only in part; they are generally ftrait, and at a greater diftance from one another at their extremities than at the crown of the tooth. The roots of the fmall grinders appear often fingle, without being fo in reality; for in examining them narrowly, they are found to have two roots united, or foldered together; and fometimes all the diftinction that appears, is in their having two feparate points. The great *Molares* have commonly feveral roots, the firft three, and the fecond four; or fometimes, the firft four, and the fecond five; but thefe numbers are variable. The roots are fometimes all perfectly diftinct, and fometimes they are partly diftinct, and partly united in the fame tooth in different degrees; and in fome fubjects, one or more of their points are bent outward, inward, or in other directions; and it is not always that more roots are met with in the upper teeth than in the lower. The fifth grinder has often but one root, and that is fometimes very fhort, and fometimes remarkably long. It is common to meet with this tooth in grown perfons almoft wholly hid in its focket, and it has, in thefe cafes, but a very fmall opening for it to appear at. In all the *Molares*, near the collar, the roots, be they ever fo many, meet and unite into one body. *Winflow's* Anatomy, p. 43.

Molares, in the natural hiftory of the antients, the name for the compound mineral bodies we now call *pyritæ* and *marcafites*. See the articles Pyritæ, and Marcasite.

MOLDAVICA, in botany, the name of a genus of plants, the characters of which are thefe: The flower confifts of one leaf, and is of the labiated kind. The upper lip is fomewhat arched, bifid at the extremity, and turned upwards; the lower one is alfo bifid, and both of them terminate in marginated edges, refembling the mouth of fome animal. The cup is tubulated, and ufually divided into two unequal lips. The piftil arifes from this, and is fixed in the manner of a nail to the hinder part of the flower, and furrounded by four embryos, which ripen into oblong feeds, and are contained in the cup of the flower.

The fpecies of *Moldavica*, enumerated by Mr. Tournefort, are thefe: 1. The blue-flowered betony-leaved *Moldavica*. 2. The white-flowered betony-leaved *Moldavica*. 3. The betony-leaved *Moldavica*, with flefh-coloured flowers: And 4. The ftrong-fcented trefoil *Moldavica* of America, called by fome, the balm of Gilead plant, from its fmell. *Tourn.* Inft. p. 184.

MOLE, *Talpa*, in zoology. See the article Talpa.

Mole, *Mola*, in medicine. See the article Mola.

Mole-*Hills*. Thefe little hillocks of earth are a very great prejudice to the pafture lands, not only in wafting fo much of the land as they cover, but in hindering the fcythe in mowing. In the weft of England they ufe a peculiar inftrument for the breaking up of thefe; it is a flat board, very thick, and of about eight inches in diameter, into which there is faftened a perpendicular handle of three or four foot long. It has four broad and fharp iron teeth at the front, which readily cut through the hill, and fpread the earth it confifts of; and behind there is a large knob, proper for breaking the clods with, if there are any. Some ufe a fpade, or other common inftrument, in the place of this, but not fo well. There is, however, a much better inftrument even than this, for deftroying thefe hills, where they are in very great numbers. This is a kind of horfe machine; it has a fharp iron about three foot over, and with a ftrong back. It is about four or five inches broad, and has two long handles for a horfe to be harneffed to, and a crofs bar of iron to ftrengthen it at the bottom of the handles, reaching from the one handle to the other. The middle of this crofs bar is furnifhed with one, two, or more, fharp pieces of iron, like fmall plow-fhares, to cut the *Mole-hills* into two, three, or more parts. The iron behind is of a femicircular figure. A fingle horfe is harnefs'd to this machine, and a boy muft be employed to drive it, and a man to hold and guide it; the fharp irons or fhares are the firft things that meet the hill, they run through it, break its texture, and cut it into feveral parts, and the circular iron following immediately behind them, cuts up the whole by the roots, and leaves the land level. This inftrument will deftroy as many *Mole-hills* in one day as a common labourer can in eight, and would be of very great advantage to the kingdom, if brought into general ufe. *Mortimer's* Hufbandry, p. 331.

It is to be obferved, that this leaving a naked fpace in the place of every hill, it will be neceffary to go over the land, and fow them with hay-feed, otherwife thefe fpots will want the

the produce of grafs the firft years. The farmers in fome parts of England are not willing to deftroy the *Mole-hills*, but let them ftand from year to year, fuppofing that they get fome ground by them; but the advantage by this means is fo little that it does not ballance the unfightlinefs and damage to the mowing.

MOLE-*Cricket*. See the article GRYLLOTALPA.

MOLES-*Carnea*, in anatomy, a name given by Vefalius, and others, to a mufcle, called by Winflow, Albinus, and others, the *complexus*. Spigelius calls it the *Carnea Moles Trigemino adjuncta*. See the article COMPLEXUS.

MOLES *Carnea Labia formans*, in anatomy, a name given by Fallopius to the mufcle called by Albinus *orbicularis oris*, and by Cowper *conftrictor labiorum*.

MOLLE, in botany, the name of a genus of plants: The characters of which are thefe: The flower is of the rofaceous kind, or compofed of a number of petals arranged in a circular form; the piftil finally becomes a fruit refembling a grain of pepper. *Tourn.* Inft. p. 661.

There is only one known fpecies of this genus, which is the *Molle* of Clufius, called by Cafpar Bauhine the Peruvian lentifk.

MOLLE, in ichthyography the name of a fmall fpecies of whiting, common in the Mediterranean, and in the markets of Rome, Venice, &c. and called by authors the *Afellus omnium minimus*, and the *merlangus*. It is the fmalleft of all the afellus kind, feldom exceeding four inches in length; it has a beard like the cod, hanging from the angle of its lower jaw; and has on each fide nine fpots on its nofe and gills; the back is of a pale brown, the belly white, and it has extremely fmall and foft fcales. The flefh is very delicate. *Ray*'s Ichthyogr. p. 171.

MOLLE, in the antient mufic, a name given to a fpecies of the diatonic; and alfo to a fpecies of the chromatic. See the articles DIATONIC, and CHROMATIC.

The Greeks called it μαλακον, and ufed the term in oppofition to *intenfum*, συντονον. As the latter was formed by increafing the tenfion of the chord, and thereby making it approach nearer to the higheft extreme of the tetrachord, fo the *Molle* was formed by remiffion or relaxation. Hence the divifion of the diatonic into *Molle*, μαλακον, and *intenfum*, συντονον. *Ariftoxenus*, p. 50, 51. edit. Meibom. See the articles DIATONIC, and GENUS.

MOLMAN, in our old writers, a man fubject to do fervice. It is applied to the fervants in a monaftery. *Spelm.* Gloff. *Blount.*

MOLOCH, an effected term ufed by fome chemical writers, to exprefs a leaden pot, through which mercury is made to pafs in the fire.

MOLOCH, in antiquity, the name of the Phœnician god. See the article DÆMON, *Cycl.*

MOLOCHITES, in natural hiftory. See the article MALACHITES.

MOLOPS, a word ufed by fome medical writers, to exprefs the purple fpots which appear upon the fkin in malignant fevers.

MOLOSSES (*Cycl.*)—*Artificial* MOLOSSES. There has been found a method of making *Moloffes* from apples, without the addition of fugar. The apple that fucceeds beft in this operation is a fummer-fweeting of a middle fize, pleafant to the tafte, and fo full of juice, that feven bufhels will yield a barrel of cyder.

The manner of making it is this: The apples are to be ground and preffed, then the juice is to be boiled in a large copper, till three quarters of it be evaporated: This will be done with a moderate fire in about fix hours, with the quantity of juice above-mentioned; by this time it will be of the confiftence and tafte as well as of the colour of *Moloffes*.

This new *Moloffes* ferves to all the purpofes of the common kind, and is of great ufe in preferving cyder. Two quarts of it put into a barrel of racked cyder, will preferve it, and give it an agreeable colour.

The invention of this kind of *Moloffes* was owing to Mr. Chandler of Woodftock in New-England, who living at a diftance from the fea, and where the common *Moloffes* was very dear and fcarce, provided this for the fupply of his own family, and foon made the practice general among the people of the neighbourhood. It is to be obferved, that this fort of apple the fweeting, is of great ufe in making cyder, one of the very beft kinds we know being made of it. The people in New-England alfo feed their hogs with the fallings of their orchards of thefe apples; and the confequence of this is, that their pork is the fineft in the world. Phil. Tranf. N°. 374. p. 230.

MOLOSSES *Spirit*; a very clean and pure fpirit, much ufed in England, and made from *Moloffes* or common treacle diffolved in water, and fermented in the fame manner as malt for the common malt-fpirit. If fome particular art is not ufed in the making this, it will not prove fo vinous as the malt-fpirit, but more flat and lefs pungent and acid, tho' otherwife much cleaner tafted, as its effential oil is of a lefs naufeous flavour. Whence if good frefh wine leys, abounding in tartar, be duly fermented in the folution made thin for that purpofe, the fpirit will by that means become much more vinous and brifk, and approach more to the nature of the foreign fpirits.

After the firft diftilling of *Moloffes* fpirits from the wafh into low wines; it is to be rectified, and in the fucceeding rectifications proper additions are to be made. Alkaline falts, fo common in the rectifying the malt fpirits, muft be avoided in this cafe, as not at all fuiting this fpirit, and the neutral ones only muft be ufed, fuch as fandiver, common decrepitated falt, fal enixum Paracelfi, and the like; but upon the whole nothing fo confiderable is to be expected from thefe falts, as from a careful rectification in balneo mariæ, without any other admixture; by this alone repeated two or three times with frefh water each time, the fpirit will at once be made fit for the niceft ufes.

Where the *Moloffes* fpirit is brought to the common proof ftrength, if it be found not to have enough of the vinofity in it, it will be very proper to add to it fome good fpiritus nitri dulcis; and if the fpirit be clean worked, it may by this addition alone be made to pafs on ordinary judgments for French brandy.

When newly diftilled, this fpirit like all others is colourlefs, and limpid as water; but our diftillers always give it the fame fort of yellow tinge, which the foreign fpirits are found to obtain from the cafks they are fent over in. They have many ways of giving this colour extempore; but the two moft in ufe are, either by an extract of oak-wood, or by burnt fugar. *Moloffes* fpirit coming dearer than that of malt, it is frequently met with bafely adulterated with a mixture of that fpirit, and indeed feldom is to be bought without fome dafh of it. Many have a way of mixing malt in the fermenting liquor, by this the yield of the whole is greatly increafed, and the maker may affure the buyer that the fpirit is pure as it ran from the worm.

England is the principal place where this fpirit is made at this time; it was at one time prepared in great quantities in France, efpecially in the river Loire; but it is now forbid there, under a fevere penalty. In Holland alfo they have it not, on account of the high duty laid upon treacle in favour of their own fugar-bakers.

We meet with very little of *Moloffes* fpirit reduced to the ftrength of alcohol or fpirit of wine, tho', when rectified to this ftate in a proper manner, it is very little inferior to the real alcohol of wine, the name of which is fo well known among us, tho' the thing itfelf is perhaps never feen here. All that we call fpirit of wine being no other than malt fpirit reduced to an imperfect alcohol, or a fpirit almoft totally inflammable. Great quantities of *Moloffes* fpirit are ufed in the adulterating of brandy, rum, and arrack; and great quantities are ufed alone in the making cherry-brandy and other drams by infufion, in all which many prefer it even to the foreign fpirits.

In moft of the nice cafes in our compound diftillery the *Moloffes* fpirit fupplys the place of a pure and clean malt fpirit, which we have not yet the way of producing in the large way to advantage. Our cinnamon, citron, and other fine cordial-waters, are made with it; for the malt fpirit would give thefe a very difagreeable flavour.

There is alfo another ufe to which this fpirit ferves extremely well, and which even a foreign fpirit that has any remarkable flavour will not do fo well in; this is the making the extemporaneous wine, which fome people are fo fond of. See the article *Extemporaneous* WINE.

It gives a yellow ftain to the hands, or other fubftances dipped into it; and may therefore be of ufe in dying. It is poffible alfo, that the vinegar-makers may find ufe for it in their way; but the moft advantageous of all its ufes, is to the diftiller himfelf, a quantity of it added to new treacle intended for fermentation will be of great ufe in the procefs, and increafe very confiderably the quantity of fpirit; but the proportion in regard to the new matter muft not be too great. *Shaw*'s Effay on Diftillery.

MOLTEN-*Greafe*, in the manege, is a fermentation or ebullition of pituitous and impure humours, which precipitate and difembogue into the guts, and oftentimes kill a horfe. This difeafe does not commonly feize upon any but very fat horfes, when over-rid in very hot weather.

MOLVA, in zoology, a name by which fome authors have called the common cod-fifh, called the *morhua*, and *afellus major* by other writers. *Gefner* de Pifc. p. 102. See the article COD-*Fifh*.

MOLUCCA, in botany, the name of a genus of plants; the characters of which are thefe: The flower confifts of one leaf, and is of the labiated kind; the upper lip is hollowed in the manner of a fpoon, and the lower is divided into three fegments. The piftil arifes from the cup, and is fixed in the manner of a nail to the hinder part of the flower, and furrounded by four embryos, which afterwards become four angular feeds, ripening in a bell-fafhioned open capfule, which was before the cup of the flower. See Tab. 1. of Botany, Claff. 4.

The fpecies of *Molucca*, enumerated by Mr. Tournefort, are thefe: 1. The fmooth *Molucca*. 2. The prickly *Molucca*. And, 3. The fhrubby *Molucca* of Sicily, called by fome authors fhrubby balm. *Tourn.* Inft. p. 187.

Thefe plants are otherwife denominated *Anacardiums*. See the article ANACARDIUM.

MOLUCCA-*Beans*, a name given by Sir Robert Sibbald, in his prodromus; and by Mr. Wallace, in his defcription of the Orkney-iflands, to a fort of fruit frequently caft on fhore in the north-weft iflands of Scotland; efpecially on the coafts moft expofed to the waves of the great ocean.

They are called by fome Orkney-beans, and are not the produce of that ifland, or indeed of any other part of Europe, but of America.

Sir Hans Sloane procured four fpecies of them little injured by the fea, and found on examination that three of them were the common produce of the ifland of Jamaica; where he had himfelf gathered them, and defcribed them in his catalogue and hiftory.

The firft fort was a kind of kidney-bean, and the plant which produces it is defcribed by Sir Hans under the name of the great perennial kidney-bean with a great crooked lobe. It is alfo figured in the Hortus Malabaricus, by the name of *Perim Kakuvalli*, and Sir Robert Sibbald alfo calls it *Nux Indica ex qua Pyxides pro pulvere fternutatorio parant*. This is a native of the Eaft and Weft-Indies, and is fometimes found thrown on fhore in the county of Kerry in Ireland; and in fome other places.

A fecond kind of fruit thrown on fhore in the Orkneys, is a very common fruit in Jamaica, known there by the name of the horfe-eye bean; it has this name from its refembling the eye of fome large animal by reafon of a hilus or welt which furrounds it. This is defcribed by many authors, and among the reft by Sir Hans Sloane, in his catalogue of the Jamaica plants; and is found in many other of the hotter parts, both of the Eaft and Weft-Indies.

A third kind of fruit found on thefe fhores, is that called by the people of Jamaica the afh-coloured nickar-nut; it has this name from its colour, and from its being perfectly round and of the fhape of a nickar or marble, fuch as boys play with: This alfo is common to the Eaft and Weft-Indies.

A fourth kind is alfo a Jamaica fruit, with the hiftory of which we are not yet well acquainted; no body has feen it growing, but the fruit itfelf is preferved in many of the collections of the curious, and has been figured and defcribed by Clufius, and others, under the name of a round exotic fruit ridged with four rifing nerves.

Thefe are the principal kinds of fruit thus toffed on fhore with us; but how the products of Jamaica, or other parts of America, fhould be brought to the fhores of Scotland and Ireland, feems not eafy to determine on any certain foundation. It is eafy to conceive, that when they grow by the fides of rivers they may fall off from the trees into them, and be thence conveyed into the fea. It is likewife eafy to fee, that when they are thus floating on the furface of the fea they may be carried about by the winds and currents, and be carried a great way; but their journey this way muft naturally be ftopped by the main continent of America, and they muft be forced through the gulf of Florida, or the canal of Bahama, going thence conftantly eaft, and into the North-American fea. This is eafily conceived by a fimilar fact which happens every day: which is, that a kind of fea-lentil, called *fargaffo*, which grows very plentifully on the rocks about Jamaica, is wafhed off from thence and carried by the winds and currents, which for the moft part go impetuoufly the fame way, toward the coaft of Florida, and thence into the North-American ocean; and are there found floating on the furface. Thus far it is eafy to trace our fruits from their native foil; but how after this they fhould make the reft of their voyage is a great myftery, and not to be accounted for by us, unlefs we fuppofe, that as fhips when they go fouth expect a trade eafterly wind, and when they come north expect and generally find a wefterly wind, for at leaft two parts in three of the year; fo we are to fuppofe thefe fruits being brought north by the current from the gulf of Florida, are put into thefe wefterly winds way, and by them conveyed to the coafts of Scotland and Ireland. Philof. Tranf. N°. 222. p. 300.

By the fame means that thefe beans came to Scotland, it is reafonable to believe that the fame winds and currents brought from America thofe feveral things towards the Azores and Porto Santo, which are recorded by Ferdinand Columbus, in the life of his father; which gave this bold adventurer the firft notions of there being fuch a place as America. The things he mentions as wafhed afhore in this manner, were a piece of wood very ingenioufly wrought, but evidently without the help of iron tools. This was taken up by a Portuguefe pilot, four hundred and fifty leagues from fhore, off cape St. Vincent, after a weft wind, which had blown violently for many days: After this fuch another piece of wood was taken up on the fhores of Porto Santo, after fuch another long and violent weft wind. After this large canes, vaftly fuperior to any of the growth of the then known parts of the world, were found thrown on the fame fhores, and the fruits of pines which did not grow in any known part of the world; and finally the bodies of two men appearing to be of a different nation from any of the known people, and two of their canoes, were driven on fhore on the ifland Flores, one of Azores. All thefe things having been found only after ftrong and continued weft winds, it appeared very evident, that there muft be land fomewhere to the weft, where fruits and men were to be found; and that thefe men had no knowledge of our arts, by their want of iron. It was eafy to fee from this how ufeful we might be to them, if they could furnifh us with any thing of value. And on this plan was founded the greateft difcovery of the modern times.

MOLY. The name of this plant is rendered famous by Homer, and has been on this occafion much enquired into as to its true fenfe, by the botanifts of almoft all times. The old interpreters of Homer all explain this word by the wild rue; and the only reafon for this is, that at fome time, probably long after the days of Homer, the people of Cappadocia called the wild rue *Moly*. But this plant is wholly different from the *Moly* of Homer, which Theophraftus affirms grew in his time in Arcadia, in great plenty, and had a round bulbous root like an onion, and long and graffy leaves like the fquill.

The authority of this author, who wrote profeffedly on the fubject of plants, and wrote fo early, is fufficient to explode the abfurd opinion of the *Moly* of Homer, being wild rue; but tho' the commentators are thus eafily fet afide, there is yet another author who will lead into no lefs errors. This is Pliny, who has blended together the accounts of all the writers before him on this fubject; and as they have contradicted one another, he has preferved all their contradictions. After telling us the fabulous ftory of its being found out by the god Mercury, and being good againft witchcraft and the like, he tranflates the words of Theophraftus, that it grows about Phineas and Cyllene, in Arcadia; and has a round and black root of the fhape of an onion, and leaves like the fquill. To this Theophraftus has added, that it is not however difficult to be dug up, as Homer feems to think; but Pliny, to make Theophraftus and Homer agree at any rate, leaves out the word *not* in his tranflation, and fays, that it is very difficult to be dug up. *Pliny*, L. 25. c. 4.

The phyficians of Italy, in the time of Pliny, were fond of believing that they had the true *Moly* of Homer growing in the Campania of Rome; and Pliny feems to have been alfo wholly convinced of it; and mentions as a reafon of his conviction, that they had brought to him a root of *Moly*, which was dug up with prodigious difficulty from among rocks and ftones, and which, when he faw it, meafured thirty foot long, yet was not compleat, but broken off at the end; fo that it might poffibly have been much longer. The author's fkill in botany appears to have been very little, that could make him believe, becaufe of the fingle obfervation of the difficulty of getting it up, that this was the true *Moly* which he had juft before defcribed from Theophraftus, as having a round root like an onion.

It is probable that this was the root of the faint-foin or lucerne, both thefe plants growing wild in Italy, and both having roots of a prodigious length, probably not lefs than that here mentioned by Pliny; but that he could fuppofe thefe roots to be of the bulbous kind, fhews an ignorance that but ill agrees with the veneration fome people have for this author.

This plant had nothing in common with the *Moly* of Homer and that of Theophraftus, excepting the difficulty of getting it up, which Theophraftus denys to be a truth; and in which probably Homer was mifinformed, as no bulbous root can be very difficult to get up; but Pliny, that the Roman root might agree with the true *Moly*, firft compels Theophraftus againft the letter of his own account, to fay *Moly* was hard to be dug up, and then makes this a reafon for a plant's being the true *Moly*, which does not appear to have had any one character in common with it. Nature is uniform in her productions, and tho' a bulbous plant fuch as the *Moly* of Theophraftus, would naturally have graffy leaves, as all bulbous plants have; yet this long-rooted plant, defcribed by Pliny, in the common courfe of nature could not have fuch, but probably had either pennated or trifoliate leaves.

Pliny adds, that the Greek authors have made the flowers of the *Moly* yellow, whereas Homer fays that they were white; but it does not appear that this is a juft accufation, for neither any of the Greek writers extant at this time, nor any of the fragments of others which we find recorded, exprefs any fuch thing: On the contrary, the whitenefs of the flower feems to have been always looked upon as one of the great and effential characters of the *Moly*; and the wild rue feems to have been fuppofed the *Moly* of Homer, only becaufe it has white flowers, and roots black on the outfide. The error of Pliny in fuppofing the Greeks to have called the flowers of the *Moly* yellow, feems to have arifen from a Greek writer having faid, that the flowers are like thofe of the leucoium, but white as milk. He has probably taken this fentence, but without the laft word, and then accufed the author of faying they were like the leucoium flowers in colour, when he only fays they are fo in fhape.

The author of the Priapeian verfes feems to follow this, and fays, that yellow or gold-coloured flowers arife from the *Moly*; but this is by no means confonant to Homer's account, who fays they are white like milk. And fo fay all that have written after him.

On the whole, the *Moly* of Homer feems to have been a fpecies of allium or garlic. See the article GARLICK, fp. 32.

MOLYBDÆNA, *Leadwort*, in botany, a name given by ſome authors to the great toothwort, or dentillaria of Rondeletius. *Ger.* Emac. Ind. 2. See the article PLUMBAGO.

MOLYBDÆNA is alſo a mineral ſubſtance, called *black lead.* See the article BLACK *Lead.*

MOLYBDIA, in natural hiſtory, the name of a genus of cryſtals. The word is derived from the Greek Μόλυβδος, lead; and expreſſes cryſtals altered in their figure by particles of that metal. The cryſtals of this genus are of a cubic form, or compoſed of ſix ſides, at right angles, like a die.

Of this genus there are three known ſpecies. 1. A colourleſs one, compoſed of extremely fine cruſts. This is found in many parts, both of this and other kingdoms, where there are lead mines; and tho' naturally colourleſs, is ſometimes tinged with a red, green, or blue. 2. A dull one with thicker cruſts, ſometimes whitiſh, and ſometimes coloured to a yellowiſh or other hue. This is found in the lead mines of Yorkſhire, and ſome other places. And 3. A dull bluiſh white one, with very thick cruſts. This is very frequent in the lead mines in Derbyſhire, and is generally found in large cluſters. *Hill's* Hiſt. of Foſſ. p. 193.

MOLYBDOMANTIA, Μολυβδομαντεια, in antiquity, a ſpecies of divination, by obſerving the motions, figures, &c. of melted lead. *Potter's* Archæol. Græc. lib. 2. c. 18.

MOLYZA, μώλυζα, a word uſed by the Greek phyſicians to expreſs a head of garlick. Hippocrates has ſeveral times preſcribed this under the name of *Molyza*, and this having ſome ſort of reſemblance to the word *moly*, ſeveral of the interpreters of Hipprocrates have been very deſirous of making it the ſame thing with the *moly* of Homer. But the words of Hippocrates himſelf, in his book of the diſeaſes of women, ſet this in a clear light; for he there adds the name of garlick to the *Molyza*, and orders a *Molyza* of garlick to be ſcraped clean for uſe. Heſychius calls *Molyza* a head of garlick, and Pſellus, on the antiquated words of the Greek phyſicians, ſays the ſame thing.

MOMENT (*Cycl.*)—A *Moment* ought not to be conceived as the leaſt part of time, but as a termination or limit of time. *Maclaurin's* Fluxions, vol. 1. p. 245.

MOMISCUS, a word uſed by ſome as a name of the *dentes molares*, and by others only as the name of that part of thoſe teeth which is near the gums.

MOMORDICA, in botany, the name of a genus of plants called by many authors, *balſamina* and *charantia*. The characters of the plants of this genus are theſe: The flower conſiſts of one leaf, ſhaped like a bell, wide open at the mouth, and deeply divided into five ſegments, ſo as to ſeem a five-leaved flower. Of theſe, ſome are male or ſteril flowers, having no embryo fruit, others are fruitful, and have each its embryo fruit at the bottom, which ripens into a capſule, more or leſs turbinated, fleſhy, hollow, and endued with an elaſtic power, by means of which it throws out the ſeeds on touching it, when ripe, to a conſiderable diſtance.

The ſpecies of this genus, enumerated by Mr. Tournefort, are theſe: 1. The common *Momordica*, called the round-leaved, male, or creeping *balſamina.* 2. The *Momordica* of Ceylon, with a ſhorter fruit, and a vine-like leaf. 3. The longer-fruited *Momordica* of Ceylon, with vine-like leaves.

The flower of this genus of plants is ſo very deeply cut into its ſegments, that there is ſome doubt whether it be not properly a five-leaved flower. The error of calling it *balſamina*, and confounding it with the ſpecies of that genus, is very great. See the article BALSAMINA.

MOMOT, the name of a bird deſcribed by Nieremberg, and ſaid to be an inhabitant of the hot countries. It is of the ſize of a pigeon; its beak is black and crooked, three fingers breadth long, and ſerrated at the edge. Its head is blue like the peacock's, and its feet brown. The reſt of the body is of a pleaſant green. But what is moſt ſingular in this bird, is, that it has in its tail one feather much longer than the reſt, which is naked for a great way, and is feather'd only at the end. This laſt circumſtance Mr. Ray judges wholly falſe, as no birds have ſingle feathers in their tails, but all that are there grow in pairs.

MONACANTHUS, in zoology, a name given by ſome to the alpheſtes, or cinedus, a fiſh approaching to the turdus kind; but differing, in that its back fin is prickly all along, whereas the forepart only is ſo in the turdus.

MONACHELLE, in ichthyology, a name given by ſome to the fiſh called, by the oldeſt Greek writers, the *chremps*, and by the later ones, as alſo by the Latin authors on theſe ſubjects, *chromis*. It is properly a ſpecies of the ſparus, and is diſtinguiſhed by Artedi from the others, by the length of the ſecond ray of the belly fins.

MONADELPHIA, in botany, a claſs of plants whoſe ſtamina or male parts, by reaſon of their filaments running in among one another, are all formed into one body.

The word is formed of the Greek μονος, ſingle, and ἀδελφὰ, brotherhood, or community. Theſe coalitions of the ſtamina in flowers being underſtood in botany by that term.

Of this claſs are the craneſbill, mallow, &c.

The general characters of this claſs of plants are theſe: There is always a perianthium to the flower, no ſpecies of the whole claſs being without it. This is always permanent, and ſurrounds the baſe of the ſeed-veſſel, after the flower is fallen.

The flower always conſiſts of five petals, which are cordated at the top. The ſtamina are a great number of filaments, which grow together in one body at the baſe, and are looſe at the top. The external ones are ſhorter than the others; and the antheræ are always incumbent. In the piſtils there is found a receptacle of the fructification, which is placed in the center of the flower. The germina are erect, and ſurround in a rotary manner the apex of the receptacle. The ſtyles are all found growing together at the bottom, into one body with the receptacle, and in their upper part they are divided into as many filaments as there are germina. The ſtigmata are ſlender and expanded. The fruit is a capſule, divided into as many cells as there were piſtils in the flower. This is of very various figures in the various genera and ſpecies; but the ſeeds in all are reniform, or ſhaped like kidneys. See Tab. 1. of Botany, Claſs 1.

This is an extremely natural claſs, and there is not one plant uſually allowed to belong to the reſt of this kind, that this character ſeparates, nor one of any other kind that it brings in among them. Tournefort has been guilty of a very great error, in regard to the flowers of the plants of this claſs; he ſays that they are monopetalous, and only divided into five ſegments; but a ſtrict obſervation will ſhew, that they really conſiſt each of five ſeparate petals, which only are joined at the baſe by certain filaments, which together make one body. Hence it follows, that they are ſtrictly and truly pentapetalous, tho' they fall off together, not ſeparately, on ſhaking the plant. *Linnæi* Gen. Pl. p. 325.

It is obſerved, that all the plants of this claſs are mucilaginous and emollient, and have great virtues, as diuretics, &c. The common marſhmallow deſervedly ſtands at the head of theſe, and is common in the preſcriptions of phyſicians on theſe occaſions, as well as in many of the ſhop compoſitions, as the ſyrrup of marſhmallows, and the like.

Tho' authors in general have kept this claſs of plants together, they have been much divided in their opinions, as to the characters or parts of them, by which they ſhould divide them into genera. Some have had recourſe, on this occaſion, to the ſeed-veſſel; others finding that inſufficient, have conſulted the leaves. Linnæus uſes the cup of the flower on this occaſion, which is a very eſſential part in this claſs of plants, and ſufficiently different in the different genera.

MONANDRIA, in botany, a claſs of plants which have hermaphrodite flowers, with only one ſtamen in each.

The word is formed of the Greek μόνος, ſingle, and Ἀνὴρ, male. Of this claſs of plants are the blite, turmeric, and the like. See Tab. 1. of Botany, Claſs 1.

MONARCHICI, in church hiſtory, heretics towards the end of the ſecond century, who allowed but one perſon in the godhead, and taught that the father was crucified. *Hofm.* Lex. in voc.

MONARDA, the name by which Linnæus calls the plant which is the *origanum ſpurium*, or baſtard wild marjoram of Rivinus. This, in the Linnæan ſyſtem of botany, makes alſo a diſtinct genus of plants, the characters of which are, that the cup is made of one leaf, and is cylindric and tubulated, with an even edge marked with five notches. The flower conſiſts of only one petal, which is a cylindric crooked tube, longer than the cup, and with a labiated opening. The upper lip is long, narrow, ſtrait, whole, and ſurrounded with rims; the lower lip is bent back, is broad, and ſlightly trifid, the middle ſegment being the longer, narrower, and rimmed round the edge. The ſtamina are two filaments, of the length of the upper lip of the flower, in which they are hid. The antheræ are of a compreſſed form, truncated above, and convex below. The piſtil is a quadrifid germen, with a thread-like ſtyle involved among the ſtamina, and a ſtigma bifid and pointed. It has properly no fruit, the cup encloſing in its bottom the ſeeds, which are roundiſh, and four in number. *Linnæi* Gen. Plant. p. 6.

MONEMERION, Μονημεριον, among the antient Romans, a ſhew, according to ſome, wherein none but tame beaſts were expoſed to view.

Others will have it to be a ſhew of one day's continuance. *Pitiſc.* in voc.

MONEY (*Cycl.*)—*Madning* MONEY. See the article MADNING.

MONGER, a little ſea-veſſel which fiſhermen uſe. Stat. 13 Eliz. c. 11. *Blount.*

MONK-*Fiſh*, the Engliſh name of a ſpecies of the ſqualus, according to the new Artedian ſyſtem; called *rhina* and *ſquatinus* by the old authors. It is diſtinguiſhed by Artedi from the other ſquali, by the name of the *ſqualus* with no *pinna ani*, and with the mouth on the top of the head. See Tab. of Fiſhes, N°. 7.

MONK'S *Hood*, a name given to ſeveral ſpecies of aconite, or wolfs-bane. See the article ACONITE.

The flowers of this plant are in common uſe in the country, to garniſh diſhes, tho generally ſuſpected of being poiſonous; but the ſtalks have been found very violently ſo, according to an account given in the Philoſophical Tranſactions, of a perſon who eat them inſtead of celeri.

The firſt ſymptom this perſon felt, was a biting, and ſenſation of a tingling heat, not only affecting his tongue, but his jaws;

jaws; his teeth, after this, seemed loose, and his cheeks were so much irritated, that he thought they were swelled to three times their natural size, and he could not be persuaded of the contrary by the people who were about him, nor by his glass. This tingling sensation by degrees spread itself farther, till by degrees his whole body, but especially the extremities, were affected by it; he then felt a weakness in his joints, especially in his knees and ankles, and frequent twitchings of the tendons. At length, he felt a pain that gave him an idea of the circulation of the blood being wholly affected, and absolutely stopped in his legs toward the feet, and from his wrists to his fingers ends. He had all this time no sickness, or disposition to vomit. He took near a pint of oil, and swallowed after that great quantities of carduus tea; this made him vomit; but after this his head grew misty, his eyes dim, and a humming noise was continually in his ears; after this he fell into absolute faintings, and his eyes were closed, his limbs stiff, and his teeth fixed. He was, however, recovered at length by repeated draughts of carduus tea, and cordial draughts of wine, with tincture of saffron, castor, and the like, between the times of his reachings to vomit. Philos. Transf. N°. 432.

The young shoots of this plant have some resemblance to salary, and were put into the salad as such. The whole quantity put in, was but the top of one root; and one other person eat of the sallad beside the man. She eat more sparingly, and had all the symptoms of which the man complain'd, only in a less degree.

MONOCEROS *Minor*, in ichthyography, the name of a fish caught in the American seas; its usual length is a foot and half; its height about nine inches, very flat bodied, and high backed like a perch, and bow bellied. Its head has some resemblance to that of a baboon. Its mouth is situated low, and is not above an inch over. Its teeth are of the eighth of an inch long, and of the thickness of a midling needle; and the gills are subtended to the eyes and mouth, like the segment of a circle. The eyes stand near the top of the head, and are an inch over. From the top of the head is prolonged a smooth, round, tapered, strait horn, two inches round about the root, and about three inches long. This seems to have no bone within it, nor is inserted into any, but seems merely the cuticle hardened, as in corns, into a sort of horny substance. The back fin reaches from the head to the tail. It is covered with a tough thick skin, feeling somewhat rough. *Grew's* Mus. Soc. Regal. p. 104.

MONOCEROS *Piscis*, is also used as the name of a fish, common in the American seas, and called *pira-aca* by Marggrave, and some other authors; and by the Portuguese, *piexe porto*.

It is a very small fish, of about three fingers breadth long, and two broad where broadest; it is of a flatted or compressed shape; the mouth is very small, but of the figure of that of a hog; and there are in the lower jaw only two broad teeth, and several small ones in the upper. The eyes are very large and yellow, with black pupils. A little behind the eyes, on the ridge of the back, it has an upright horn, a little bending backwards, less than a finger's breadth long, of a rounded figure, and of the thickness of a large thread; this is serrated on each side by a row of small teeth or prickles, their points bending downwards; and the whole horn seems supported by a small membrane, which is laid transversly on the back. It has a small furrow under each eye, in the cavity of which is placed a little fin; under the belly it has another larger fin, at the insertion of which there is also another horn like that on the back, but smaller. Its skin is very rough to the touch, and is of an obscure yellowish colour. The fins and the ridge of the back are yellower than any other part of it. See Tab. of Fishes, N°. 36. *Clus.* Exot. lib. 6. c. 28.

MONOCOLI, Μονόκωλοι, a kind of fabulous men, who, as the Arabians give out, inhabit the country of Segir in Arabia Felix. They are furnished with only half the head, breast and belly; and have but one eye, one ear, one hand, and one foot; notwithstanding which they can walk very swiftly, and even climb trees; talk with one another, and sing verses very elegantly composed. Their chief residence is said to be by the sides of lakes, or the sea shore. *Hofm.* Lex. univ. in voc.

The word is Greek, compounded of μονος, one, and κωλον, a member.

MONODON, in the Linnæan system of zoology, the name of the monoceros, or sea unicorn, a fish of the whale kind, which makes a distinct genus of fishes; the characters of which are, that it has no fin on the back, and a very long tooth in its upper jaw. *Linnæi* Syst. Nat. p. 51.

The word is Greek, compounded of Μονος, one, and οδους, a tooth, and expresses this fish's having only a single tooth. Artedi makes the *Monodon* a peculiar genus among the cetaceous fishes, or plagiuri. The *Narwal* is the only known species of this genus. See the article NARWAL.

MONOECIA, in botany, a class of plants which have not the male and female parts, that is, the stamina and pistillum in the same, but in different flowers; and those on the same individual, or on the different stalks, growing from the same root; those which contain the stamina are called the male flowers, those which contain the pistillum, the female ones.

The word is derived from the Greek, μονος, the same, and οἰκος, habitation. The plants of this class are the alder, mulberry, amaranth, &c. See Tab. of Botany, Class I.

MONOGASTRIC, in anatomy, a name given by Vieussens, and some of the French writers, to one of the muscles of the ear, called by Cowper, the *internus auris*; and more properly by Albinus, the *tensor tympani*.

MONOGRAPHI, in botany, authors who have written express treatises on only one plant; as Douglass on the Guernsey lilly, &c. *Linnæi* Fund. Bot. p. 1.

MONOMACHON, a name given by some to the intestine, otherwise called *cæcum*.

MONOMERES, a word used by the antients alone, but more frequently joined with the word *phorbeia*, to express one sort of the bandage used to confine the breath, by those who played on the antient pipe. This consisted only of one strait, and one transverse piece; and the latter came fully over the mouth, and closed it up, except that a hole was cut in it to receive the mouth-piece of the pipe. The *diemeres* consisted of several pieces, and only tied up the lower lip.

MONOPAGIA, a word used by some medical writers, for that species of headach which affects only one point, or small part of the head.

MONOPETALOUS (*Cycl.*)—See these flowers represented in Tab. I. of Botany, Class I.

MONOPHAGI, Μονοφαγοι, in antiquity, a designation given to those who celebrated the Æginean festival, because they feasted or eat together without the assistance of their servants; none but denizens of that island being allowed to be present. *Potter*, Archæol. Græc. l. 2. c. 20. T. I. p. 364.

MONOPODIA, among the antients, a sort of tables used in their feasts, and distinguished by this name from their having but one foot; the name being derived from the Greek, μονος, one, and πους, foot. *Hardouin*, in Plin. vol. 2. p. 641.

MONOPS, in natural history, a name given by Ælian, and some other of the old Greek writers, to the *bonasus*. It should appear from this name, which expresses a single eye, that the creature had but one eye; but this is not the case, and the word is rather formed upon the name *monopus*, which was originally written *monapus*, and the *a* only changed into an *o*, by the corruption of the copies of the authors who had treated of it. The name *monapus* was given this animal, according to Aristotle, by the people of the country where the creature was most frequent, and therefore is not to be attempted on any Greek etymology. Some of the Greeks have called the same creature *monepos*, and some *bolinthos*. See the article BONASUS.

MONOSCELI, Μονοσκελεις, a fabulous race of men, who are represented by Pliny to have only one leg. They were also called *sciapodes*. See the articles SICAPODES and MONOCOLI.

The word is Greek, compounded of μονος, one, and σκελος, a leg.

MONOSPERMALTHÆA, in botany, a name given by Mr. Isnard, in the *Acta Germanica*, to a genus of plants afterwards called *waltheria* by Linnæus. *Isnard*, A. G. 1720. See the article WALTHERIA.

MONOTROPA, in botany, the name of a genus of plants, called by Tournefort, *orobanchoides*, and by Dillenius, *hypopitis*. See the article OROBANCHOIDES.

MONRINGION, in botany, a name given by some authors to the tree whose fruit is the ben nut, and whose wood the *lignum nephriticum* of the shops. Hort. Mal. vol. 6. p. 19.

MONSTER (*Cycl.*)—The French Academicians have of late disputed whether *Monsters*, that is, creatures born with their organs preternaturally formed or situated, supernumerary or defective, were originally so formed in their first stamina; or whether this deformity has been owing to some accidental change upon them. The arguments for these opinions, are remarks on particular histories of such *Monsters*, which we cannot abridge, and therefore must refer to the Memoirs de l'Acad. des Sciences, 1733, 1734, 1731, 1739.

MONTENSES, a name given to the Donatists. See the articles CAMPITÆ, *Suppl.* and DONATISTS, *Cycl.*

MONTH (*Cycl.*)—Among the antient Greeks, the year was divided into twelve *Months*, which contained thirty and twenty-nine days alternately; but so as the *Months* of thirty days always went before those of twenty-nine; the former were termed πληρεις, full, and δεκαφθινοι, as ending on the tenth day; the latter were called κοιλοι, *hollow*, and from their ending on the ninth day, εναφθινοι.

In order to understand their method of reckoning the days of the *Month*, it must be considered that every *Month* was divided into τρια δεχημερα, or three decads of days; the first decad they called μηνος αρχομενε or ισαμενε; the second, μηνος μεσουντος; the third, μηνος φθινοντος, παυομενε or ληγοντος. Whence the first day of the *Month* was called νεομηνια, as falling upon the new moon, and πρωτη αρχομενε or ισαμενε, as being the first day of the first decad; the second day was termed, δευτερα ισαμενε; the third, τριτη ισαμενε; and so on to the δεκατη ισαμενε.

The first day of the second decad, which was the eleventh day of the *Month*, was called πρωτη μεσουντος or πρωτη επιδεκα; the second of this decad, δευτερα μεσουντος, or επιδεκα, and so on to εικας, the twentieth, which was the last of the second decad.

The

The firſt day of the third decad was termed πρωτη επ' εικαδι; the ſecond, δευτερα επ' εικαδι, and ſo of the reſt. Sometimes they inverted the numbers of this laſt decad, the firſt being called φθινοντος δεκατη; the ſecond, φθινοντος εννατη; the third, φθινοντος ογδοη; and ſo on to the laſt day of the *Month*, which was called Δημητριας, *Demetrias*, from Demetrius Poliorcetes; before whoſe time, particularly in Solon's laws, it was called ενη και νεα, *the old and new*; becauſe the new moon falling out on that day, part of it belonged to the old moon, and part to the new. It was alſo called τριακος, *the thirtieth*; and that not only in the *Months* which conſiſted of thirty days, but alſo in thoſe of twenty-nine; for in theſe, according to ſome accounts, the twenty-ſecond day was omitted; or, according to others, the twenty-ninth: But which day ſoever was omitted in computation, the thirtieth was conſtantly retained. Hence, according to Thales's firſt ſcheme, all the *Months* were called *Months* of thirty days; tho', by Solon's regulation, half of them contained only twenty-nine: And the lunar year of Athens was called a year of 360 days; tho' really, after Solon's time, it conſiſted of no more than 354. Vid. *Pott.* Archæol. Græc. l. 2. c. 26.

The names of the *Months* being various in different parts of Greece, it will be ſufficient particularly to conſider thoſe of Athens, barely mentioning thoſe of others that correſpond with them. 1. *Hecatombæon*, this was the firſt *Month* of the Athenian year, beginning on the firſt new moon, after the ſummer ſolſtice, and ſo anſwered to the latter part of our June, and the firſt part of July. It conſiſted of thirty days, and was by the Bœotians called *Hippodromus*, and by the Macedonians *Lous*; but its antient name was *Cronius*. 2. *Metagitnion*, the ſecond *Month* of the Athenian year, anſwering to the latter part of our July, and firſt of Auguſt. It contained only twenty-nine days, and was called by the Bœotians *Panemus*; and by the people of Syracuſe, *Carnius*. 3. *Boedromion*, the third *Month* of the Athenian year, which contained thirty days, and correſponded to the latter part of our Auguſt, and firſt of September. 4. *Mæmacterion*, the fourth *Month* of the Athenian year, conſiſting only of twenty-nine days. It anſwered to the latter part of our September, and firſt of October; and was called by the Bœotians *Alalcomenius*. 5. *Pyanepſion*, the fifth *Month* of the Athenian year: It contained thirty days, correſponded to the latter part of our October, and firſt of November; and was called by the Bœotians, *Damatrius*. 6. *Antheſterion*, the ſixth *Month* of the Athenian year, anſwering to the latter part of our November, and firſt of December. It contained twenty-nine days, and was called by the Macedonians *Dæſion*, or *Deſion*. 7. *Poſidion*, the ſeventh *Month* of the Athenian year, anſwering to the latter part of our December and firſt of January, and containing thirty days. 8. *Gamelion*, the eighth *Month* of the Athenian year; it anſwered to the latter part of our January and firſt of February, and conſiſted of twenty-nine days. 9. *Elaphebolion*, the ninth *Month* of the Athenian year, correſponding to the latter part of our February and firſt of March; it contained thirty days. 10. *Munychion*, the tenth *Month* of the Athenian year: It contained twenty-nine days, and anſwered to the latter part of our March and firſt of April. 11. *Thargelion*, the eleventh *Month* of the Athenian year: It contained thirty days, and anſwered to the latter part of our April and firſt of May. 12. *Scirrophorion*, the twelfth and laſt *Month* of the Athenian year: It contained twenty-nine days, and anſwered to the latter part of May and firſt of June. Vid. *Pott.* Archæol. Græc. L. 2. c. 26. & *Stephan.* Theſ. Ling. Græc. T. 5. p. 223. ſeq.

As the Roman *Months* were the ſame with thoſe now in uſe among the Europeans, we ſhall only refer to the article CALENDS, *Cycl.* and *Suppl.* where the manner of their computation is explained.

MONTIA, in the Linnæan ſyſtem of botany, the name of a diſtinct genus of plants; the characters of which are theſe: The cup is a perianthium compoſed of two oval, hollow, obtuſe and erect leaves, which remain when the flower is fallen. The flower is compoſed of three petals, joined together at their inſertion; theſe are of an oblong oval figure, and the two ſide-ones are larger and placed lower than the others. The ſtamina are three capillary filaments, of the length of the flower: The antheræ are ſmall: The germen of the piſtillum is of a turbinated form; the ſtyles are three, hairy and expanded, the ſtigmata are ſimple. The fruit is a capſule of a turbinated form, obtuſe, of one cell, ſeparated by three valves: The ſeeds are three in number, and roundiſh. *Linnæi* Gen. Plant. p. 21.

MONTIFRINGILLA, in zoology, the name of a bird known in Engliſh by the name of the *bramble*, *brambling*, or *mountain-finch*; and called by the antients *oroſpiza*. It is of the ſize and ſhape of the chaffinch; its beak is large, very ſtrong, and ſtrait, beginning with a large baſe, and ending in a point in form of a cone. Sometimes this is altogether black, ſometimes it is partly black and partly yellow; from the head to the middle of the back it is of the blackiſh colour of the common ſtarling, with a variegation of a greyiſh red from the edges of the feathers being of that colour; the hinder part of the back is white; the throat is of a reddiſh yellow, and the breaſt white. It is common in Italy, and is ſometimes found in England. *Ray's* Ornithol. p. 189.

There are beſide this, two other ſpecies of the *Montifringilla*, or brambling; the one large, of the ſize of the common lark, and having the claw of its hinder toe longer than the reſt, as in the lark; and the other a ſmaller, and ſeeming of a middle nature between the lark and brambling. It is reddiſh on the back, and white on the belly, and variegated with black and reddiſh brown on the wings. Theſe are both common in Lincolnſhire, and ſome other parts of England.

MONTROSE-*Waters*. Steel ſpaws are very numerous in the country about *Montroſe* in Scotland: The principal of theſe are at Aberbrothoc, Kincardin, and Peterhead [a]. That of Aberbrothoc is in greateſt eſteem [b].—[[a] Medic. Eff. Abr. Vol. 1. p. 106, 107. [b] Ibid. p. 111.]

Beſide theſe, there is a well near *Montroſe*, the water of which is of a whitiſh colour, ſoft taſte, and faintly diſcovering the mineral quality. This water is of a different nature from the ſteel-ſprings. The alcali prevails in its ſalt; it reſembles the Scarborough-water, and no ſalts come up to any analogy with thoſe of the *Montroſe* water, and thoſe of Scarborough, but nitre and ſea-ſalt. See Med. Eff. Vol. 3. Art. 8. Abr. Vol. 1. p. 112. ſeq. where various experiments with thoſe waters are enumerated, and a compariſon inſtituted between them and the Scarborough waters.

The water of this *Montroſe* well is univerſally diuretic; being drank from two to three pints, purges; and half the quantity ſucceeds with ſome. It has been found very uſeful in ſtranguries and ſtoppage of urine, ſcorbutic diſorders, flatulencies, ſpaſmodic colic, and ſpitting of blood. In rheums and ſtrains it has been of good uſe by way of cold pump, where perſons could not bear ſuch uſe of ordinary cold water. Med. Eff. Vol. 3. Art. 9. Abr. Vol. 1. p. 122. ſeq.

MONYCHA, an epithet applied by naturaliſts to thoſe animals whoſe hoofs are ſingle and undivided; ſuch are the horſe, and the like.

MOON (*Cycl.*)—It is commonly agreed among philoſophers and aſtronomers, that the *Moon* turns about the earth; but father Alexander ſuppoſes they may be all miſtaken, and that the earth really turns about the *Moon*; and from this extraordinary hypotheſis, he endeavours to account for the flux and reflux of the ſea. See Journ. des Scav. Oct. 1727.

Monſ. Grand-jean de Fouchy endeavours to prove, that there is no matter about the *Moon*, that can ſenſibly inflect the rays of light: And hence, that this ſecondary planet has no atmoſphere whoſe refraction is obſervable. It might indeed have a circumambient fluid, the horizontal refraction of which might amount to 1″ or 2″, and ſome obſervations may ſeem to give ground for admitting ſomething of this ſort. But with reſpect to aſtronomers the *Moon* may be ſaid to be deſtitute of an atmoſphere. See Phil. Tranſ. N°. 455. ſec. 3.

We have ſome obſervations and tables concerning the *Moon's* motion, by Mr. Richard Dunthorn, in the Philoſophical Tranſactions, N°. 482, ſec. 13. where he gives an hundred obſerved longitudes of the *Moon* compared with the tables, *viz.* 25 eclipſes of the *Moon*, taken (except the firſt) from Flamſtead's Hiſtoria Cœleſtis, the Philoſophical Tranſactions, and the Memoirs of the Royal Academy of Sciences; the two great eclipſes of the ſun in 1706, and 1715; 25 ſelect places of the *Moon*, from Flamſtead's Hiſtoria Cœleſtis; and 48 of thoſe longitudes of the *Moon*, computed from Flamſtead's Obſervations by Dr. Halley, and printed in the 1ſt edit. of the Hiſtoria Cœleſtis.

In the Philoſophical Tranſactions, N°. 473. we have a new method of computing the appulſes of the *Moon* to the fixed ſtars and planets; as alſo of eclipſes of the earth, commonly called eclipſes of the ſun, by Mr. Gerſten, profeſſor of the mathematics at Gieſſen.

The full *Moon* appears to the naked eye broader than a circular object ſubtending an equal angle ſeen by perfect viſion. In a *Moon* of three or four days old the illuminated part appears too broad, in proportion to the obſcure part, and likewiſe ſeems to extend more outwards, or to have a greater diameter than the obſcure part. Alſo in an eclipſe of the ſun or *Moon*, the bright part appears too broad in proportion to the dark part, and the eclipſe appears leſs than it really is.

This obſervation was made by Horrox, and is accounted for by Dr. Jurin, in his eſſay upon diſtinct and indiſtinct viſion.

MOON-*Eyes*, in the manege. A horſe is ſaid to have *Moon-eyes* when the weakneſs of his eyes increaſes or decreaſes according to the courſe of the *Moon*; ſo that in the wane of the *Moon* his eyes are muddy and troubled, and at new *Moon* they clear up; but ſtill he is in danger of loſing his eye-ſight quite.

MOON-*Fiſh*, a name given to the fiſh called by authors, *orbis*. See the article ORBIS.

MOP, in ſome counties of England, is the term for what is called the ſtatute in other places; being the time that young people who intend themſelves for ſervants, meet at ſome certain place, in order to be hired into ſervices. *Plot's* Oxfordſhire, p. 207.

MOOR (*Cycl.*)—MOORS, in the iſle of Man, thoſe who ſummon the courts for the ſeveral *ſheadings*; ſuch are the lords bailiffs:

bailiffs: Every *Moor* has the like office with our bailiff of the hundred. *King's* Descript. of the Isle of Man.

Moor-*Cock*, an English name for the red-game, or our lagopus, more commonly called the gor-cock. It is a very delicate bird, larger than a partridge, and common on the hills in Derbyshire and Yorkshire. *Ray's* Ornithol. p. 128. See the article Gor-*Cock*.

Moors-*Head*, in the manege. See the article More's-*Head*.

Moor-*Hen*, *Gallinula*, in zoology, the name of a genus of water-birds; the characters of which are these: The head is small, the body compressed, the beak short and moderately crooked, the wings small and hollowed like those of the common cock and hen kind, the tail very short, the legs long, and the toes remarkably so.

The common *Moor-hen*, called *Gallinula Chloropus* by authors, is a very well known bird, somewhat like the coot in shape, but smaller, and very much flatted in the body. Its feet are greenish, and its breast a lead-coloured blue; its belly greyish. It is common about our rivers, and is a very well tasted bird. *Ray's* Ornithol. p. 233.

Moor-*Land*, or Moory-*Land*, in agriculture, is a black, light and soft earth, very loose, and without any admixture of stones; and with very little clay, or sand.

The uppermost stratum of the fen-lands is usually of this earth, and it usually constitutes a moderately thick or deep bed. Intermixed with water it cannot easily be worked up into a paste; and when with labour worked up into somewhat of a firm mass, its surface appears spongy and porous; and as soon as dry, it easily moulders away to powder.

It is usually soft to the touch, unless it be worked very closely between the fingers, then it shews a mixture of a small quantity of sand, both to the touch and to the eye.

It seems indeed to consist almost entirely of pure vegetable matter, and this lying in such plenty on the surface of the fen-lands, is the cause of their being so very fertile.

The great disadvantage of the places which have this soil, is their being liable to be glutted with wet; and to remedy the inconveniencies arising from thence, the farmers who rent these lands have a custom of burning the soil at proper seasons. It burns very freely and easily, the surface readily catching flame, and a substance somewhat bituminous, usually contained among the soil, helps the burning. *Moreton's* Northamp. p. 36.

Moor-*Stone*, the name of a very remarkable stone found in Cornwall, and some other parts of England, and used in the coarser works of the present builders.

This is truly a white granite, and is a very valuable stone. It is a very coarse and rude, but beautiful congeries of variously constructed and differently figured particles, not diffused among, or running into one another, but each pure and distinct, tho' firmly cohering with whatever it comes in contact with. Its colours are principally black and white; the white are of a sort of marbly texture, and opake, formed into large congeries, and emulating a sort of tabulated structure; among these there are many of a pure crystalline splendor and transparence, and among these are lodged in different directions many small flaky masses of pure talcs of several colours; some are wholly pellucid, others of an opake white, others of the colour of brown crystal, and a vast number perfectly black. *Hill's* Hist. of Foss. p. 498.

It is found in immense strata in some parts of Ireland, but is disregarded there.

It is found with us in Devonshire, Cornwall, and some other counties; and brought thence in vast quantities to London. It never forms any whole strata there, but is found on the surface of the earth in immense and unmanageable masses; and to separate these into portable ones, they dig a hole with a wedge in some part of them, and surrounding it with a ridge of clay they fill it up with water; this by degrees soaks in, and finding its way into the imperceptible cracks so far loosens the cohesions of the particles there, that the day after they drive a larger wedge into the hole, and the stone breaks into two or more pieces. It is used in London for the steps of public buildings; and on other occasions, where great strength and hardness are required.

The people of Cornwall who have this stone in great plenty, use it in their tin-works, and particularly in their tin-kiln, on the good effect of which a great deal depends. This kiln is four-square, and at its top is placed a large block of *Moor-stone*; the usual size of this block is six foot in length and four in breadth; in the middle of this block there is made a hole of about six inches in diameter. This stone serves as a head to cover another like stone placed beneath it; but this under one is not so long as the upper by six inches. The reason of this is, that it must not reach the innermost or back part of the wall, which is the open place thro' which the flame ascends from another place below that, where a very strong fire of furze is constantly kept up; and there is another little hole also on the outside. The forepart is like a common oven, and has such a sort of chimney.

The tin ore is roasted in this kiln, to burn away the mundick, in this manner: The ore is brought in powder, and poured out in heaps on the surface of the top-stone, a man stands there and thrusts it down through the hole in this stone into the kiln, that is, to the surface of the under-stone; a person who stands below spreads this as it falls with an iron rake, and gives notice to the person above when there is enough down, that is when the surface of the lower stone is covered three or four inches thick. When this is done, the hole at the top is covered with green turfs, that the flame may reverberate the stronger; and the heat that the *Moor-stone* acquires helps to roast the ore; while the flame that comes up from the ore is blue, there yet remains mundic among it; but when this is burnt off, the flame is yellow. Philos. Transf. N°. 69.

The miners in some parts of Cornwall use the name *Moor-stone* for a sort of coarse free-stone, which lies very often over the tin ore; this is of a greyish colour, and is somewhat softer than that usually employed in building.

Moor-*Titling*, a commonog English name for the œnanthe, more frequently called the stone-chatter. See the article Stone-chatter.

MOORING (*Cycl.*)—Mooring *a fair Birth at Sea*, is *Mooring* in a place free from any annoyance.

Mooring *a Proviso*, at sea, is to have an anchor out, and a hawser a-shore; then the ship is *moored* with her head ashore. And two cables is the least, and four the best to *moor* by. See the article Anchor.

Mooring *Water-shot*, is to *moor* neither alongst nor athwart the tide, but quartering between both.

MOOSE-*Deer*. The first mention we find of this remarkable animal, is in a tract of Mr. Josselyn's, entitled New-England Rarities. That author says, it is a very fine creature, growing to twelve foot high; the horns are extremely beautiful with broad palms, some of those full grown being two fathom from the tip of one horn to the tip of the other. The same author, in another work, entitled, Two Voyages to New-England, calls this creature a monster of superfluity; and says, that when full grown it is many times larger than an ox. What Neal says of this animal seems copied from Josselyn. But the best account we have of it, is from Mr. Paul Dudley; this gentleman says, that they are of two kinds: The common light-grey *Moose-deer*, called by the Indians *Wampoose*, and the larger black *Moose*. The grey *Moose* is the same animal which Mr. Clayton, in his account of the Virginian quadrupeds, published in the Philosophical Transactions, calls the elk: And this is the creature, described in the Anatomical Discoveries of the Paris Academy, under the name of the stag of Canada. Horns of this creature have been sent from Virginia, and called elks horns: They are wholly the same with those of our red-deer, except in size; weighing about twelve pounds, and measuring from the burr to the tip about six foot long. Phil. Transf. N°. 444. p. 386.

Mr. Dudley says, that the grey *Moose* is like the English deer; and that these creatures herd together thirty or more in a company. The black or large *Moose* has been taken, he says, measuring fourteen spans in height from the withers, which, allowing nine inches to the span, is ten foot and a half.

The stag or male of this kind has a palmed horn, not like that of our common or fallow deer, but the palm is much longer and more like to that of the German elk; but it differs from that in having a branched brow antler between the burr and the palm, which the German elk hath not.

The large horns found fossile in Ireland, have, from their vast dimensions, been supposed to have originally belonged to the black *Moose-deer*; but they, as likewise most other of the large horns found in this part of the world, appear to be the horns of the German elk, having no brow-antlers.

Mr. Ray mentions, in his Synopsis of animals, a pair of extremely large fossile horns, which he saw in a musæum in Sussex; but he mentions no brow-antlers in these, and therefore probably they, as well as most others preserved in musæums, were the horns of the German elk.

It is not agreed by authors what number of young the *Moose* brings forth at a time; Mr. Dudley says but two; but Josselyn, and from him Neal, say three; and these authors add, that they do not go so long with young as our does, by two months.

There is, beside the *Moose*, another animal of the deer-kind, very common in Virginia, and other of the Northern provinces of America. This creature has round horns, not spreading out as in the stag or red-deer, but meeting nearer together at the tips, and bending forwards over the creature's head; and the brow-antlers are not crooked and standing forward, but strait and upright. The skin of this deer is of a sandy colour with some black hairs, and is spotted all over while young with white spots as some of our fallow deer are, and it is about the bigness of our fallow deer when full grown. The *Dama Virginiana* of Mr. Ray was different from this, if the description be exact, and the horns of the palmated kind. This *Dama* of Mr. Ray seems to be what Josselyn, in his Voyages, calls the *Maurouse*; but his description is too short to form any regular judgment from, he only says that the *Maurouse* is like the *Moose*, but that its horns are small, and the creature about the bigness of a stag. Phil. Transf. N°. 444. p. 388.

Josselyn mentions also the buck, the stag, and the rain-deer; but it is very much to be doubted whether they are the same animals

animals that we mean by thofe names. He mentions alfo another fort of American deer, an animal called a *Macarib*, a *Caribo*, or a *Pohano*; but this feems a mere fiction; no fuch animal exifting in nature.

MORBUS-*Comitialis*, the epilepfy, one of the moft terrible difeafes to which human nature is fubject.

The fymptoms of this diforder vary greatly in different perfons; fometimes it feizes them fuddenly, and unexpectedly; at others, it is preceded in every paroxyfm by a train of concomitant fymptoms, fuch as a general laffitude and wearinefs of the whole body, a pain in the head, great perturbation of the fpirits, and an unufual dread and terror; fometimes alfo a ringing in the ears gives notice of its approach, or an inflation of the præcordia or palpitation of the heart and difficulty of breathing. It is common alfo to feel a cold air as it were afcending from the extremities up to the heart and brain; fometimes the joints feel cold, and often rumblings are felt in the abdomen, and fetid ftools are difcharged.

In the fit, the thumbs are ufually faft clenched to the hands, the eyes diftorted, fo that only the white of them is feen, the patient is wholly fenfelefs, and a froth burfts out of the mouth with a fort of hiffing noife; the tongue is often lacerated by the teeth, and the joints ufually feel a violent fuccuffion. But fometimes violent fpafms feize all the limbs, inftead of thefe fuccuffions or tremblings; and they remain forcibly bent, fo as to make the patient refemble a ftatue of wood. In infants the penis is erected; in more grown perfons the femen is often ejected, and the urine difcharged to great diftances. And thefe fymptoms, fometimes fooner, fometimes later, gradually go off.

The paroxyfms, according to the diverfity of caufes, are longer or fhorter, and fewer or more frequent; but they generally return at ftated periods, as on certain days, hours, or months, or on the changes of the moon, efpecially at the new and full moon.

Women are ufually feized with thefe paroxyfms at the time of the return of the menfes; and what is moft obfervable is, that they are frequently occafioned by feemingly flight caufes, commotions of the mind, a colder feafon than ordinary, the ufe of ftrong liquors, clofe application of the mind to any thing, and finally, the ufe of venery, often bring on thefe fits. Infancy and youth are the times of life moft fubject to this diforder; and it more frequently attacks perfons of a nice and delicate conftitution, than thofe of a robuft and hardy make.

The caufe of this terrible diforder appears to be a ftricture of that membrane which furrounds the brain and the fpinal marrow. The caufes are very various, and thence alfo the difeafe varies in its fpecies and appearance. The moft terrible and mortal epilepfies have been brought on by external violence, by blows, wounds, fractures, and depreffions of the cranium. Thefe are generally preceded by pains of the head, and a torpor of the fenfes; and in thefe, after the patient's death, corrupted blood or ferum is always found either between the *dura* and *pia mater*, or between the *dura mater* and *cranium*. Chronical epilepfies, returning at ftated periods, are alfo frequently occafioned by certain acute bony protuberances arifing internally in the bafis of the cranium, and fometimes in the lateral finus. It is eafy to fee that this fpecies of epilepfy is incurable; yet medicine can do great fervice in it, by keeping the brain in fuch a condition, that its preffure on thefe protuberances may not be enough to produce a violent fit.

Polypofe concretions in the jugular veins, and obftructions of the finufes of the *dura mater*, are alfo caufes of incurable epilepfies. The paffions of the mind alfo, as anger, fear, and the like, contribute greatly to bring on epilepfies, as they act immediately upon the nervous parts, and either conftringe or dilate them preternaturally, which cannot be done very often without inducing a bad habit. Infants are often rendered epileptic either from fucking the milk of a nurfe in a violent fit of paffion, or from the violent commotions of mind the mother was fubject to while pregnant. The terror of the fight of one perfon in an epileptic fit, has frequently thrown another into the fame diforder; and it has been often known, that a ftrong propenfity to venery, from a natural redundancy of femen, being fuppreffed by chaftity, has brought on this difeafe. Women have fallen into it from violent love alfo, and have, in that cafe, found their cure in marriage.

In the cure of an epilepfy, the firft intention muft be to correct and expel from the body the remote material caufes of the diforder; fecondly, to mitigate the fpafms of the *dura mater* and nervous parts by medicines of a fedative and corroborating nature; the former, to check and allay the violent motion of the fluids, the other to reftore the due tone and natural elafticity to the parts, the weaknefs of which, occafioned by a former fit, gives frequent occafions for fucceeding ones. Of the firft kind are poppy-feeds or flowers, faffron, nutmeg, and the like; and among the chemical medicines, the *fpiritus nitri dulcis*, when truly prepared. Of the corroboratives to be given in epileptic cafes, rofemary, rue, lavender, cardamom feeds, and ambergreafe. Spirit of hartfhorn, and the oil of hartfhorn, made pure by frequent rectifications, is alfo greatly beneficial. The decoctions of the woods, as guaiacum, faffafras, and the like, are alfo good remedies: And feveral epilepfies have been known to be perfectly cured, by taking half a pint of a ftrong decoction of guaiacum twice a day, with a few drops of fpirit of vitriol in each dofe, and making all the while a weaker decoction ferve for the common drink. It is neceffary, however, if there be a redundance of blood, to begin the cure with frequent bleedings. Cupping on the parts near the head is alfo of great fervice, and fometimes the opening the jugular vein is neceffary, by which alone patients have fometimes been cured.

But tho' thefe are the methods of cure, in fome cafes, yet in others, where the difeafe has had a different origin, very different means are required. When an epilepfy arifes from an impure ferum, lodged in the veffels and membranes of the head; which too often happens from the fudden drying up of old ulcers, ftopping of iffues, or the like means; then the intention of cure confifts in the difcuffion, evacuation, and derivation of the ferum to other parts. For this purpofe cathartics are to be exhibited, and fetons. Iffues and bliftets are of fingular fervice. Nature has been known to cure epilepfies of this kind, by an eruption of pimples all over the body. And there is recorded in Willis a memorable inftance of a girl, fubject to frequent returns of epileptic fits; who, in one of them, happening to fall with her her head into the fire, and fo accidentally cauterifing it, remained well fo long as the ulcers difcharged any thing; but when they dried up, the former fits returned.

In epilepfies arifing from violent emotions of the mind, in which acrid, bilious, and acrimonious humours are conveyed into the nervous fyftem, the ufe of whey, mineral waters, and a proper regimen added to the fweetening powders, ufually produce a cure. Acidulated medicines are alfo highly proper, and fpirit of vitriol, or *fpiritus nitri dulcis*, are of very fingular efficacy. When an epilepfy arifes merely from pain, as that of the ftone, the tooth-ach when violent, or fpafms of the ftomach or inteftines, then clyfters of oil are of very great ufe; and after thefe, bleeding is ufually very proper.

In the epilepfies of infants, arifing from gripes, corrupted milk, or difficult dentition, great benefit is to be had from clyfters of milk with a little Venice foap diffolved in it. A few grains of cinnabar, given internally, often prove alfo of fingular benefit: And mufk is known to be a remedy fecond to none in thefe cafes. When Epilepfies are caufed by worms eroding the inner coats of the inteftines, after the ufe of the common anti-epileptic remedies, the medicines for worms muft be given, and their ufe continued, till, by the fymptoms ceafing, there is reafon to think thefe pernicious animals are deftroyed.

When an epilepfy returns at ftated periods, or at the changes of the moon, the caufe is ufually in the ftomach or duodenum, or its adjacent parts, the biliary ducts and pancreas. In this cafe therefore there fhould always be a clyfter given, and afterwards a vomit, before the expected fit.

In the time of the paroxyfms of epilepfies, people ought to abftain from the ufe of fubftances that are too volatile, fpirituous, fragrant, or fetid; for all thefe fill the head with vapours; nor fhould fuch things be exhibited as promote fneezing or vomiting, fince they derive the humours to the head, and often recall the paroxyfms. The moft ufeful means, in the fit, are to keep the patient in an erect pofture, to rub his hands and feet. In all kinds of epilepfies it is proper to abftain from wine and malt liquors, and to drink only water. Opiates, and too volatile medicines, muft be very cautioufly given to children, and to perfons of tender habits: And when epilepfies return on the flighteft caufes, it is proper to abftain from a load of medicines, and truft to nature and a proper regimen alone. In this regimen the patient muft abftain from all ftrong liquors, from great heat, or exceffive cold, from venery, from feeing any terrible fight, from anxiety of mind, and from bufinefs. Young perfons are to abftain from fruit; and all violent emotions of the mind are carefully to be avoided.

Many phyficians have prefcribed the root of the wild valerian, as a remedy which is alone capable of curing this terrible difeafe.

MORDEHI, an Eaft Indian name for a difeafe, to which the people of that country are fubject. It confifts in a violent diforder of the ftomach. The great heats, copious fweats, and fupervening cold of that country, all naturally tend to weaken the ftomach. Now if the inhabitants eat or drink immoderately at night, the concoction of their aliments can be but very unduly performed. Hence, befide this diftemperature of the ftomach, they are fubject to others of the bowels; and diarrhœas are very common among them, and with difficulty cured. *Hoffman*, de Morb. Endem.

MORDEXYN, or MORDOXI, a name given to a difeafe very frequent among the inhabitants of Goa, which confifts in a naufea, and continued vomiting, and ufually feizes the patient fuddenly and unexpectedly, and often proves fatal.

MORDILAPIS, a name given by fome writers to loaches, a fmall fifh, often found under ftones in fhallow waters.

MORE's-*Head*, in the manege, implies the colour of a *Roan horfe*, who befides the mixture or blending of a grey and a bay, has a black head, and black extremities, as the main and tail. See the article ROAN.

MORELLA, in botany, a name ufed by fome as a common term for all the nightfhades; others have appropriated it to the

lycoperſicon, or love-apple only. Æmilius Macer tells us, that in his time all the plants called by the Greeks *ſtrychna*, were called by the Latins *Morella*.

MORETUM, among the Romans, a kind of ſallad, compoſed of the eight following Ingredients, *viz.* garlic, parſley, rue, coriander, onions, cheeſe, oil and vinegar. *Pitiſc.* in voc.

MORGAY, an Engliſh name for the ſea fiſh called alſo the *rough hound-fiſh*, one of the galeus kind; the *catulus minor* of Salvian, and *muſtelus ſtellaris tertius* of Bellonius.

It is of a pale, and ſomewhat reddiſh grey, and is ſpotted with brown and whitiſh ſpots; the belly is ſilver white, and the body long and round; its ſkin is very rough, and its fleſh very firm, and finely flavour'd. Some ſay it taſtes of muſk, or ſome ſuch perfume. It is the ſmalleſt of all this genus of fiſhes, and ſeldom weighs above a pound and half. *Willughby*'s Hiſt Piſc. p. 64.

It is common in the Mediterranean, and is frequent in the markets in Italy.

MORGII, among the Mahometans, a ſect who lay much ſtreſs upon belief, and ſtand oppoſed to the *Alwaidii*. See the article ALWAIDII.

MORHUA, in zoology, a name uſed by ſome authors for the common cod-fiſh. *Bellon.* de Piſc.

MORIAM, in our old writers, a head-piece called a pot, Stat. 4 & 5 P. & M. c. 2. The word comes from the French *Morion*, or Italian *Morione*, *i. e. Caſſis*. *Cowel.*

MORILLON, in zoology, the name of a ſpecies of duck, ſeeming the ſame with the *capo roſſo*, a ſmall red-headed wild duck. See the article CAPO *Roſſo*.

MORINA, in botany. This plant, in the Linnæan ſyſtem, makes a diſtinct genus, the characters of which are, that the cup is double, and of two kinds, in the ſame plant; the one a perianthium of the fruit, which is monophyllous, cylindraceous, and remains after the flower is fallen off. The rim of this has ten notches in it, two of which have longer ſegments, which ſtand oppoſite to one another. The other cup is the perianthium of the flower, which is alſo compoſed of one leaf, and is of a tubular form, and ſlightly bifid, the ſegments being rimmed at their edges, pointed, and remaining alſo when the flower is fallen. The flower is a ſingle petal, forming a very long tube, a little bent, and wider at top than the bottom. The rim is plain, obtuſe, and divided into two lips; the upper of which is bifid, and the lower trifid. All the ſegments are of a roundiſh figure, and nearly equal in ſize. The ſtamina are too ſlender filaments, laid cloſe againſt the ſtyle, ſhorter than the flower. The antheræ are erect, and applied cloſely to one another. The piſtil has a roundiſh germen, placed under the receptacle of the flower; the ſtyle is of the ſame length with the ſtamina; and the ſtigma is formed into a ſmall head. It has properly no fruit; the ſeed ſucceeding each flower being ſingle, roundiſh, and ſurrounded with the cup of the flower. *Linnæi* Gen. Plant. p. 7.

MORINELLUS, in zoology, the name given by authors to the bird commonly called in Engliſh, the *dotterel*.

The uſual weight of this bird is a quarter of a pound; but the male is ſmaller than the female, and weighs uſually half an ounce leſs. Its Beak is a finger's breadth long. Its head is very beautifully variegated with ſmall black and white ſpots; and has a line of white over the eyes. Its throat is of a greyiſh white, variegated with ſtreaks of brown. Its breaſt and the under part of its wings are of a duſky yellow. The belly is white; and its back and wings are brown, with variegations of a whitiſh and yellowiſh colour. Its rump is grey; as is alſo its neck; and its tail is variegated with grey, black, and white. It is common in Lincolnſhire, and ſome other counties of England; and is a very delicate bird. It is commonly caught in the Night. *Ray's* Ornith. p. 230.

MORINELLUS *Marinus*, the *Sea Dotterel*, a name given by authors to the bird, commonly known in England by the name of the *turnſtone*; and called by Turner, *cinclus*. *Ray's* Ornithol. p. 231. See the article TURNSTONE.

MORINGA, in botany, the name by which ſome authors call the tree which produces the ben nut, or *glans unguentaria*, and whoſe wood is the *lignum nephriticum*, or nephritic wood of the ſhops.

MORION, in botany, a name given by the antients to a kind of nightſhade. The antient Greeks, Theophraſtus, and others, called all the nightſhades in general by the name *ſtrychnos*. Some of theſe they ſaid were poiſonous, and others eſculent. The poiſonous were of two kinds, ſome bringing on ſleepy diſorders, and others making the patient mad.

The eſculent kind was the *pomum amoris*, or love-apple, eaten at this time by the Portugueſe, and many other nations, and by ſome in England. Some after-writers uſed the word *Morion* as a diſtinctive name for thoſe kinds of nightſhade which cauſed ſleepy diſorders; and after theſe, ſome uſed it as the peculiar name of one ſpecies, and others as the name of the male mandrake of Dioſcorides, whoſe fruit, according to that author, was commonly eaten by the ſhepherds; but when taken too largely, threw them into ſleepy diſorders. From this word *Morion* has come, in all probability, the Latin name *morella*, given at firſt to the *pomum amoris*, or love-pple; and afterwards, according to Æmilius Macer, to all the nightſhades; for he expreſsly ſays, that thoſe plants which the Greeks called *ſtrychna*, the Latins called *morella*; and we find that the old Greeks called all the nightſhades *ſtrychna*.

MORION, in the natural hiſtory of the antients, a name given to one of the ſemi-pellucid gems, more commonly called *pramnion*. It is a ſtone appearing externally only of a fine deep black; but when held up againſt a candle, or againſt the ſun-ſhine, giving a very beautiful red, in different degrees, from that of the hyacinth to that of the amethiſt or carbuncle. *Hill's* Hiſt. of Foſſ. p. 471. See the article PRAMNION.

MORISONA, in botany, the name of a genus of plants, the characters of which are theſe: The perianthium is one-leaved, inflated, and divided at the top into two lips. Theſe ſtand open; but the neck is contracted, and the whole ſoon withers. The flower conſiſts of four oblong obtuſe petals, which are expanded when they are out of the cup. The ſtamina are numerous filaments. The antheræ are ſimple. The ſtyle is capillary and erect, and is longer than the tube of the flower. The germen of the piſtil is oval. The ſtigma is capitated, and of a plano-convex figure. The fruit is a globoſe berry, with a hard ſmooth rind. It has only one cell, and is ſupported by the ſtyle by way of pedicle. The ſeeds are numerous, and are of the ſhape of the common kidney-beans, but ſmall. *Plumier.* Gen. 23. *Linnæi* Gen. Plant. p. 230.

MORLING, or MORTLING, in our old writers, the wool which is taken from the ſkin of dead ſheep, whether killed, or dying of the rot, 4. Edw. 4. cap. 2. & 3. 27 Hen. 6. cap. 2. 3 Jac. 1. cap. 18. 14 Car. 2. c. 18. *Blount*, *Cowel.* See the article SHORLING.

MOROCHITES, in natural hiſtory, a name by which ſome of the old authors have called the *morochthus*, or French chalk. *Hill's* Hiſt. of Foſſ. p. 22. See the next article.

MOROCHTHUS, in the hiſtory of foſſils, a name of an indurated clay, commonly known among us by the name of French chalk, or marking-ſtone; and its principal uſe with us is the taking ſpots out of cloaths, and the ſerving taylors to mark with, as it makes a much more determinate and a neater line than chalk. The antients, however, had it much in eſteem in medicine, and uſed it as an aſtringent, and in colics and hæmorrhages, and externally in diſorders of the eyes.

It is diſtinguiſhed from all other earths, by being the hardeſt of all, conſiderably heavy, very ſmooth to the touch, and in colour of a greyiſh white, with a conſiderable admixture of green. It is of a diſagreeable brackiſh taſte, and does not ferment with acids. It is dug in Germany, the iſland of Sardinia, and many other places; but no where ſo plentifully as about Brianſon in France, whence it is there commonly called *Brianſon chalk*. *Hill's* Hiſt. of Foſſ. p. 22.

MOROCTES, one of the names by which Pliny, and ſome other of the older authors called the *Morochthus*, or French chalk. *Hill's* Hiſt. of Foſſ. p. 22. See the foregoing article.

MORONA, a name uſed by ſome for the *huſo*, or iſinglaſs-fiſh. *Willughby*, Hiſt. Piſc. See the article HUSO.

MORPHASMUS, Μορφασμος, among the antients, a kind of dance, wherein, by a great many figures, they imitated the transformations of Proteus. *Hofm.* Lex. in voc.

MORRHA, in natural hiſtory, a name given by ſome to the ſubſtance more properly called *murra* or *myrrha*, of which the cups called *murrhina* and *myrrhina* were made. See the articles MURRHINA and MORRHINA.

MORRHINA *Vaſa*, in the writings of the antients, a term very frequently met with, and uſed to expreſs a ſort of cup and vaſes uſed for drinking out of, and on ſome other occaſions.

The word is generally written *myrrhina*, and various conjectures have been formed concerning it, ſome ſuppoſing it to be meant of veſſels made of myrrh, ſome of the onyx, and ſome of a peculiar ſort of ſpotted ſtone. See the article MYRRHINA.

The word, however, is written by all the moſt correct writers *Morrhina*. Pauſanius and many others give us proofs of this. It is evident that there is no ſtone mentioned by the antients under the name *morrha*, nor is this word ever found uſed as a ſynonym for the onyx, or any other ſtone, but always as the name of the matter of which the veſſels were made.

The antients had many things in uſe among them, the nature and origin of which were unknown to them; and this *morrha* ſeems to have been one of that number. Some of them ſay it was a ſtone, and others call it a fluid, condenſed by being buried under ground. And if to this we add the beauty of the poliſh, the tender texture of the ſubſtance, which was eaſily broken by a fall, and the ſize of ſome of the veſſels made of it; for we are told that Heliogabalus had his chamber-pot made of it; it will appear very probable that it was a factitious matter, and was of the nature of our China ware. The antients, not knowing that the *morra* was a factitious ſubſtance, which it does not appear indeed that they did, does not prove it not to be ſuch; for they for many ages wore garments of ſilk, and had that ſubſtance in uſe on many other occaſions, and all the time believed it to be the *lanugo* or down of a tree, dreſſed by combing, &c. and it was not till

the days of Juſtinian that they knew it was ſpun by worms. Their ignorance of the origin of ſilk, however, no more altered its nature, than their ignorance of the fabric of their *morrhina vaſa* did that of the ſubſtance they were made of.

The antients had their moſt elegant and valuable *morrhina vaſa* from India and Carmania; but Arrian tells us, that there was a great quantity of them made at Dioſpolis in Ægypt. This he calls another ſort of *Morrhina* work; and it is evident, from all accounts, that the *morrha* of Dioſpolis was a ſort of glaſs ware, made in imitation of the porcelane or *morrha* of India.

There is ſome difference in the accounts given by Pliny and Martial, of the *Morrhina vaſa*. The firſt author ſays, that they would not bear hot liquors, but that only cold ones were drank out of them. The latter, on the other hand, tells us, that they bore hot liquors very well. It ſhould ſeem, that the moſt credit was to be given to Pliny; but if ſo, their porcelane was greatly inferior to ours in this particular.

MORSE, in zoology, the name of a monſtrous ſea animal, called by ſome the *roſmarus* and *walrus*, and by others, very improperly, the *hippopotamus* and *equus marinus*. See the article HIPPOPOTAMUS.

The *Morſe* is an ill-ſhaped amphibious animal, of the ſize of a large ox, covered with a ſkin like that of the ſeal, and ſomewhat reſembling an ox in the head; for which reaſon ſome have called it the ſea cow, or *vacca marina*, whence it has been erroneouſly confounded by ſome with the *manati*.

It has two large prominent and crooked teeth before, which are as fine as ivory, and are uſed by artificers for the ſame purpoſes. It brings forth uſually but one young one at a time, never more than two. It is a very ſtrong and vigorous animal, and difficultly taken; when it is caught, it is uſually at land, ſeldom at ſea.

Vorſtius, who met with a young one of this creature, has very accurately deſcribed it; whence we have the beſt deſcription extant of the nature of the animal. This young one was of the ſize of a large dog, and in ſhape much reſembled the phoca or ſea calf. Its head was round; its eyes large, and like thoſe of an ox; its noſtrils depreſſed and wide, and opening, and drawing together as the creature pleaſed. It had apertures on the ſides of the head for ears. Its mouth opened round and not very large; and on the upper lip it had a ſort of whiſkers, compoſed of thick cartilaginous briſtles. The lower jaw was of a trigonal form; the tongue ſhort and thick, and the mouth well furniſh'd with broad and flatted teeth. Its fore feet, as well as the hinder ones, were very broad; and the hinder extremity of its body very much reſembled that of the *phoca* or ſea calf. When it walked, the fore feet were directed forwards, the others turned backward. The toes were five on each foot, and theſe were joined by a membrane, which was remarkably thick. The hinder feet had claws, the fore ones had not; and the creature had no tail, and crept rather than walked on the hinder parts. Its ſkin was thick and tough, and covered with a few ſhort grey hairs. It made a noiſe like the grunting of a hog. *Ray's* Syn. Quad. p. 191.

MORT (*Cycl.*)—MORT, among the fiſhermen of ſome parts of England, a name given to the ſalmon while in its third year's growth. *Willughby's* Hiſt. Piſc. p. 189. See the article SALMON.

MORTALITY (*Cycl.*)—*Bills of* MORTALITY. Mr. Simpſon makes the proportion of the number of inhabitants of any place, to the number of births that happen there annually, as 26 to 1. Whereas Mr. Kerſſeboom [a] makes it 35 to 1; which Mr. Simpſon thinks owing to a want of obſervations. But Mr. Kerſſeboom has ſince ſhewn, in 29 tables, that the proportion of 26 to 1 cannot be admitted, and that his own, of 35 to 1, is right. He alſo proves, from Mr. Maitland's obſervations, that children in London, of two years old, continue to live, on a medium, above 37 years; and he obſerves, that by Dr. Halley's table [b], they live $38\frac{1}{2}$.—[a Doctr. of Annuit. p. 127. b Phil. Tranſ. N°. 465. Sect. 3. p. 319.]

Mr. Kerſſeboom ſuppoſes, that out of every 100 children born, five come dead into the world; and that out of every 100 children born alive, near 20 die under a year old. Mr. Simpſon's calculation differs greatly from this, he ſuppoſing that full 32 out of 100 children, die under a year old. Phil. Tranſ. ibid.

There is a ſurprizing diſparity obſerved between the chriſtenings and burials of the city of London; which is chiefly owing to diſſenters of all ſorts baptizing their children without ſending in accounts of their chriſtenings to the pariſh clerk. See Mr. *Maitland* in Phil. Tranſ. N°. 450. Sect. 16.

From the account there given of the chriſtenings and burials in London for ten years, from 1626 to 1635 incluſive, it appears that the chriſtenings exceeded the burials; nor can it be doubted that they do ſo ſtill. This obſervation will ſhew the cauſe of ſome miſtakes of Mr. Kerſſeboom. See Phil. Tranſ. ibid.

Mr. Maitland, in his account of London, ſhews, that at a medium of nine years, there are annually buried in London 29542, and in Paris only 17804; ſo that the number of inhabitants in London exceed thoſe in Paris by nearly in the proportion of 5 to 3. Hiſt. of Lond. p. 540, 548.

MORTAR (*Cycl.*)—The ſalt-petre workers in France uſing the *Mortar* of old buildings for extracting that ſalt, Mr. Petit has thought it worthy a peculiar attention, and has made ſeveral trials, by way of analyſis, of *Mortar*, to determine whether it really and eſſentially contains nitre in it, or whether it be only ſerviceable in that mixture of ſalts from which nitre is produced.

The common managers of the ſaltpetre-works are of opinion, that *Mortar* contains in it all the ſaltpetre they procure from it, and that the wood-aſhes, and other ſubſtances they uſe with it, only ſerve to abſorb the fat or oily parts, and ſo ſet the ſaltpetre at liberty to ſhoot. This they pretend to affirm upon experience; but they do not conſider that tho' they can procure ſaltpetre from the rubbiſh or *Mortar* without the addition of wood-aſhes, yet it is not pure *Mortar* that they make their experiments upon, but ſuch as is taken from their own heaps, upon which they always throw all the reſiduum of their former works, and all that liquor which will ſhoot no more cryſtals, but which they call the mother-water of ſaltpetre.

This gentleman therefore very properly judged, that to make a regular trial of the *Mortar* or rubbiſh alone, he muſt not take it from their ſtores, uſed in the ſaltpetre-works, but pick it himſelf from the ruins of old buildings.

The mark the ſalt-petre workers have to know good *Mortar* for their purpoſe, is, that it taſtes acrid and ſalt when applied to the tongue; but to this it may be alſo added, that it ought to be of a greyiſh colour, and ſuch as when powdered and ſprinkled upon burning charcoal yields ſome ſparks of fire; and the more ſparks it gives, the better it is for the purpoſe. And another character of the goodneſs is, that theſe well impregnated *Mortars* have a certain unctuoſity or fattineſs to the touch, which other kinds have not.

The fineſt of all kinds of *Mortar* for ſalt-petre work. is ſuch as is had from the ruins of old buildings in a low ſituation, and out of the way of much ſunſhine; where there has been no great quantity of fire kept, and eſpecially ſuch as has ſerved for the cements of the walls of ſtables, or the like.

Mr. Petit choſe from ſuch a wall twelve pounds of old *Mortar*; this he had beat to powder, and poured upon it eighteen pints of water; the whole was then ſet over the fire, and ſtirred from time to time for three or four hours, that the water might be well tinctured from the *Mortar*; after this the water was filtred through paper, and was then found to be tinctured to a pale yellow, tranſparent, bitter, and ſomewhat acrid to the taſte.

The impregnation may be made without heat, by only ſtirring the *Mortar* about for nine or ten days in cold water, and the quantity of the ſalts taken up will be according to the goodneſs of the *Mortar* and the quantity of water employed. The common ſpecific gravity of this liquor to water, is as 32 to 31, or thereabouts. Mr. Petit having procured the tincture of fifty pounds of *Mortar* by ſeveral impregnations in ſeventy-two French pints of water, evaporated it ſo far till it appeared highly charged with ſaline particles, taſting very acrid and bitter, and being of a browniſh red colour; and its ſpecific gravity was in this ſtate to water, as 4 to 3, there being more in quantity than about four pints. This was ſtill limpid and of a duſky colour, and was afterwards evaporated over a gentle fire to the conſiſtence of an extract, which as it cooled became much thicker and firmer, reſembling butter. This being left open to the air ſoon relented into a liquor of the conſiſtence of a ſyrup: Its ſpecific gravity was now to water as 5 to 3; but in leaving it open to the air, it continually attracted freſh humidity, and became leſs ſpecifically heavy. Experiments made with this extract ſucceeded in the following manner.

1. It turned the common blue paper to a fine deep red. The impregnations in water uninſpiſſated do this alſo in different degrees according to their ſtrength.

2. Mixed in equal quantities with ſpirit of nitre and with ſpirit of ſea-ſalt, it made no effervefcence or alteration in either.

3. A leaf gold being put into the mixture of this impregnation with ſpirit of nitre was immediately diſſolved, and in an hour or two afterwards the liquor was much clearer than before.

A leaf of gold being put into the mixture of this impregnation and ſpirit of ſea-ſalt, was in the ſame manner diſſolved in a few minutes. It is generally ſuppoſed indeed that ſpirit of ſalt alone will diſſolve gold, but there ſeems an error in this founded on the inaccuracy of the preparation of ſuch ſpirit of ſalt; for Meſſ. Geoffroy and Boulduc have at different times produced before the French Academy ſpirit of ſalt carefully prepared by themſelves, which would not at all diſſolve gold, not even with the aſſiſtance of heat; even ſuch ſpirit of ſalt would however be made to diſſolve gold by mixing this impregnation with it: So that it has the power of diſſolving gold in a great degree.

4. A leaf of ſilver being diſſolved in ſpirit of nitre, and this impregnation of *Mortar* added to the ſolution, the whole became turbid, and a precipitation happened, part of the matter

ter being thrown to the bottom, and part remaining suspended in form of a white cloud, which kept its place without falling.

5. The impregnation being mixed in equal quantities with oil of vitriol formed a coagulum, and made a great effervescence, with copious red vapours, and a strong smell of aqua fortis; and these vapours appeared at any time on stirring the mixture for several days together. If a larger quantity of oil of vitriol be added to this coagulum, it all becomes fluid, but ferments violently; and finally there will be a white matter precipitated to the bottom of the clear liquor; and if a leaf of gold be brought near this mixture it will be dissolved even by the vapour which exhales from it. Spirit of nitre has no effect upon this mixture, either in its state of a coagulum, or when reduced by more oil of vitriol into a clear liquor; but the volatile spirit of urine ferments violently without the least heat with it.

6. Oil of tartar *per deliquium* being added to the impregnation, the liquors would not readily mix, but remained separate, the impregnation sinking to the bottom; but on stirring them thoroughly together, they finally were made to unite into a white substance like butter, with a strong urinous smell. If a small quantity of corrosive sublimate be added to this mixture, the urinous smell ceases; and if oil of vitriol be added, there is a violent fermentation occasioned; and, in fine, a large quantity of precipitate.

7. This impregnation of *Mortar* being mixed with an equal quantity of a solution of corrosive sublimate, there is nothing remarkable produced, though the mixture be ever so much shaken; but if a little oil of tartar *per deliquium* be added to this, the mixture becomes turbid, and, on stirring all together for some time, it becomes white and thick like butter. If to this, more corrosive sublimate be added in solution, it becomes orange-coloured; and, on more stirring, this becomes again white; and finally gives a white precipitate at the bottom, of a transparent liquor.

8. If instead of oil of tartar an equal quantity of lime-water be added, this in the same manner gives an urinous smell, and the whole difference is, that the mixture will not become thick with this, as it will with oil of tartar.

9. The impregnation of *Mortar* produced the same coagulum on mixing with spirit of urine, that it did with oil of tartar *per deliquium*; but it made no coagulation with spirit of sal armoniac with lime; the occasion of this difference is, that the spirit of urine contains a great deal of volatile salt, and the other but little. It is a common error to suppose that the spirit of sal armoniac, which is most pungent, contains the greatest quantity of salt; but this is not the case, for the spirit made with lime is much more pungent than that with salt of tartar, though the last is well known to contain a greatly larger portion of saline particles.

10. If a piece of paper or linnen be wetted in this impregnation, and afterwards dried, it takes fire very violently, and sparkles with the same violence as if it was impregnated with salt-petre.

From these experiments it is abundantly proved, that the impregnation of *Mortar* contains a large quantity of a saline and nitrous ammoniac salt; for a dissolution of sal armoniac and spirit of nitre mixed together are found to produce all the changes in the different bodies before-named, that the impregnation does. On the whole, though it has been supposed by Mr. Tournefort, and others, that *Mortar* contained sal-petre, sea-salt, and a fixed alkali; yet there does not appear any proof of its containing any one of those salts; no fixed alkali can ever be separated from the impregnation of it; and tho' the linnen or paper wetted in the impregnation of it sparkled when on fire, yet it is not nitre, but merely a nitrous sal armoniac, which occasions that phænomenon. The same effect is produced, if the linnen or paper be wetted with a mixture of spirit of urine and spirit of nitre. And the several experiments before recited prove, that there is in *Mortar* a spirit of nitre and a spirit of sea-salt, which with the volatile urinous salts form a nitrous or a saline sal ammoniac. Mem. Acad. Scienc. Par. 1734.

MORTARIOLUM, a word applied by different writers to different things, from their resemblance to a mortar in shape. The chemists express by this name a small mould made for the fashioning their cupells; and anatomists call the sockets of the teeth the *Mortariola* of the jaws.

MORTIFICATION (*Cycl.*)— MORTIFICATION, in religion, any severe pennance observed on a religious account. How antient and how universal the practice of it has been, and for what reasons observed. See the article FASTING.

MORUS, the *Mulberry*, in botany, the name of a genus of trees, the characters of which are these: The flower is of the amentaceous kind, consisting of a great number of stamina, with their apices which arise from a four-leaved cup; these are male-flowers, and the embryo-fruits appear on different parts of the tree, and finally become a sort of compound berry, soft and full of juice, and composed of clusters of succulent squammæ which contain roundish seeds. *Tourn.* Inst. p. 589.

The species of *Mulberry*, enumerated by Mr. Tournefort, are these: 1. The common *Mulberry*, with black fruit. 2. The *Mulberry* with small black fruit, and elegantly divided leaves. 3. The *Mulberry*, with white fruit. 4. The *Mulberry*, with small purplish white fruit. And 5. The *Mulberry*, with small insipid white fruit.

The fruit of this tree, while unripe, is very astringent; but when thoroughly ripe, it is of a contrary quality, rather purgative, cooling, very pleasant, and quenching thirst. Its syrup, which is very pleasant, is the only use made of it in the shops.

The more general cultivating *Mulberry* trees in England might be of greater use than is at present supposed in many respects. In Devonshire they have a way of mixing *Mulberry* juice with their cyder in the making, and thus make the very best of all English vinous liquors. And as to the great article of breeding silk-worms, though a recommendation from the crown could not bring about the planting these trees in sufficient number for it in James the First's time, yet the trees have been found to flourish every where with us when properly planted, and the worms feed very kindly and work very well with us. When this manufacture was first attempted, the people of many parts of England, nay and in some parts of the dampest places in Ireland, tried it, and always with success. The only thing that stopped the progress of so valuable a thing at that time, was the want of a sufficient quantity of *Mulberry* trees, and the scheme has been neglected ever since. Phil. Trans. Nº. 133.

The tree was always esteemed by the antients for its delicious fruit, before the use of its leaves was ever found out. The Romans, in the height of their luxury, preferred it before all the foreign fruits; and Columella, and the other antients are very express in the methods of propagating it.

MORXI, the Indian name of a pestilential distemper, very common in Malabar, and in some other parts of the East-Indies, frequently carrying off great numbers of people.

MOSCH, a name of a sort of roriferous vessels, said to have been discovered by Bilsius, in the kidneys.

MOSCHELÆUM, a name given by authors to a compound, fragrant and aromatic oil, in which musk is a very predominating ingredient.

MOSCHATELLINA, in botany, the name of a little plant common under our hedges in spring, which constitutes a peculiar genus; the characters of which are these: The flower consists of one leaf, and is rotated and divided into several segments at the edge. From the cup of this rises a pistil, which is fixed in the manner of a nail to the middle of the flower; and finally becomes a soft succulent berry, containing flatted seeds. *Tourn.* Inst. p. 156.

MOSCHELAPHUS, in natural history, a name given by some writers to a creature of a mixed nature, produced by the copulation of a stag and a cow. Wagner tells us, that these creatures are sometimes seen in the mountainous parts of Swisserland; as are also the Hippotauri, generated between a bull and a mare; but neither of these ever propagate their species. *Wagner's* Hist. Helvet.

MOSCHIFERUM *Animal*, in natural history, the name of the creature which affords us the perfume called musk.

This creature seems to be neither of the goat nor deer-kind, and it is doubtful whether or not it chews the cud; it has however no *dentes incisores* in the upper jaw, which seems a mark that it does; but it has, according to the observation of Aristotle, exerted teeth or tusks there, in the manner of the boar. His nose is sharp, like that of a greyhound; his ears like a rabbit's, about three inches long, and erect; and his tail or scut, about two inches; his foot is deeply cloven. The hair on the body is about half an inch long, and very thick, and of a brown and white colour. *Ray's* Syn. Quad. p. 140.

The *Musk* bladder or bag is about three inches long and two over, swelling out an inch and half from the belly, and standing as much before the groin. It has no horns, and its tusks by their figure seem intended equally for feeding and fighting.

MOSCHOSITERON, a name given by Myrepsus, and other old writers, to Fœnugreek.

MOSS (*Cycl.*)—These small plants, tho' neglected of many ages, have, by the industry and application of the later botanists, been found a very numerous and very beautiful class of plants; and not without their uses in medicine and mechanics, and to various purposes of human life. Dr. Dillenius, who has studied them with an uncommon care, and given a very valuable history of them, has described more than six hundred species; the greater part of which are found in our own country, though some peculiar to others; and doubtless, there yet remain vast numbers unheeded and unknown in many countries. See Tab. of *Mosses*.

The *Mosses* of Virginia, Pensilvania, and other parts of North-America, are in part the same with ours, and in part different; about two thirds of the number of *Mosses* of these countries hitherto observed being common to our own country also, the rest peculiar to that part of the world. Those of South-America, are almost all wholly different from ours. The *Mosses* of Greenland and Lapland are mostly of the same kind with those of our Welch mountains. And in the moun-

tainous

tainous parts of the world between the Tropics, there are many extremely beautiful fern-like *Moſſes*, unknown in all other places.

Ireland and Scotland yet remain to be ſearched in a great meaſure, and probably will afford great numbers hitherto wholly unknown. It cannot but be acknowledged, that the diſtinctions of theſe little vegetables are ſo minute, and their appearance ſo various in their different ſtates, that very probably ſucceeding obſervations will much retrench the number deſcribed by Dillenius; but as the ſame obſervers will probably add as many new and truly diſtinct ſpecies, as they find occaſion to ſtrike off from the old liſt, there is no doubt but that the number will be found at leaſt as great as it ſtands at preſent with that author.

Uſes of Mosses. Were there no other uſe in theſe minute and beautiful objects than the admiring the wonderful works of the creator, this were enough to make the ſtudy of them worthy of attention; the almoſt endleſs variety of the figure and ſtructure of their leaves, the ſlenderneſs of the ſtalks that ſupport them, and the regularity and nice order in which they are arranged; the minuteneſs of their roots, and the ſlenderneſs of the pedicles which bear the heads, each of which is often ſmaller than the fineſt hair, and the extreme exility of the veſſels through which juices are conveyed along theſe for the nouriſhment of the plant and ſeeds, can never enough be admired; and the various ſtructure of the heads or ſeed-veſſels with their coverings, by means of which the tender ſeeds and farinæ are defended, afford to the microſcopic obſerver an endleſs fund of admiration.

But theſe are not all the uſes they were intended for, many may yet remain unknown; but we at preſent well know that ſeveral of the uſneas are great and valuable medicines, uſed as deſiccatives and aſtringents; that the common cup *Moſs* is one of the greateſt remedies in the convulſive coughs of children, called the chin-cough, is known to every one; and Dr. Mead has ennobled the grey ground-lichen, by publiſhing its virtues in one of the moſt terrible of all diſeaſes, the bite of a mad dog. The common green liverworts are known medicines in diſorders of the breaſt, as are alſo all the ſpecies of polytricha. The ſeeds of our lycopodium are given with ſucceſs in nephritic caſes; and the Indians give one of their ſpecies in many diſtempers, and as they ſay, with great benefit. The common white ground coralloides ſerves the rain-deer of Lapland for food, when all other herbage is loſt; and the confervæ ſerve for food to many of the fiſhes both of the ſea and rivers, and to ſeveral water-fowl. And theſe, as well as the land *Moſſes* afford ſhelter and habitation to many inſects, and their young. Many of the ſpecies of coralloides and lichenoides are found of great uſe in that profitable branch of commerce the art of dying; and doubtleſs many others have alſo the ſame qualities, though not yet diſcovered; and we may be guided in ſearches of this kind by obſerving that many of them tinge the papers between which they are dried, to very beautiful and laſting colours. The *Moſſes* which cover the trunks of trees, as they always are freſheſt and moſt vigorous on the ſide which points to the north, if not only produced on that, ſerve to preſerve the trunk of the tree from the ſeverity of the north-winds, and direct the traveller in his way, by always plainly pointing out that part of the compaſs.

The ſoft marſh and bog *Moſſes* ſerve the poor in many places for ſtuffing their beds, and in the buſineſs of tranſporting plants from other countries; nothing is of ſo great uſe as the ſtalks and leaves of theſe little vegetables: The ſucculent plants coming over in great beauty and vigour when rolled up in dry *Moſs*; and trees and ſhrubs, by having their roots covered with ſuch as is ſomewhat moiſt.

The great quality of the *Moſſes*, which makes them ſo ſerviceable in this caſe, is, that they do not heat and ferment on being moiſtened, as hay and ſtraw would.

Characters of Mosses. What the botanical writers ſtrictly underſtand by the word *Moſs*, is a claſs of plants appearing of an inferior rank, to the common vegetables; the leſs perfect genera of which ſeem to be wholly deſtitute of flower or ſeed or any thing analogous to either, at leaſt as far as our obſervations have hitherto been able to carry us, and to conſiſt of ſimple, ſimilar, and uniform parts; the genera a little above theſe have ſome diverſity of parts, and carry ſomething that looks analogous to vegetation in the common way, having a reſemblance of thoſe parts which ſerve other plants for their fructification. The more perfect genera of the *Moſſes* not only conſiſt of different parts, but have alſo their appropriated organs containing a pulpy matter, which finally becomes dry, and aſſumes the form of a fine and ſubtle powder, compoſed of granules, each of which is either a ſeed or a granule of farina ſerving for the propagation of the ſpecies.

The more imperfect *Moſſes* are diſtinguiſhed from the others by their appearance to the naked eye; they are either in form of a fine lanugo, or down covering the ſurface of different bodies, or elſe they appear as ſlender filaments or foliaceous bodies floating about in the water, or as filaments of a tougher texture hanging down from the branches of old trees, or as little ſhrubs or ſingle horns growing erect on the parched earth of mountains and heathy places; or finally, as broad and foliaceous bodies ſpreading themſelves over the dry barks of trees or rocks, without any pedicle or other ſupport.

The more perfect kinds of *Moſſes* are found in the ſhape of ſmall but regular plants, dividing into ſeveral branches, and clothed with leaves; theſe are of various forms and ſtructures, ſome being broad and thin, others ſlender as hairs; ſome pellucid, others opake; ſome ſmooth, others hairy. From the alæ of theſe leaves in ſome kinds, and from the ſummit of the ſtalks in others, there ariſe heads or capſules of a various figure and ſtructure, but all unicapſular; ſome of theſe are naked, others covered with a calyptra or hood; ſome ſtand on long pedicles, and others are placed cloſe to the ſtalks. Theſe heads are uſually called *capſulæ*, and their pedicles *ſetæ*, in the *mnia*, *hypna*, *brya*, and *polytricha*; but in the *lichenes* and *lichenaſtra* the pedicles are called *pediculi*, and the heads *capitella*.

The *byſſi*, *confervæ* and *tremellæ*, appear to be wholly deſtitute of ſeeds; the ſeveral parts of theſe genera have no difference from one another; and in the *tremellæ*, though there is often an appearance of leaves like thoſe of trees, yet when examined they will be found to differ in this, that the upper and under ſides are no way different.

The *uſneæ*, *coralloides*, and *lichenoides*, all have ſomething which ſeems analogous to a flower or fruit in the perfect plants; and all the other genera of *Moſſes* as the *ſphagna*, *hypna*, &c. have perfect fructifications, and produce the powder before-mentioned ſerving in the place of farinæ or ſeeds, and regularly propagating the plants. The mnia, lycopodioides, and above all others the lichens or liverworts, have perfect and regular fructifications obvious to the eye. The mnia have duſty heads, which appear plainly to be the female part of the fructification.

The lycopodioides has ſeveral capſules containing farinæ, and beſide theſe ſeveral female capſules containing ſeeds, and not farinæ, interſperſed along the ſame ſpikes.

The heads of the lichens or liverworts which contain the farinæ, differ from all the others in that they are polycoccous; in this alſo they differ from the ſeed, bearing heads of the ſame plants or ſcyphi, as they are called, which are ſingle, and contain the rudiments of ſeeds, obvious to the naked eye, which may be daily ſeen to encreaſe; and the propagation of the plant from them is eaſily obſerved through its ſeveral ſtages: This however is very ſingular, and extremely different from that of all other plants, in that the whole operation conſiſts only in the dilatation of the ſeeds, they having no heart or eye, as it is called, in the ſeeds of the larger plants, no place from whence the radicle is to ſhoot, nor any ſeminal leaves, but expanding ſimply into breadth, they become young plants like the parent.

The other genera of *Moſſes* have all capſules for the containing their ſeed or farinæ. Theſe, in ſome, are covered with a calyptra or hood, in others they are naked. Of the firſt kind are the *ſphagna*, *brya*, *fontinales*, *hypna*, and *polytricha*; and of the latter, the *ſelagines*, *lycopodia*, *poroniæ*, *anthocera*, and *lichenaſtra*.

The capſules of the *ſphagna* have no calyptra, becauſe the heads being placed on extremely ſhort pedicles, and the leaves of the plant long, they are covered and defended by them; and having beſide a very rigid and ſtiff operculum, they are in no neceſſity of any other covering; but the *fontinales*, *hypna*, *brya*, and *polytricha*, are all defended in their capſules by calyptræ, leſt the too abundant humidity ſhould deſtroy the ſeeds. The operculum ſlides off from all theſe in a tranſverſe direction; for when the included pulp in the capſule becomes ripened into ſeeds or farinæ, the notched parts of the rim ariſe from the ſurface, and expand themſelves outward, by means of which the operculum is at liberty to fall off, and the ſeeds have liberty to fall out, and propagate the plants.

The *ſelagines*, *lycopodia*, and *lycopodioides*, have neither capſule, operculum, nor calyptra; for the fruits of theſe genera lying immerſed in the alæ of the leaves, they need no ſuch coverings; but they ſtand naked cloſe to the ſtalk, and when mature, they open longitudinally, and throw out their ſeeds. The fruits of the anthocera open in the ſame manner, but they are of a very different figure, reſembling pods, whereas the others are of a kidney-like ſhape.

The poroniæ are very ſingular, in that their capſules are perforated with many holes, thro' which the ſeeds or farinæ are diſcharged when ripe. The heads of the lichenaſtra, when they are ripe, become lucid, and opening into four parts, carry the appearance of a tetrapetalous, or four-leaved cruciform flower.

The ſubſtance with which the heads or capſules of all the *Moſſes* are filled, reſembles either ſeeds, or the ſmall globules of the farinæ of flowers, which all reſemble ſeeds of particular figures in miniature. The fructifications of theſe minute plants ſeem to be either from theſe, as ſeeds falling to the earth; or, according to the opinion of ſome, they ſeem to contain only farinæ in the capſules, which impregnating certain bulbs or nodules in the alæ of the leaves, cauſe them to grow and vegetate, as is ſeen in ſome of the larger plants, as in the bulbs produced in the alæ of the leaves of the dentaria, and of the lillies, and ſome others. The former opinion, of the powder in the heads or capſules, being actually perfect

perfect feeds, is the more probable, as thefe bulbs in the alæ of the leaves are found only in fome of the hypna, and others of a few other genera, whereas the propagation is as quick and certain in thofe which have none of them, as in thofe which have; and the want of female parts of fructification, which makes fo many defiderata in the Linnæan fyftem of botany, is eafily made up, and the whole explained according to the ufual courfe of nature in other vegetables, by allowing the powder in the capfules to be real feeds, and the fmall globules on the pointals furrounding the aperture of the capfule, the farina.

The opinion of the *Moffes* growing only from thefe nodules in the alæ of the leaves, or from the impregnated ends of the branches which had received the powder from the capfules, was originally founded on the obferving, that the trailing or branched hypnums annually grew out into length, from the extremities of all their branches, and annually loft as much of the old ftalk at the root, as they gained of the new at the fummit; but it appears from further obfervations, that they are real feeds which are contained in form of powder in the capfules; fince the bryums, and many others, are found growing from fmall points or fpots, which are affemblages of their minute leaves, propagated on the ground, under the old ones juft where the powder of the capfules has fallen; and tho' it be allowed, that the hypnums and other trailing *Moffes* do grow from the ends of the branches, yet they may alfo be produced in form of new plants, from regular and perfect feeds fhed from the capfules. It is certain that the bryums are by this means propagated and fpread into large tufts, and the other genera may alfo be fo propagated, tho' they have befide a property of encreafing by growth of the ftalk; which feems no other than the property of many of the larger plants to creep at the root, and fhoot out in length greatly from the extremities of their horizontal branches, lying on or under the ground, as thofe fpreading parts may more properly be called than roots, the fibres pufhed out from them perpendicularly into the earth, being properly the roots; and it is well known that thefe plants, tho' they propagate themfelves thus by the root, produce feeds alfo like the others, by which they may be equally propagated; and this analogy is to be carried yet farther; for as thofe plants which creep by the roots, produce fewer feeds than thofe which are propagated only by feeds, fo the hypnums, which are the genus of *Moffes* in which this growth by the ftalk is principally obferved, are very thinly befet with capfules of feed, and many of them produce but very few in a feafon; whereas the brya, and other *Moffes*, which have not this advantage of growing from the ends of the ftalks, are found every year profufely covered with capfules from every tuft; nay, there is fcarce any branch which does not produce its capfule. Now if thefe capfules contained only a farina capable of impregnating the nodules, or the ends of the branches, it is obvious there would be as much of it required for the hypna as for any other kinds of *Moffes*; but if they are real and perfect feeds, it is no wonder that nature has given them profufely, to fuch kinds as are to be propagated only by feeds, and more fparingly to thofe which are propagated alfo by the increafe of the branches.

To this it may finally be added, that the ferns and other epiphyllofpermous plants approach moft of all others to the nature of the *Moffes*; and tho' it has been fufpected by many, that the fine powder at the back of their leaves was not feeds, but only a farina; yet it is now well known that it is true and perfect feed, fince, under many fpecies of them, there are conftantly found new and felf-fown plants arifing in their firft rudiments of leaves and figure, which have plainly grown from the duft or powder fallen from the old plants; and as this is now found to be the cafe in regard to the ferns, probably it will alfo appear the fame in regard to the *Moffes*, when they have been yet farther examined than at prefent. But whether thefe grains of powder have the lobes and radicle by which the feeds of larger plants propagate themfelves, or whether they grow into plants like the parent ones, in the manner of the lichens, by mere expanfion, is a thing that requires farther obfervations to determine.

Some of the *Moffes*, it is evident, approach to the nature of the plants, which have their male and female parts in the fame flower, and to thofe which have them in different ones. The lichens have their leaves notched and jagged like thofe of the perfect plants, and have, in the fame manner, their under furface different from the upper. Thefe have their male flowers or heads on long pedicles; thefe heads contain only farina, and the feeds are lodged in little cups or difhes on the furface of the leaves. The next in perfection to thefe are the lycopodioides, which have flowers with farina, and fruits with feeds, difpofed along the fame fpike. The mnia have heads of two kinds, the one membranaceuus, like thofe of the hypnums and other *Moffes*, and the other dufty, and containing a powder vifible on their furface; the one of thefe plainly contains the farina, the other the feed. The lichenaftra are very feldom found with feeds on them; but they creep greatly by the roots; whence a new propagation by feeds is lefs neceffary. The polytricha are fuppofed to carry only a farina in their heads, and their branches ftellated at the ends, tu carry the feeds which are to be impregnated. This has been the common opinion; but it wants confirmation. Some of the bryums have the fame appearance of a female part, and the young nodules in the alæ of the leaves of the hypnums are generally alfo referred to the fame ufe. But thefe are conjectures; and the much more probable opinion is, that the powder in the heads of all the *Moffes* is true feed, which in general is impregnated with farina from the pointals, over the mouth of the capfule; and in fome inftances, as in the mnia, &c. as in fome of the more perfect plants, from different flowers in a different part of the plant. *Dillen.* Hift. Mufc. Introit.

The manner of feeding of *Moffes* in general may be in fome degree gueffed at by that of one genus of them, which has been traced through all its ftages, and to which moft of the others, though every genus has its diftinct fructification in fome refpects, yet bear a very great general analogy.

The genus already obferved, is that called by Dr. Dillenius, the *hypnum.* The fpecies of this are very numerous and common; but that particular one which was the fubject of thefe obfervations, is the fhort-branched filky kind, common on old walls; and called by that author in his hiftory, *Hypnum vulgare, fervicum, recurvum, capfulis erectis cufpidatis.*

The head of this *Mofs* appears to the naked eye a fmall fmooth brownifh yellow oblong body, of about a ninth of an inch long; this is covered at its upper end with a membranaceous calyptra or hood, in fhape refembling an extinguifher, or a funnel inverted. When this calyptra is taken off, and the head viewed with a microfcope, the furface of it is feen to be ridged with longitudinal ftriæ. The bafis of the head is of a deep orange colour, and more opake than the reft; and the top is bounded by an orange-coloured ring fwelling out fomething beyond the furface of the contiguous parts of the head. Good glaffes fhew that in this head there are not wanting the parts effential to the fructification of what are ufually called the more perfect plants. This ring is truly a monophyllous undulated calyx, within which arife fixteen pyramidal fimbriated ftamina; thefe are of a pale greenifh colour, and are loaded with a whitifh oval farina. The ftamina all bend toward each other from their bafes, and almoft meet in a point at their tops. This is their appearance when the head is nearly ripe; and immediately under the arch formed by thefe ftamina, is a cylindric hollow piftillum, through which the farina makes its way, and is difperfed among the feeds in the head. The fruit is a large capfule, filling every part of the membrane which fhews itfelf on the outfide of the head, and in moft places is contiguous to it. This capfule is filled with perfect and very beautiful feeds; they are round, tranfparent when unripe, but afterwards opake, and of a very beautiful green, which colour they retain even when dried. Philof. Tranf. N°. 478. Sect. 12.

When this head is firft produced fiom the plant, the ftamina are very flender, and ftand erect; the head is fcarce any thicker than the ftalk, and the calyptra covers it all over, to fhield the tender fubftance of the farina from external injuries. As the farina afterwards fwells in the ftamina, the feeds in the head increafe alfo in bulk, and by their increafe the head is more extended in thicknefs, and the ftamina are by this means feparated farther and farther from each other at their bafes, but bend inwards toward their points, fo as to form a kind of arched covering over the ftigma of the piftillum which is fingle; and from hence the farina falls as it ripens into the head, and impregnates the feeds. Id. Ibid.

All the *Moffes*, liverworts, and the other plants of the fame character, poffefs the fame general virtues of drying and aftringency.

Moss *on Trees*, in gardening. The growth of large quantities of *Mofs* on any kind of tree is a diftemper of very bad confequence to its increafe, and much damages the fruit of the trees of our orchards.

The prefent remedy is the fcraping it off from the body and large branches, by means of a kind of wooden knife, that will not hurt the bark, or with a piece of rough hair cloth, which does very well after a foaking rain. But the moft effectual cure, is the taking away the caufe. This is to be done by draining off all the fuperfluous moifture from about the roots of the trees, and may greatly be guarded againft in the firft planting of the trees, by not fetting them too deep.

If trees ftand too thick in a cold ground, they will always be covered with *Mofs*; and the beft way to remedy the fault, is to thin them. When the young branches of trees are covered with a long and fhaggy *Mofs*, it will utterly ruin them; and there is no way to prevent it, but to cut off the branches near the trunk, and even to take off the head of the tree, if neceffary; for it will fprout again; and if the caufe be in the mean time removed by thinning the plantation, or draining the land, the young fhoots will continue clear after this.

If the trees are covered with *Mofs*, in confequence of the grounds being too dry, as this will happen from either extreme in the foil, then the proper remedy is the laying mud from the bottom of a pond or river, pretty thick about the root, opening the ground to fome diftance and depth to let it in; this will not only cool it, and prevent its giving growth to any great quantity of *Mofs*, but it will alfo prevent the other

other great mifchief which fruit-trees are liable to in dry grounds, which is the falling off of the fruit too early. *Mortimer*'s Hufbandry, vol. 2. p 78.

Heath-Moss. See the article Heath.

Silk-Moss, in botany, a name given by Count Marfigli to a fpecies of fea *Mofs*, of a very remarkable finenefs and foftnefs, much more refembling filk than any other of the vegetable productions. It is wholly compofed of a fort of tuft of fine hairs or filaments, and is of a bluifh green colour, and almoft tranfparent. It grows on rocks, ftones, fhells, or any thing elfe that lies in its way, and is found ufually at fmall depths; it is not fo tough and flexible as many other of the fea plants, but is eafily rubbed to powder between the fingers. When examined by the microfcope, the fingle filaments do not appear of the fame equable furface and uniform texture; but they are feen to be jointed and made up as it were of a great number of pieces faftened end by end to one another, in the manner of the beads of a lady's necklace. It is of a fine bluifh green, and perfectly tranfparent before the microfcope, and refembles a ftring of gems, fuch as the aqua marina, or fome other like ftone. *Marfigli* Hift. de la Mer. p. 79.

Sea-Mosses. Thefe fmall plants are very beautiful when viewed by the naked eye; but when examined with the microfcope, they afford a very pleafing variety of ftructure and conformation.

The common kinds afford a great variety of colouring, the different parts of the fame plant often appearing fome brown, fome yellow, fome red, and fome grey. On drying, thefe colours become lefs elegant; but on putting the dried plant again to foak in water, they are in fome degree recovered, and the variations are ufually found to be owing to the joints and knots in the ftalks, which interrupt the courfe of the general colour, and are often themfelves either black, or of a dark and deep brown.

The fummits of their branches are frequently terminated by little tranfparent bubbles; thefe fome have taken for fruit, but very erroneoufly; they are in reality only globules of clear water. Some of them are jointed at feveral diftances, and every joint has its regular fhape and ftructure. This is the cafe in the two great claffes of the corallines and the confervas. Others are elegantly variegated with brown, yellow, and green, and though lefs tranfparent, are not lefs beautiful than the former; thefe are in general of the fucus or fucoides clafs. Others are white and tranfparent, like *Moffes* of cryftal. Thefe are fmall and elegant corallines, and their joints are ufually variegated with black fpots: It is not unufual alfo to fee, at the extremities of the branches of thefe, certain fmall black globules, which appear to be the fruit; but they are in reality no other than globules of water thus tinged by fome juices from the plant.

It is poffible, however, that thefe liquid globules may be fo far of the nature of a fruit, as to contain the feed of the plant. We know that the feeds of the fea fucus's in general are enveloped in a glutinous liquor, and kept at the fummit of the branches of the plant; they are indeed in thofe large plants furrounded with a vifible and fenfible membrane, which is indeed thicker and longer than any other part of the plant; and it is not impoffible that thefe fine and fmall globules may have their covering membrane, too fine and thin to become the object of our fenfes. *Marfigli* Hift. de la Mer, p. 80.

The generical characters of thefe plants are to be feen under their feveral heads of *fucus*, *coralline*, and the reft; but thefe minute plants are often omitted by the writers on botany, though they make fo elegant a figure on being viewed with the affiftance of glaffes.

Moss is alfo a name given by fome to the boggy ground in many parts of England, more ufually called a *fen* and *bog*.

In many of thefe grounds, as well in England and Ireland as in other parts of the world, there are found vaft numbers of trees ftanding with their ftumps erect, and their roots piercing the ground in a natural pofture, as when growing. Many of thofe trees are broken or cut off near the roots, and lie along, and this ufually in a north-eaft direction. People who have been willing to account for this, have ufually refolved it into the effect of the deluge in the days of Noah; but this is a very wild conjecture, and is proved falfe by many unanfwerable arguments. The waters of this deluge might indeed have wafhed together a great number of trees, and buried them under loads of earth; but then they would have lain irregularly and at random; whereas they all lie lengthway from fouth-weft to north-eaft, and the roots all ftand in their natural perpendicular pofture, as clofe as the roots of trees in a foreft.

Befide, thefe trees are not all in their natural ftate, but many of them have the evident marks of human workmanfhip upon them, fome being cut down with an ax, fome fplit, and the wedges ftill remaining in them; fome burnt in different parts, and fome bored through with holes. Thefe things are alfo proved to be of a later date than the deluge, by other matters found among them, fuch as utenfils of antient people, and coins of the Roman emperors.

It appears from the whole, that all the trees which we find in this foffile ftate, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elfewhere. It may appear indeed an objection to this opinion, that moft of thefe foffile trees are of the fir kind; and that Cæfar fays exprefly, that no firs grew in Britain in his time; but this is eafily anfwered by obferving, that thefe trees, though of the fir kind, yet are not the fpecies ufually called the fir, but pitch-tree; and Cæfar has no where faid that pitch-trees did not grow in England. Norway and Sweden yet abound with thefe trees, and there are at this time whole forefts of them in many parts of Scotland, and a large number of them wild upon a hill at Wareton in Staffordfhire to this day.

In Hatfield marfh, where fuch vaft numbers of the foffile trees are now found, there has evidently once been a whole foreft of them growing. The laft of thefe was found alive, and growing in that place within feventy years laft paft, and cut down for fome common ufe.

It is alfo objected by fome to the fyftem of the firs growing where they are found foffile, that thefe countries are all bogs and moors, whereas thefe forts of trees grow only in mountainous places: But this is founded on an error, for though in Norway and Sweden, and fome other cold countries, the fir-kinds all grow upon barren and dry rocky mountains, yet in warmer places they are found to thrive as well on wet plains. Such are found plentifully in Pomerania, Livonia, and Courland, &c. and in the weft parts of New England there are vaft numbers of fine ftately trees of them in low grounds. The whole truth feems, that thefe trees love a fandy foil; and fuch is found at the bottoms of all the *Moffes* where thefe trees are found foffile. The roots of the fir-kind are always found fixed in thefe, and thofe of oaks, where they are found foffile in this manner, are ufually found fixed in clay, fo that each kind of tree is always found rooted in the places where they ftand in their proper foil; and there is no doubt to be made, but that they originally grew there. When we have thus found that all the foffile trees we meet with once grew in the places where they are now buried, it is plain that in thefe places there were once noble forefts, which have been deftroyed at fome time; and the queftion only remains how and by whom they were deftroyed. This we have reafon to believe, by the Roman coins found among them, was done by the people of that empire, and that at the time when they were eftablifhed, or eftablifhing themfelves here.

Their own Hiftorians tell us, that when their armies purfued the wild Britons, thefe people always fheltered themfelves in the miry woods, and low watery forefts. Cæfar exprefly fays this, and obferves, that Caffibelan and his Britons, after their defeat paffed the Thames, and fled into fuch low moraffes and woods, that there was no purfuing them; and we find that the Silures fecured themfelves in the fame manner when attacked by Oftorius and Agricola. The fame thing is recorded of Venutius, king of the Brigantes, who fled to fecure himfelf into the boggy forefts of the midland part of this kingdom: And Herodian exprefsly fays, that in the time of the Romans pufhing their conquefts in thefe iflands, it was the cuftom of the Britons to fecure themfelves in the thick forefts which grew in their boggy and wet places, and when opportunity offered, to iffue out thence and fall upon the Romans. The confequence of all this, was the deftroying all thefe forefts, the Romans finding themfelves fo plagued with parties of the natives iffuing out upon them at times from thefe forefts, that they gave orders for the cutting down and deftroying all the forefts in Britain which grew on boggy and wet grounds. Thefe orders were punctually executed; and to this it is owing that at this day we can hardly be brought to believe that fuch forefts ever grew with us as are now found buried.

The Roman hiftories all join in telling us, that when Suetonius Paulinus conquered Anglefea, he ordered all the woods to be cut down there, in the manner of the Roman generals in England: And Galen tells us, that the Romans, after their Conqueft in Britain, kept their foldiers conftantly employed in cutting down forefts, draining of marfhes, and paving of bogs. Not only the Roman foldiers were employed in this manner, but all the native Britons made captives in the wars, were obliged to affift in it: And Dion Caffius tells us, that the emperor Severus loft no lefs than fifty thoufand men in a few years time, in cutting down the woods, and draining the bogs of this ifland. It is not to be wondered at, that fuch numbers executed the immenfe deftruction which we find in thefe buried forefts. One of the greateft fubterranean treafures of wood is that near Hatfield; and it is eafy to prove that thefe people to whom this havock is thus attributed, were upon the fpot where thefe trees now lie buried. The common road of the Romans out of the fouth into the north, was formerly from Lindum (Lincoln) to Segelochum (Little-Burrow upon Trent), and from thence to Danum (Doncafter), where they kept a ftanding garrifon of Crifpinian horfe. A little off on the eaft, and north-eaft of their road, between the two laft named towns, lay the borders of the greateft foreft, which fwarmed with wild Britons, who were continually making their fallies out, and their retreats into it again, intercepting their provifions, taking and deftroying their carriages, killing their allies and paffengers, and difturbing their garrifons. This at length fo exafperated the Romans, that they were determined to deftroy it; and to do this fafely and effectual-

ly, they marched against it with a great army, and encamped on a great moor not far from Finningly: This is evident from their fortifications, yet remaining.

There is a small town in the neighbourhood called *Osterfield*, and as the termination field seems to have been given only in remembrance of battles fought near the towns whose names ended with it, it is not improbable that a battle was fought here, between all the Britons who inhabited this forest, and the Roman troops under Ostorius. The Romans slew many of the Britons, and drove the rest back into this forest, which at that time overspread all this low country. On this the conquerors taking advantage of a strong south-west wind set fire to the pitch trees, of which this forest was principally composed; and when the greater part of the trees were thus destroyed, the Roman soldiers and captive Britons, cut down the remainder, except a few large ones which they left standing, as remembrances of the destruction of the rest. These single trees however could not stand long against the winds, and these falling into the rivers which ran through the country, interrupted their currents, and the water then overspreading the level country made one great lake, and gave origin to the *Mosses* or moory bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the vast increase of water *Moss*, and other such plants which grow in prodigious abundance in all these sort of places. Thus were these burnt and felled trees buried under a new-formed spungy and watery earth, and afterwards found on the draining and digging through this earth again.

Hence it is not strange that Roman weapons and Roman coins are found among these buried trees; and hence it is that among the buried trees some are found burnt, some chopped and hewn; and hence it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-east, that is, in that direction in which a south-west wind would have blown them down: Hence also it is, that some of the trees are found with their roots lying flat, these being not cut or burned down, but blown up by the roots afterwards when left single; and it is not wonderful, that such trees as these should have continued to grow even after their fall, and shoot up branches from their sides which might easily grow into high trees. Philos. Trans. N°. 275.

By this system it is also easily explained why the moor soil in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat-earth or bog-ground is well known, and the soil added by overflowing of waters is not a little.

As the Romans were the destroyers of this great and noble forest, so they probably were also of the several other antient forests; the ruins of which furnish us with the bog-wood of Staffordshire, Lancashire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the isle of Man, or in Ireland; it is not to be supposed, that forests cut down by these people gave origin to the fossile wood found there; but though they did not cut down these forests, others did; and the origin of the bog-wood is the same with them and with us. Holingshead informs us, that Edward the First being not able to get at the Welch, because of their hiding themselves in boggy woods, gave orders at length that they should all be destroyed by fire and by the ax; and doubtless the roots and bodies of trees found in Pembrokeshire under ground, are the remains of the execution of this order. The fossile wood in the bogs of the islands of Man and Anglesea, is doubtless of the same origin; though we have not any accounts extant of the time or occasion of the forests there being destroyed; but as to the fossile trees of the bogs of Ireland we are expresly told, that Henry the Second, when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests by cutting away the places of resort of rebels.

Moving-Moss. We have an account in the Philosophical Transactions, of a moving-*Moss* near Church-town in Lancashire, which greatly alarmed the neighbourhood as miraculous. The *Moss* was observed to rise to a surprizing height, and soon after sunk as much below the level, and moved slowly towards the south.

Wall-Moss. See the article Wall-*Moss*.

MOSTRA, in the Italian music, a little mark set at the end of each line of a tune, thus  to shew that the first note of the next line is in that place.

If this first note be accompanied with a ♯ or flat *b*, it is right to place those characters with the *Mostra*. Also if in a thorough bass this first note have any cyphers, it would be of use to put the same cyphers with the character, at the end of the preceding staff. Again, if the part change its cleff with the first note, the cleff ought to be marked with the *Mostra* in the same manner. The *Mostra* is of great use, especially in quick motions, as it prepares the player for what is to come. Vid. *Brossard*. Mus. Dict. in voc.

MOSYNÆCUM *Æs*, in metallurgy, a name given by the antients to a white metal made of copper, in great esteem among them.

Aristotle tells us, that it was extremely bright and of a perfect fine white colour; and adds, that it was made of copper by melting it with an admixture of a peculiar kind of earth. Strabo also mentions this; and Theopompus tells us, that it was made of copper and an earth, and that it looked so like silver, that it was generally called *Pseudoargyron*.

Virgil mentions it under the name of *Aurichalcum album*, and seems to give it great praises. We are not able at present to say what it was they used in making it. We know several things that will render copper white, as arsenic, and the like; but none of these can well be supposed to be the thing. For arsenic, and all the things we use to make our factitious metal, debase the copper, and render it brittle; whereas by the accounts of Strabo, and others, their white metal seems to have been better for all uses than the copper itself. As to their telling us that it was a sort of earth which they used on this occasion, very little regard is to be paid to the terms; for they had an inaccuracy of speaking that leaves us much in the dark, in many other things beside this. They called the *calaminaris* stone, which is an ore of zink, by the name of *Cadmian* earth, in their description of the manner of making brass.

It has seemed absurd to some to call this white metal *aurichalcum album*, because they suppose the word *auricalchum* to signify gold-coloured copper; but this is an error. The *aurichalcum* is but a false spelling of *orichalcum*. See the article Orichalcum.

MOTACILLA, the *Waterwagtail*, in the Linnæan system of zoology, the name of a large genus of birds, of the order of the passeres; the distinguishing characters of which are these: The tongue is jagged, and has a rim or margin round it; the beak is strait, and pointed, and the hinder claw is of the same length with the rest, by which alone it is sufficiently distinguished from the lark kind. Of this genus are the wagtail, the red-breast, wren, nightingale, &c. *Linnæi* Syst. Nat. p. 49.

Mr. Ray enumerates three species of *Waterwagtail*, the white, the yellow, and the grey. The first is the most common, and well-known kind. The yellow one is of the same shape and size with that, but is beautifully variegated with yellow and green: this builds among the corn. The third or grey one is of the same size with the others, and is the most clamorous and noisy of them all. It is principally variegated with black and grey, but has some yellowness, especially about the rump. *Ray's* Ornithol. p. 171, 172.

MOTETTO, in the Italian music, a kind of church-music, composed with much art and ingenuity from one to eight parts, with or without instruments, usually accompanied with a thorough bass. When the composer gives a loose to his fancy, without confining himself to any rules, subjects, or passions, it is called *Fantasia*, or *Ricercata*. See the articles Fantasia, and Ricercata.

The word is sometimes used for pieces made to hymns to saints, &c. and whole psalms are often thus called. Vid. *Brossard*. Mus. Dict. in voc.

Field-MOTH. See the article Tinea *Campestris*.

MOTHER-*Wort*, *Cardiaca*, in medicine, is only used in the shops as an ingredient in some of the compound waters, intended against hysteric complaints; and the country people frequently make an infusion of it in the manner of tea, for the same purpose. It is also said to be good in flatulencies, and colics, to give great relief in epileptic cases, and to destroy worms. It promotes urine, and the menses; but its power this way is greatly inferior to that of penny-royal. See the article Penny-*Royal*.

The name *Cardiaca*, improperly given to this plant, has led many into an opinion of its being a cordial; but experience does not shew any such thing. See the article Cardiaca.

Mother *of Vitriol*. See the article Vitriol.

MOTION (*Cycl.*)—*Laws of* Motion. Of three laws of *motion*, which consist in the preservation of 1°. *The relative velocity* in the collision of elastic bodies, that is the difference of the velocities of those bodies moving the same way, and the sum when they move in contrary directions. 2°. The quantity of direction; see the article Direction. 3°. The sum of the product of the masses by the squares of the velocities. Two of these laws being granted, the third follows necessarily. Thus, let A and B be two bodies, their velocities before the shock a and b, and after the shock x and y. Suppose first that before and after the shock the bodies move the same way, the first law of conservation gives $a-b=y-x$; the second $Aa+Bb=Ax+By$: Hence by transposition $a+x=y+b$ and $Aa-Ax=By-Bb$; and these two equations multiplied together give this new one, $Aaa-Axx=Byy-Bbb$, or by transposition, $Aaa+Bbb=Axx+Byy$. And it is plain, that if a or b, as well as x or y, be taken negatively to signify that the bodies A and B move in contrary directions before and after the shock, this supposition will not alter the signs of the equation $Aaa+Bbb=Axx+Byy$. *Bernoulli* Oper. Tom. 3. p. 57.

The preservation of the same quantity of *motion* in the universe, was a principle laid down universally by Descartes; but has been found false, and holds true only in the same direction, which is thus expressed by Sir Isaac Newton: "The "quantity

" quantity of *motion*, which is collected by taking the ſum " of the *motions* directed towards the ſame parts, and the " difference of thoſe that are directed to contrary parts, ſuf-" fers no change from the action of bodies among them-" ſelves." *Newt.* Princip. lib. I.

Some philoſophers, after Deſcartes, have ſuppoſed the preſervation of the ſame force or *vis viva*. See the articles FORCE, and VIS *Viva*.

But this holds only in elaſtic bodies, when there is a ſhock; and hence thoſe philoſophers have been led to maintain, that all bodies were elaſtic, at leaſt in their elements, and that an inflexible body was impoſſible, being repugnant to the law of continuity. See the article CONTINUITY.

MOTION *of the Limbs.* See the article LIMB.

MOTION, in the antient muſic, was uſed to ſignify the tranſition of the voice, from an acute to a grave ſound; or the contrary. This they expreſſed by κατα τοπον κινεισθαι. *Wallis*'s Append. ad Ptolem. Harmonic. p. 153. See the article LOCUS.

Meibomius tranſlates it, *moveri in loco*.

MOTION, in the manege. A horſe is ſaid to have a pretty *Motion*, when he moves and bends his fore-legs with great eaſe and freedom upon the manege. But if a horſe trots right out, and keeps his body ſtraight, and his head high, and bends his fore-legs handſomely, then to ſay he has a pretty *Motion* with him, implies the liberty of action of the forehead.

Muſcular MOTION. Dr. Browne Langriſh endeavours to prove that the blood has no immediate effect in *muſcular Motion*, by experiments of tying the crural and carotid arteries of dogs, who did not thereby loſe the action of any muſcles. He grants however, that when all the blood is intercepted, *muſcular Motion* ceaſes in a few minutes. The chief uſe of the blood towards *muſcular Motion*, is to keep the fibres warm, ſupple, diſtended, and ready for the influx of animal ſpirits into them, and by its *Motion* to aſſiſt theirs.

The muſcular fibres are little hollow cylinders, not divided into cells; the animal ſpirits are near a-kin, or analogous to ſpirit of ſal ammoniac, *&c.* and therefore, whenever they fly from the nerves into the muſcular fibres, they will increaſe the attractive quality of their component particles towards each other, ſo as to make them run nearer together, which will occaſion the coats of the fibres to be both thicker and ſhorter, and the muſcle will be contracted in all its dimenſions. The animal ſpirits are too ſubtile to be fixed, and therefore immediately make their eſcape through the fibres, and leave them in the ſame ſtate they found them in, as ſoon as the ſupply by the nerves is diſcontinued. There is a difference in the mechaniſm of the nerves ſent to the muſcles, which act by the influence of the mind, from thoſe of the muſcles which are ſaid to perform involuntary motions, the latter having no hindrance to the courſe of the animal ſpirits, unleſs ſometimes the parts through which they paſs have influence on them; whereas the nerves, which ſerve the muſcles of voluntary motion, have ſome little conſtrictions at their extremities, or elſewhere, which hinders the courſe of their fluids, except when their reſiſtance is overcome by the momentum of the ſpirits being increaſed by the will. The uſe of the ganglions is to prevent any communication of *motion* from one nerve to another, whereby in a ſtate of health, ſenſation is always performed diſtinctly. Eſſ. on Muſc. Motion.

Dr. Stuart having cut off the head of a frog, obſerved, that upon thruſting a probe into the *medulla ſpinalis*, the muſcles of the body were brought into convulſive contractions. And that the ſame happened to the muſcles of the head, when the probe was thruſt into the brain. From which he concludes, that the brain and nerves contribute to *muſcular Motion* in a high degree. Next he laid bare the crural artery, vein, and nerve of a dog, and placing a thread parallel to them, made two ligatures on them, at four inches diſtance from each other; then cutting the veſſels through, beyond the ligatures, he took them out, and obſerved, that the nerve did not contract, though the blood-veſſels loſt three eighth parts of their length. From whence he infers, that what the nerves contribute in *muſcular Motion*, cannot ariſe from, or be owing to elaſticity, but to the fluid they contain, which can be no other than a pure elementary water. Phil. Tranſ. N°. 424. §. 5.

Rythmical MOTIONS, a phraſe uſed by Voſſius, and other writers on the antient rythm, to expreſs thoſe *motions* which were made uſe of in the Greek and Roman entertainments to convey the ideas of the poet, or to aſſiſt muſic in rouzing the paſſions. Theſe not only had great force when joined with ſounds, but even without any voice or ſound they could move the paſſions in the ſpectators, more than many of the beſt orators of the times could do with their moſt laboured diſcourſes.

Roſcius, the ſtage-player ſo famous in their pantomimes which were all dumb ſhew, was ſo excellent at expreſſion by theſe *rythmical Motions*, or geſtures, that Cicero and he being cotemporaries there were many diſputes between them, which could vary the ſame ſentence moſt; the one uſing all the power of words, the other being confined to geſtures alone.

MOTION, *Moto*, or *Movimento*, in the Italian muſic, has many ſignifications; ſometimes it means only a *Motion* or paſſage from one note to another, at whatſoever diſtance, as a ſecond, third, or any other interval; and is the ſame whether the intermediate degrees (if there are any) be ſounded or only the extremes of them, as the firſt and laſt ſound of any given interval. Sometimes it regards the quickneſs and ſlowneſs of ſuch *motions*, as a briſk, ſlow, lively, or languid *motion*; and in this ſenſe it is uſed with regard to minuets, gavots, ſarabands, *&c.* See each article in its proper place, and MOTION, *Cycl.*

But the moſt common, and indeed the moſt important acceptation of the word, is with reſpect to harmony; thoſe above deſcribed only regarding melody. See the articles MELODY, and HARMONY, *Cycl.*

With regard to harmony, it is the comparing the manner wherein an upper or treble part moves from one ſound to another, with that wherein a lower or baſs-part moves; this is to be done three ways. The firſt is when the upper and lower parts move both the ſame way, either upwards or downwards, and is called *Moto retto*. The ſecond is when in comparing the upper with the lower part, the one aſcends while the other deſcends, or *è contra*, and hence called *Moto contrario*. The laſt is when one of the parts holds out, or continues a ſound, while the other riſes or falls on any note whatſoever; and this is called *Moto obliquo*. Vid. *Broſſ.* Muſ. Dict. in voc.

MOTIVE is ſometimes applied to that faculty of the human mind, by which we purſue good and avoid evil. Thus Hobbes diſtinguiſhes the faculties of the mind into two ſorts, the *cognitive*, and *motive*. Human Nat. p. 4. edit. 1651. See the article COGNITIVE.

MOTOS, (*Cycl.*) in the materia medica of the antients, a name given by Galen and others to a kind of Caſſia bark, the beſt and fineſt that has been uſed at any time. The antients were very fond of this drug, and ranged it according to its different goodneſs into ſeveral ſorts.

MOUCHEROLLE, in zoology, the name of a ſmall bird of the ſize of the ſparrow, and of the ſame colour, but longer bodied; its wings are of a duſkier colour than the reſt of its body; and its head is variegated with very ſmall blackiſh ſpots. Its throat and belly are white, but the throat and the ſides of the breaſt and belly have a faint reddiſhneſs; the beak is black, ſtrait and ridged, ſo as to appear triangular. It feeds on flies and other inſects, and is common in gardens and orchards in many parts of England, though it has no Engliſh name. It is confounded by the common people with the common white throat, but differs from it in that its tail is all of one colour, whereas the white-throat's is variegated. It ſomewhat reſembles alſo the *beccifago*, or petty-chaps, but differs from it in having no greeniſh colour, and in its bill being ridged and triangular. *Ray*'s Ornithol. p. 159. See the article BECCIFAGO.

MOVING *Force.* See the articles FORCE, and VIS *Viva.*

MOULD (*Cycl.*)—MOULDS, in natural hiſtory, are defined to be foſſile bodies compoſed of diſſimilar particles of a looſe ſoft texture, ſomewhat ductile while moiſt, compoſed of argilaceous particles ſeparated by ſand or the gritt of ſtone, and uſually found mixed with the putrified remains of vegetable and animal ſubſtances.

Of this claſs of bodies there are two genera: 1. The thruptomichthes or *Moulds* of a lax friable texture. And, 2. The gloromichthes, which are of a more tough and viſcid texture. *Hill*'s Hiſt. of Foſſ. For the ſeveral ſpecies of vegetable *Moulds*, ſee the articles THRUPTOMICHTHES, and GLOROMICHTHES.

The goodneſs of *Mould*, for the gardeners purpoſes, is known by the ſight, ſmell, and touch.

Thoſe *Moulds* are accounted beſt which are of a bright brown or hazily colour. This is always the colour of the beſt loams, and other natural earths; and this is judged the better, if the earth cut tolerably eaſily, and does not ſtick and cling to the ſpade, but is light, friable, and falls in ſmall clods; and is ſuch as naturally neither chaps and cracks in dry weather, nor turns to mortar in wet. Next to theſe the dark grey and ruſſet *Moulds* are accounted beſt; and the worſt of all are the light and dark aſh-colour; theſe are uſually found on heaths and commons. The clear tawny *Mould* is neither by any means to be preferred; but that of a yellowiſh red is accounted the worſt of all; this is commonly found in wild and waſte places, and ſeldom produces any thing naturally but furz and fern. *Miller*'s Gardeners Dict.

All that lands give us to judge of them by from the ſmell, is, that the beſt after rain, and after digging up, emit a good and pleaſing ſcent: But by the touch they may be judged of with conſiderable accuracy; for by this may be known whether they are too ſandy or too clayey; and whether they be tender, fatty, deterſive, and ſlippery; or more harſh, gritty, porous and friable. What we are to judge beſt by the touch, is the middle nature between the extremes on either ſide, ſuch as will eaſily diſſolve and break, and being made of a juſt proportion of ſand and clay, will not ſtick to the ſpade or fingers after every light ſhower of rain.

To analize *Mould* by means of water, waſh it thoroughly in warm water in large quantities, and filtrate the liquor. Evaporate this to a conſiderable degree of concentration, and it is manifeſtly of a ſaline taſte, but making no alteration in ſyrup of violets; therefore the ſalt it contains is neither acid nor alkaline, but neutral. This analyſis purſued farther, the particles

cles may be disunited and kept separate, and will be found to be a large proportion of sand, a quantity of a light mud, capable of remaining a long time suspended in water, a heavier mud sinking immediately in water. By an analysis of any particular *Mould* by this means, we may find its true constituent particles, and be able to mix up and compound a similar one for the growth of any peculiar plant it produces: But plants have the assistance of heat as well as moisture, in the draining their juices from the earth; therefore it may not be improper to try the effect of fire on the same subject. The common garden *Mould* distilled in a retort in a naked fire, managed in its various degrees, affords a water, and oil and spirit like those yielded by animal subjects, and possibly arising from some extraneous particles mixed with the earth, and a dry *caput mortuum*, or indolent earth remains in the retort.

The particles of animal, vegetable, and mineral substances, floating in the atmosphere, and thence precipitated on the earth, may give some of the properties to garden *Mould*, and those different in different places; as is evident about London, where the *mould* is so impregnated with smoak, precipitated on it from the atmosphere, that it differs much from that of open countries. *Shaw's* Lectures, p. 64.

Moulds *of Coins*, a sort of concave *Moulds* made of clay, having within them the figures and inscriptions of antient Roman coins found in many parts of England, and supposed to have been used for the casting of money.

Mr. Baker having been favoured with a sight of some of these *Moulds* found in Shropshire, bearing the same types and inscriptions with some of the Roman coins, gave an account of them to the Royal Society.

They were found in digging of sand, at a place called Ryton in Shropshire, about a mile from the great Watling-street road. They are all of the size of the Roman denarius, and of little more than the thickness of our halfpenny. They are made of a smooth pot or brick clay, which seems to have been first well cleansed from dirt and sand, and well beat or kneaded, to render it fit for taking a fair impression. There were a great many of them found together, and there are of them not unfrequently found in Yorkshire; but they do not seem to have been met with in any other kingdom, except that some have been said to be once found at Lyons. They have been sometimes found in great numbers joined together side by side, on one flat piece of clay, as if intended for the casting a great number of coins at once; and both these, and all the others that have been found, seem to have been of the emperor Severus. They are sometimes found imprested on both sides, and some have the head of Severus on one side, and some well known reverse of his on the other. They seem plainly to have been intended for the coinage of money, though it is not easy to say in what manner they can have been employed to that purpose, especially those which have impressions on both sides, unless it may be supposed that they coined two pieces at the same time by the help of three *Moulds*, of which this was to be the middle one.

If by disposing these into some sort of iron frame or case, as our letter-founders do the brass *Moulds* for casting their types, the melted metal could be easily poured into them, it would certainly be a very easy method of coining; as such *Moulds* require little time or expence to make, and therefore might be supplied with new ones as often as they happen to break.

These *Moulds* seem to have been burnt or baked sufficiently to make them hard; but not so as to render them porous like our bricks, whereby they would have lost their smooth and even surface, which in these is plainly so close, that whatever metal should be formed in them would have no appearance like the sand holes by which counterfeit coins and medals are usually detected.

Mould-*Warp*, a name given by the people in many parts of England to the mole. See the article Talpa.

MOULDER, in brick-making. See the article Brick-*Making*.

MOUNT (*Cycl.*)—Mount-*Egg*. In the tin-works, after that tin from the burnt ore is melted down, and re-melted, there will sometimes remain a different slug in the bottom of the float; this they call *Mount-egg*; and though of a tin colour, yet is of an iron nature, as hath been found by applying a magnet to it.

MOUNTAIN (*Cycl.*)—The origin of *Mountains* seems to have been from explosions by means of subterranean fires; and it is very probable that they have all vast hollows beneath them; that this might have been the means used at the creation, to make the dry land appear, is no way dissonant to reason, since history proves, that fires have raged in subterranean caverns under the seas, and there is no natural impossibility in fire's subsisting in such caverns, even when the earth was all over covered with water, as at the first creation.

Mountains appear, to many, defects and blemishes in the earth; but they are truly of the utmost use and necessity to the well-being both of man and other animals. Many creatures cannot live but in particular situations, and even the tops of the highest and the coldest *Mountains* are the only places where some creatures as well birds as quadrupeds, will live; of this kind are the ibex and chamois among beasts, and the lagopus among birds.

The *Mountains* alone are able to furnish man with the several metals of so many uses in life; for if these were produced in level ground, it seems very evident that no art could ever keep the mines dry, by which we should get at them; nor could we have springs and fountains, but for the advantage of the height of hills. This seems indeed to be the great design of *mountains*, that their ridges being placed through the midst of continents, might serve to distil fresh water for the use of man and beast; and their heights to give a descent to those streams to run gently down, and be of more benefit to the creation. Thus the more we consider nature, the more we must admire its works; and what seems defect or blemish in them, on a slight view, often proves, on more just observation, a great benefit and beauty. *Ray's* Physico-Theological Discourse, c. 3.

The difficulty of breathing at the tops of high *Mountains* is a thing so plainly felt, that none who has ever been in the way of making the experiment, but is well convinced of the certainty of the fact. Acosta describes what he felt on the tops of the high *Mountains* of Pariacaca very judiciously.

The *Mountains* of Armenia, and particularly that on which Noah's ark is supposed to have rested, have been also made famous by the like accounts; though the snows that lie on the tops of these *Mountains* make it impracticable to ascend their tops; the people who climb as high as they can, always find that they breathe with more difficulty, and are compelled to fetch their breath oftener than when on the plains; and on travellers complaining of this, their guides always tell them, that it is a known thing, and is what every body suffers there.

The *Mountains* in Languedoc and the Pyreneans have the same effect. People of curiosity have sometimes remained hours on the summit of these mountains, and always found the same sort of difficulty in breathing; but it is possible that this may be owing to the exhalations of certain steams from the earth in these places, less loaded with a weight of air than below; and this appears the more probable, as in going up the mountain Teneriffe, if many people are in company, and ascend different ways, some usually bear it better than others; and the very complexions of some are turned yellow by the exhalations which are very plainly perceived by their smell and sharpness, while others who ascend to the same height by different tracts, escape.

The most remarkable *Mountain* in the world in shape, is that called the *needle Mountain*, or the *inaccessible Mountain*, in Dauphiny.

This is a vast hill, placed as it were bottom upwards, or set on its summit on the earth with its broad base elevated in the air; it is but about a thousand paces in circumference at the bottom, and is above two thousand at the top. On the center of the plain at the top there stands another small and very narrow, but very high hill.

It obtained the name of the *needle* as it got the other, by its being supposed impracticable to the ascent of any one, by reason of its projecting so greatly outwards. Some hardy persons however once ventured to climb it, and found at the top a number of the chamois, animals by no means qualified for climbing, and which doubtless had never either ascended or descended the *Mountain*, and which must be supposed to have bred there for many ages, though it be very difficult to account for their first getting to the place. Hist. Acad. Par. 1700.

Chains of Mountains, a term used by geographers to express those continuations of *Mountains* which run in strait ridges along whole countries, and appear disposed in uninterrupted orders wherever they are found. Kircher labours to prove, that these chains are annular, and reach absolutely round the globe of the earth, encompassing it from north to south, and thence to the north again; and in the same manner from east to west, and from thence to the east again; their course only disappearing, by the wise providence of nature, in the bottoms of the sea, that the immense body of waters treasured there might have its motion free and unimpeded in its channel, but appearing again in the same line in every the smallest island that shews itself in the way of their strait course; from the country where the last link of the chain was seen, to that where their first link appears again. He says that these vast hills of earth and stone, serve not only to strengthen and support the fabric of this vast globe of earth, but they have another very great use, not only to man, but to all animals, and even vegetables; which is, that they are the storehouses where the grand reservoirs of fresh water, so necessary to all life, are treasured up, and from whence it is easily poured down upon the lower parts of the globe. In Europe, the great reservoirs of water, that supply whole countries of immense extent, are placed in that vast chain of *Mountains* called the Alps, from which, as from an inexhaustible store, the vast tracts of fruitful land that lie below them are sufficiently watered.

The *Mountains* which compose this part of the great annular chain running north and south round the globe, are called by three different names; the *Cottiæ*, the *Rhætian hills* with the *Vogesus*, and the *Appennines*; from these are poured out the immense rivers which water this fruitful part of the world, the Danube, the Rhine, the Rhone, the Moselle, and an

almoſt infinite number of others, every one of which, after it has ſupplied the inhabitants of a whole tract of vaſt extent, diſcharges ſo much water hourly into the ſea,, that the mind is aſtoniſhed at the account, and would wonder whence only one of them could be ſupplied. Theſe rivers, and a multitude of other ſmaller ones, and beſide theſe a great number of lakes of vaſt extent are all ſupplied by the hydrophylacia or reſervoirs of water treaſured up in the boſoms of theſe hills, and could not have performed their office of watering theſe extenſive countries, had thoſe reſervoirs been placed any where except in ſuch a lofty ſituation in theſe *Mountains*. *Kircher*'s Mund. Subter.

The Alps, though they all ſupply more or leſs of this profuſion of water, yet they are not all equally hollowed for the reception of it, and conſequently do not all contain ſupplies for an equal tract of land; this is provided for by nature by a vaſt number of other ſmaller *Mountains*, which in ſeveral parts of the countries through which this chain paſſes, run from its ſides like leſſer knots, and extend over ſome ſmaller or greater part of the country.

Theſe are a ſort of auxiliary ſupplies, and ſerve for many countries in the place of the original heads; but the rivers propagated from theſe, though ſufficient for the occaſions of the inhabitants of the lower country, yet do not diſcharge thoſe vaſt quantities of waſte water into the ſea that thoſe which derive their origin from the greater *Mountains* do. The Noric *Mountains* in Germany, the Vogeſus, many mountains in Dauphiny, and thoſe in Italy, which run from the ſides of that long chain, which reaches like a ſpine all along that country, are all of this kind, and all leave this benefit to the lower countries. The Pyrenean and Carpathian *Mountains* alſo yield a vaſt number of rivers from their ſides; and the rivers of Spain, of Poland, and of Hungary, all have evidently the ſame origin from theſe high-ſeated reſervoirs, in the chains of *Mountains* which paſs through them. The countries where extended plains are found for vaſt tracts uninterrupted by any of the links or knots of theſe vaſt chains of *Mountains*, are the only places where thirſt and drought are the deſtruction both of animals and plants; and, in general, that country which has moſt and higheſt *Mountains*, is the moſt plentifully, moſt regularly, and moſt conſtantly watered by ſmaller as well as larger ſtreams.

The diſpoſition of *Mountains* on the ſurface of the globe ſeems more regular than is generally ſuppoſed by thoſe who ſee but a few of them in particular countries at a time; they are diſpoſed in reality in ranges or chains, reaching to vaſt extents, and in ſome from pole to pole from north to ſouth.

One grand chain of *Mountains* reaches from Iceland through Scotland, England, and Germany, with a ſtrait courſe to the Alps, which are as it were a vaſt knot in this chain, more cloſely diſpoſed, and more eminent than the others.

Theſe are ſucceeded in the ſame ſeries by the Appennines, which run through the whole kingdom of Italy in the manner of the ſpine of the back in animals, and are continued on in the ſame ſeries by thoſe of Sicily; and from theſe the ſame chain is carried on to Africa, and continues in what are called the *Mountains of the Moon*. From hence another vaſt knot or link of this extenſive chain is carried on to the utmoſt part of Africa, and terminates, as to our view, at the Cape of Good Hope; and there is no reaſon to doubt but that the chain is continued in the oppoſite land, and ſo on to the utmoſt limits of the ſouthern pole. From hence the ſame ſeries makes its way again, and beginning anew as it were from the ſouth pole, is carried on through the little known ſouthern regions to the Magellanic Streights. Here the famous Andes *Mountains* of South America take it up, and along this vaſt tract it is carried through this part of the new world into North America, and thence to the northern pole again, terminating where it began, or joining the other part of the chain where we took up the beginning of our account; ſo that the whole ſeries making a vaſt belt or circle round the globe, has no beginning nor end, but in our imagination, or in our ignorance of the parts of the world through which it is carried in the ſame regularity as in thoſe countries whither commerce has led us, and where maps have ſheen them.

Another vaſt chain of *Mountains* running with the ſame regularity, and in the ſame manner forming a belt round the whole globe of the earth, cuts this at right angles, and is continued in its courſe. This goes through Tartary from a beginning far beyond our reſearches up behind that vaſt country, and continuing itſelf through the middle of Scythia, forms a ſeries that appears in the Eaſt Indies, running along the middle of that vaſt region to Cape Comorin; here the chain dips into the ſea; but if its courſe is exactly marked, it will be found to be continued in the ſame rout through the iſland of Ceylon; hence it is carried under water to its oppoſite point on the limits of the earth, and hence through ſeas and lands not yet known to us, is carried on to the place in the back of Tartary, and from which we have begun the account. We have but very ſmall proofs indeed of its continuation through a vaſt tract of this its courſe; but we are to accuſe for this defect not nature in her diſpoſal, but our own ignorance, whatever little we do know plainly pointing out, that the chain is continued in the ſame regular manner as the other, and placed exactly at right angles with it.

As the continual flux and reflux of that vaſt body of ſeas from the eaſt weſtward, might by its force do ſome miſchief to the compages of the earth, provident nature has contrived for the ſtrengthening the great frame of this globe, certain tranſverſe chains or belts of mountains, which are ſo diſpoſed as to ſtrengthen and keep together the whole machine in the moſt ſtrong and laſting manner. One ſeries of theſe runs directly from the eaſt weſtward from the utmoſt limits of the Chineſe empire, through that whole vaſt country, and where theſe are ſtopped by the boundaries of that country, they are continued through the weſt of Scythia, India, and the Caſpian Sea, America, Aſia Minor, Macedonia, and to the Rhætian *Mountains*, which carry on the chain to the *Mountains* of Narbon, Gaul, and theſe to the Pyreneans; and theſe are carried on weſtward in the ſame direct chain, ſo far as we are able to trace them, and apparently run on toward the point from which the account began, ſo as to form as regular a circle as the others, were every link of it expoſed to our ſight, by our knowledge of the regions through which it paſſes, and many of which are yet left to future diſcoveries.

The haſty judgers of this ſyſtem may ſuppoſe, that it wants due weight, becauſe the chains of *Mountains* here deſcribed do not appear to be regularly carried on through the bottom of the ſea from the laſt link on one land to the firſt on the oppoſite land to it; but the whole chain ſeems broken abruptly at either promontory, and only to be renewed, not continued, at the other; but it is very probable, that though not ſo evident to our eyes, theſe chains of *Mountains* are continued under the bottoms of the deepeſt ſeas in the ſame regular manner as on the openeſt land, though their heads do not appear above the ſurface of the water; but are only ſeen at thoſe places where the ſcattered iſlands happen in their courſe, till they arrive at the main land again. This diſpoſition is not to be ſuppoſed owing to chance or irregularity, but appears contrived by the wiſdom of the great Creator.

The vaſt body of ſeas that ſurrounds the globe with its neceſſary and perpetual flux, required a clear and free bed to roll its immenſe congeries of waters in; and the tops of the *Mountains* appear to have been diſcontinued in the courſe of this fluid, that it might have a free channel, and no ſtops or hindrances in its courſe, to ſpread its waters over the whole earth.

Cock of the MOUNTAIN, *Urogallus*, in zoology. See the article UROGALLUS.

MOURNING, (*Cycl.*) among the antients, was expreſſed various ways, as by tearing their clothes, by wearing ſackcloth, laying aſide crowns; and every other mark of joy. Plutarch, in his life of Cato, relates, that from the time of his leaving the city with Pompey, he neither ſhaved his head, nor, as uſual, wore the crown or garland. Sometimes public grief was teſtified by a general faſt. *Hofm.* Lex. in voc. *Mœſtitia*. See the article FASTING.

Among the Romans a year of *Mourning* was ordained by law for women who had loſt their huſbands.

In public *Mournings* at Rome the ſhops were ſhut up, the women laid aſide all their ornaments, the ſenators their laticlavian robes, and the conſuls ſat in a lower ſeat than uſual. See *Pitiſc.* in voc.

The antients had a remarkable way of *Mourning* for ſoldiers, ſlain in battle. The whole army attended the funeral ſolemnities with their arms turned upſide down, it being cuſtomary for *Mourners*, in moſt of their actions, to behave themſelves in a manner contrary to what was uſual at other times. In thoſe places where it was the faſhion to wear long hair, *Mourners* were ſhaved; and where others ſhaved, *Mourners* wore long hair. Their conjecture therefore is frivolous, who imagine that the ſoldiers turned the heads of their ſhields downwards, leſt the gods, whoſe images were engraven upon them, ſhould be polluted with the ſight of a corpſe; ſince not the gods only, but any other figures, were frequently repreſented on ſhields; nor did the few only near the corpſe, but the whole company held their ſhields in the ſame poſition: Not to mention that other arms were alſo pointed downwards. *Potter*, Archæol. Græc. T. 2. p. 103.

The *Mournings* of the Eaſtern nations of Indians are much more cloſely followed, though of much ſhorter duration than ours. After the death of a near relation they *mourn* fifteen days, during which time they eat nothing but rice and water. They are not to chew betle, or to uſe the common waſhings in this time; but they are to do acts of charity, ſuch as diſtributing food to the poor; and prayers are ſaid, intreating the Almighty to forgive the ſins of the dead perſon, and to aſſign him a good place in the other world. On the ſixteenth day, that is the day after the finiſhing of the time of *Mourning*, they make a ſolemn feaſt according to their abilities, and invite to it all their friends and neighbours. After this they annually, on this day, give food to the poor, and renew their prayers for the happineſs of the dead perſon. Phil. Tranſ. N°. 243.

MOUSE, *Mus*, in zoology. See the article MUS.

Sable-MOUSE. See the article SABLE.

MOUSE-*Ear*, in botany. See the article MYOSOTIS.

MOUSE-*Deer*. See the article MOOSE-*Deer*.

MOUTH (*Cycl.*)—Whether the *Mouth* of a fœtus be neceſ-

fary for its nutrition, has been controverted. The learned Mr. Monro is of opinion it is not: See his reafons, and his anfwers to what has been advanced by many learned men in favour of the contrary opinion, in the Med. Eff. Edinb. Vol. 2. Art. 9. or the Abridgment, Vol. 1. p. 305.

Mr. Monro obferves farther, that the opening of the *Mouth* does not only depend on the motion of the lower jaw downwards, but alfo on the fuperior jaw being raifed up by the mufcles, which extend the head back. He fays any one may convince himfelf of the truth of this, by putting the blade of a knife oppofite to the conjoined edges of the teeth, when the *Mouth* is fhut; and the knife being held unmoved while the *Mouth* is opened, he may, by the help of a mirror, fee the upper teeth raifed remarkably at every aperture he performs. Medic. Eff. Edinb. vol. 1. art. 11.

In the fifh kinds the *Mouth* is very different in the feveral genera and fpecies in its fituation, figure, and proportion, and is by the beft naturalifts made a mark of diftinction among them. In regard to place or fituation, it is, 1. in fome placed in the front or tip of the head; and in this cafe both the jaws are fometimes of the fame length; fometimes the one is confiderably longer than the other. Examples of this fituation occur in moft fifhes. 2. In fome the *Mouth* is placed in the lower or under part of the head under the fnout. Examples of this we have in the ray-fifhes, the fquatina, the petromyza, &c. 3. In fome fifhes it is placed tranfverfely to the body, that is, the opening of the *Mouth* cuts the fite of the back and belly at right angles: But 4. In others it is oblique. The generality of fifhes give us inftances of the firft fituation; and the pleuronecti in general give us examples of the laft.

As to figure, there are alfo very many differences. When the *Mouth* is opened, it is in fome, 1. of an oblong, round, or roundifh fquare fhape; this we fee inftances of in the cyprini, &c. 2. In others it is oblong and wide; of this we fee inftances in moft fifh. 3. It is fpherical, as in the petromyzæ. Thefe are the general diftinctions; but befide thefe there are many leffer diftinctions, which are only degrees of thefe.

The proportion of the *Mouth* to the head is alfo very various; 1. In fome it is much fmaller than the breadth of the head; of this we fee examples in the cyprini, cobites, pleuronecti, and many others. 2. In fome it is equal to the width of the head, or very nearly fo, as in the cotti, filuri, &c. *Artedi*, Ichthyol.

MOUTON *d'Or*, an old French coin. See the article AGNEL.

MOXA (*Cycl.*)—The antient phyficians ufed flax, as the people of the eaftern nations now do their *Moxa* for cauterizing in certain parts of the body. The method of ufing the *Moxa* is this: A fmall cone of the down or *Moxa* is to be made up of about a thumb's breadth long, much after the manner they are for a fuffitus. The bafis of this cone is to be ftuck upon the part with a mucilage of gum arabic, and its top is then to be fet on fire by a candle or burning coal. By this means the whole cone will be gradually confumed, and the part by degrees cauterized. This is ufed in cafes of the gout; and if the pain does not ceafe on the firft operation, it is to be repeated till it does. *Heifter*'s Surgery, p. 319.

MOYNAU, in fortification. See the article MOINEAU.

MUCILAGINOUS *Glands* (*Cycl.*)—The rough unequal depreffion at the bottom of the cotyloide cavity of the offa innominata is filled by a broad flat *mucilaginous* gland, bordered with a fatty fubftance, and covered with a fine membrane. The *mucilaginous* glands of the bones of the leg lie in fmall fpaces, depreffions, and fuperficial notches, near the edges of the cartilages of each joint, and are all covered by the capfular ligaments. In the bones of the foot thefe glands anfwer in number and figure to the depreffions between the *cartilaginous* edges and ligaments.

In the articulations of the fternum, vertebræ, and ribs, the *mucilaginous* glands are very fmall; but they are accompanied by many fatty moleculæ lying round each joint. The inner furface of the ligamentary tube which lines the bony canal of the fpine, is lubricated alfo by an oily or adipofe fubftance. And the true *mucilaginous* glands of the occipital and maxillary articulations in the bones of the head, are all proportioned to the joints to which they belong, and lie between the capfular ligaments and the circumferences of the cartilages. *Winflow*'s Anatomy, p. 125, feq.

MUCILAGO, in botany, a name under which Micheli has comprized fome fpecies of that kind of fungus called *mucor*, confifting of fmall bladders, or veficles with feeds affixed to filaments on the inner part. See the article MUCOR.

MUCOCARNEOUS, an epithet ufed by authors for a fort of abfceffes, which are partly made up of flefh and partly of a thick mucous matter.

MUCOR, in botany, a name given by Micheli, and continued by Linnæus, to a genus of mufhrooms, often comprized by authors among the moffes, and called by the fame Micheli under the fmall varieties of fome of the fpecies, *mucilago* and *lycogala*. Their characters are thefe: They are fungufes confifting of roundifh little bladders, in which are found numerous feeds affixed to hair-like receptacles, placed all over the infide of the bladders.

MUCOSA, in ichthyology, a name given by the Italians to a fpecies of the ray-fifh, called by the old authors, *leioraia*, and *bos marinus*; and by the latter authors, *raja oxyrynchus* and *læviraia*. It is diftinguifhed by Artedi by the name of the variegated ray, with ten prickly tubercles on the middle of the back. See the article RAJA.

MUCOUS (*Cycl.*)—MUCOUS *Fevers*, a term ufed by medical writers to exprefs thofe fevers in which nature is endeavouring to rid herfelf of an abundance of pituitous, mucous, and ferous matter. The catarrhal fevers of all forts are expreffed under this denomination. *Junker*'s Confp. Med. p. 252. See the article FEVER.

MUCRONATED, whatever ends or terminates in a point, like that of a fword, &c.

MUCU, in zoology, the name of a Brafilian fifh of the lamprey kind. It is long and flender; its head is pointed; its eyes black and fmall; and its mouth very fmall; and it has no fins. It is brown all over, only of a dufkier colour on the back than on the belly, and has a number of obliquely tranfverfe lines on the fides, which are black. It is an eatable fifh, and is caught in lakes in Brafil. *Marggrave*, Hift. Braf. p. 96.

MUCUS (*Cycl.*)—MUCUS *of Fifhes*. The bodies of moft of the fifhes called *alepidotes* by authors, from their having either no fcales at all, or only a few fmall ones, are covered in the place of fcales with this *Mucus*. It is a tough and thick vifcous liquor, and fticks firmly to the body, defending the fkin from injuries from ftones, and the like. It is fecreted from certain glands placed about the head, and on moft parts of the body, but particularly in the linea lateralis. *Artedi* Ichthyology.

MUDD, in ichthyology, a name given by the Swedes to the fifh called by Schonefeldt and others, *aphua* or *aphya*.

It is a fpecies of the cyprinus, according to Artedi, and is diftinguifhed by that author by the name of the *red-eyed two-inch cyprinus*, with nine bones in the pinna ani. See the article CYPRINUS.

MUERDEM, among the Turks, an officer belonging to their mofques, who with his voice calls the people to prayers; thereby fupplying the want of bells, which the Mahometans will not ufe. *Hofm.* Lex. in voc. See the aiticles BELL, and MOSQUE, *Cycl.*

MUFFLE, in metallurgy, is an arched cover, refifting the ftrongeft fire, and made to be placed over coppels and tefts in the operations of affaying, to preferve them from the falling of coals or afhes into them; though at the fame time of fuch a form, as not to hinder the action of the air and fire on the metal, nor prevent the infpection of the affayer.

The *Muffles* may be made of any form, fo they have thefe conditions; but thofe ufed with coppels are commonly made femi-cylindrical, or when greater veffels are employed, in form of a hollow hemifphere.

The *Muffle* muft have apertures, that the affayer may look in, and the fore part of it muft be always quite open, that the air may act better in conjunction with the fire, and be inceffantly renewed; for without this, fcarce any fumes are to be produced, and without thefe, the vitrification of lead is fcarce practicable; for when the air is once filled with a certain quantity of vapours, it fcarce admits any more afterwards; and for this reafon a conftant fucceffion of frefh air is neceffary. The apertures in the *Muffle* ferve alfo for the regimen of the fire; for the cold air rufhing into the larger opening before, cools the bodies in the veffel; but if fome coals are put in it, and its aperture before be then fhut with a door fitted to it, the fire will be increafed to the higheft degree, much more quickly than it can be by the breathing-holes of the furnace. Another ufe of thefe apertures is alfo, that the arfenical vapours of lead and antimony paffing through the holes in the back part of the *Muffle*, may not be offenfive to the affayer, who ftands before it.

As to the height, length, and depth of the *Muffles*, thefe muft be proportioned to the fize and number of the veffels they are intended to cover; and care muft be taken in this, that all parts of the inner furface of thofe veffels muft be in the reach of the affayer's eye. The moft frequent fize of the *Muffle* however is four inches high, fix or eight inches long, and four or fix inches broad. The fegments cut off at the bafes, for the leffer holes muft be of fuch a proportioned height, that the leaft veffels put under it, may not be in the way of coals or afhes falling into them, for that always hinders the vitrification of lead, and the deftruction of the other metals and femi-metals, and will fometimes entirely reduce them again when already deftroyed; and the fcoriæ, foftened by afhes, foften and retard the operation.

Wooden moulds of a proper fhape, are moft convenient for the making thefe *Muffles* in, and the matter for making them of is the fame with that of the German clay tefts; that is, either a pure native clay, of a condition to bear the fire, which will be known upon the trial; or fuch clay, hardened by a mixture of the powder of ftones: And in order to the forming of thefe, the mafs muft be made tolerably foft and pliant. Knead a fufficient quantity of this mafs with your hands upon a flat ftone; fpread it out evenly into a thin cake or plate, fomewhat longer and broader than you intend the *Muffle* to be made; and fo thick, that two or more thin plates or lamina, of about two lines thick each, may be cut off from it. This is eafily done by rolling the mafs on the ftone with

a rolling-pin, ſtrewed over lightly with aſhes, or powder of chalk.

When the cake is thus rolled out, with a thin, fine, and perfectly ſtrait braſs wire cut off from the cake one thin plate; this muſt be done with great caution, left it ſhould break; take this up, and rubbing it over with oil or fat, lay it over the mould; then cut out a ſemicircular piece from the maſs, of the ſame thickneſs with the former, and with this cover the back plane, or farther end of the mould, joining the edges of this plate to thoſe of the former, cloſely and perfectly, by wetting them well with water.

Next cut off from the cake another thin plate, to be the bottom of the *Muffle*; this may be either left looſe for the *Muffle* to be placed on it occaſionally, or the bottom edges of the already formed *Muffle* may be joined to it all round by means of water, as the back was before joined to the arched part of the *Muffle*. But whether it be intended that the bottom ſhall be thus fixed on, or left looſe, it muſt be half an inch broader every way than the bottom of the *Muffle*, that this may ſtand the more ſure and firm upon its baſis.

When the *Muffle* is thus made, wet your hand, and rub it carefully all over, that the ſmall and perhaps inviſible cracks and chinks in the plates may be cloſely joined, and the whole matter of it applied perfectly cloſe to the ſurface of the mould.

When the *Muffle* has been ſome time expoſed to the air, and is ſomewhat dried, and hardened on the mould, cut out two or three hemiſpherical pieces on each ſide, to make the holes before deſcribed, at the baſis and back, and then draw away the mould from within it; for if the *Muffle* is ſuffered to dry perfectly on the mould, it always cracks. When the whole is perfectly dry, let it be baked in a potter's kiln, or in the aſſayers oven; but without great care in the latter method, and lighting the fire at top firſt, it is apt to crack; ſo that the potters kiln, where at hand, is much the better way of baking it. See Tab. of Chemiſtry, N°. 1. 2.

If there be adapted to the formerly deſcribed convex mould, another concave one nearly fitting it, only leaving room for the thickneſs of the *Muffle* between, and the clay be placed between them, and formed by this means into its exact ſhape, by a ſtrong and every way equal preſſure, this will make *Muffles* not only with much leſs trouble, but they will be much ſtronger, leſs apt to crack, and more capable of reſiſting the fire, than thoſe made by the hand in the other way.

The only cautions neceſſary for the making theſe, are, that the clay be a little drier than when it is to be worked by the hand; that the ſides, both of the inner or convex mould, and of the outer concave one, be thoroughly oiled or greaſed, and the preſſure on the ſurface of the outer or concave mould, be as ſtrong and as equal as may be. There is no clay better for the making theſe *Muffles* than the *Windſor loam*, an earth well known among the chemiſts and glaſsmen, and always to be ſold in London; and the rubbing the inſides of the mould with black lead in fine powder, very well ſupplies the place of greaſing them, to prevent the matter from ſticking to them.

Theſe are the *Muffles* ordinarily uſed in aſſaying; but when very large teſts are to be covered, they uſe large ſpheroidal *Muffles*, made of caſt iron, or ſometimes of the ſame clay, and wrought in the ſame manner, only made upon proportionably larger moulds. The clay is uſually, for theſe large ones only, laid in a lump on the top of the mould, and with wet hands ſpread all over it to the bottom, and by this means a *Muffle* is made with little trouble. *Cramer's* Art Aſſ. p. 62.

MUGGENT, in zoology, the name of a ſpecies of freſh water wild duck, called by many authors the *muſcaria*, from its catching flies that play on the ſurface of the waters.

It is about the ſize of the common tame duck. The beak is ſhort and broad, and is of a ſaffron colour. It is all over of a mottled colour, like that of the partridge, made up of black, white, brown and grey, ſo oddly mixed together, as to ſhew neither ſeparate. The crown of the head is black, and the feet are yellow. *Geſner* de Avib.

Mr. Ray ſuſpects this not to be different from our common wild duck.

MUGWORT, *Artemiſia*, in botany, the name of a genus of plants, the characters of which are theſe: The flower is of the floſculous kind, being compoſed of ſeveral floſcules, divided into many ſegments at their ends, ſtanding on the embryo ſeeds, and contained in a ſcaly cup. Among the flowers there alſo appear many naked embryos, which terminate in a fine ſmall filament, bifid at the end. Theſe, as well as the embryos of the flowers, finally become ſeeds, in ſhape reſembling thoſe of wormwood.

The ſpecies of *Artemiſia*, enumerated by Mr. Tournefort, are theſe: 1. The common *Artemiſia*, with a purple ſtalk, and purple flowers. 2. The larger *Artemiſia*, with greeniſh-white ſtalks. 3. The *Artemiſia* with leaves variegated with yellow. 4. The red ſea *Artemiſia*. *Tourn.* Inſt. p. 460.

Mugwort has long been famous as an uterine and antiſpaſmodic, and a medicine of great efficacy in all diſeaſes of the nerves. It is evidently aperient and abſtergent; it promotes the menſes, and cleanſes the womb. It is given in decoction, or much more agreeably in a light infuſion, in the manner of tea. The midwives uſe it alſo externally, boiling it, and applying it to the belly, to promote the menſtrual diſcharges, or the expulſion of the ſecundines. It is by ſome much recommended as a cure for the *ſciatica*; and it is to be taken for this purpoſe, either in powder, two drams for a doſe, or the expreſſed juice drank an ounce or two twice a day for ſome months. There uſed to be a diſtilled water, a ſyrup, a conſerve, and an extract of *Mugwort* in the ſhops, and the ſalt was made as that of wormwood; but at preſent theſe are diſuſed, and the dried herb only is kept there, as an ingredient in ſome of the compound waters. *Hill*, Hiſt. Mat. Med. p. 342, ſeq.

MUGIL, the *Mullet*, in ſome degree reſembles the dace or dare in ſhape. The noſe is ſharp; the belly a little bowed; the head plain and flatted. Its ſcales are very large, and cover not only the body, but the membranes of the gills, and a great part of the head. The back is of a duſky bluiſh or greeniſh brown; the belly white, and the ſides are variegated with longitudinal black and white lines running from the head to the tail. It has no teeth; but the tongue is ſomewhat rough. It is ſuppoſed to feed wholly on weeds, and the like; and ſeems indeed to eat no fiſh. It is moſt frequently caught at ſea; but at times comes up into rivers. *Willughby's* Hiſt. Piſc. p. 275.

The *Mullet* is a very well taſted fiſh; and of its ſpawn is made what we call *botargo*. See the article BOTARGO.

Rondeletius, and other authors, have deſcribed three or four different ſpecies of *Mugil*; but they ſeem rather varieties of the ſame fiſh, owing to age, place, and other accidents.

In the Artedian ſyſtem of ichthyology, the characters of the *Mugil* are theſe: The branchioſtege membrane on each ſide contains ſix crooked bones; the upper one being the broadeſt, and being hid under the covering of the gills, ſo that only five are diſcernible. The ſcales are large, and they cover the head; and the opercula of the gills, as well as the body of the fiſh. The head is of a depreſſed figure in its anterior part; and the body is oblong and compreſſed. According to theſe diſtinctions, there is only one known ſpecies of *Mugil*; this is the *Mugil* of Ovid and the antients. It reſembles the thymallus in its external figure. Its jaws are tender and thin, and have no teeth in them. The tail is forked. *Artedi* Gen. Piſc. p. 26.

MUGIL *Alatus*, the *winged Mullet*, a name given by ſome authors to the *hirundo piſcis*, or ſwallow-fiſh, as, excepting its wing-fins, it very much reſembles the *Mullet* in ſhape. *Geſner* de Piſc. See the article HIRUNDO *Piſcis*.

MUGIL *Niger*, the *black Mullet*, a name given by authors to a fiſh of the *Mullet* kind, but all over black, more uſually known by the name of the *portius piſcis*. *Ray's* Ichthyol. p. 276.

MULÆ, a word uſed by ſome medical writers to expreſs puſtules on the ſkin, which are owing to extreme heats, or to cold.

MULA *Herba*, in botany, a name uſed by ſome for the ceterach, or ſmooth ſpleenwort. *Ger.* Emac. Ind. 2.

MULBERRY, *Morus*, in botany, &c. See the article MORUS.

The common *Mulberry*-tree is to be propagated either by ſowing the ſeeds, or by laying down the tender branches, which in two years will be well rooted, and may be cut off from the tree, and tranſplanted into the places where they are to remain. But thoſe plants which are propagated from ſeeds, are uſually the moſt vigorous, and grow the moſt regularly, and with the ſtraiter ſtems; but then there is a great diſadvantage attending this propagation, which is, that the trees are frequently altogether male, producing only catkins, and no fruit; ſo that it is better to do it by layers from a tree, which is known to produce plenty of good fruit; the ſtraiteſt ſhoots ſhould be always choſen for layers; and when they are tranſplanted, they ſhould be tied up to ſtakes to keep them ſtrait. This tree ſhould not be often pruned; but only ſuch branches are to be cut off as croſs and bruiſe one another.

The *Mulberry*-tree thrives beſt in a light ſoil, which ſhould not be too wet, nor over dry; and it ſhould always have an open expoſure; for if planted too near trees or buildings, ſo as to be ſhaded thereby, the fruit ſeldoms ripens well; though it will be to great advantage to have them defended from the weſt and ſouth-weſt winds, by trees or buildings at a diſtance.

The ſoil under the *Mulberry*-tree ſhould always be well dug up every year, and manured, which proves of very great ſervice to the fruit.

The white *Mulberry* is cultivated in France and Italy for the ſake of its leaves, as there is an opinion, that the ſilk-worms ſhould be fed only with theſe; but it is affirmed by perſons who ſeem to know beſt, that the Perſians feed their worms only with the leaves of the black kind.

The trees intended for feeding ſilk-worms ſhould not be ſuffered to grow tall, but kept in a ſort of hedge; and inſtead of pulling off the leaves ſingly, they ſhould be cut off with ſheers together with the young branches; this is not only much ſooner and more eaſily done, but it is leſs injurious to the

the trees. The white sort is propagated either by seeds or layers as the black, and is equally hardy. *Miller's* Gardener's Dict.

MULBERRY-*Cyder*, a name given by the people of Devonshire, and some other parts of England, to a sort of cyder rendered very palatable by an admixture of *Mulberry* juice in the making: They choose for this purpose the ripest and blackest *Mulberries*, and pressing out their juice and mixing it with a full-bodied cyder at the time of the grinding and pressing, giving just so much of it as adds a perceptible flavour. It is very worthy the attention of people who live in other counties, where strong and good cyder is made, that this renders it a sort of wine much more agreeable than any other English liquor, and might be brought into general use, to the great advantage of the dealer. The colour of this liquor resembles that of the brightest red wine, and the flavour of the *Mulberry* never goes off. Phil. Trans. N°. 133.

MULBERRY-*Shell*, a species of *Dolium*. See the article DOLIUM.

MULE (*Cycl.*)—*Mules* are chiefly used in countries where there are rocky and stony ways, as about the Alps and Pyrenees, &c. Great numbers of them are kept in these places; they are usually black, and are strong, well-limbed, and large, being mostly bred out of the fine Spanish mares.

The *Mules* are sometimes fifteen or sixteen hands high, and the best of them are worth forty or fifty pounds a-piece. No creatures are so proper for large burdens, and none so sure footed. They are much stronger for draught than our horses, and are often as thick set as our dray-horses, and will travel several months together, with six or eight hundred weight upon their backs. It is a wonder that these creatures are not more propagated in England, as they are so much hardier and stronger than horses, and are less subject to diseases, and will live and work to twice the age of a horse.

Those that are bred in cold countries, are more hardy and fit for labour than those bred in hot; and those which are light made are fitter for riding than horses, as to the walk and trot; but they are apt to gallop rough, though these do it much less than the short-made ones. *Mortimer's* Husbandry.

They take so much after the mare they are bred from, that they may be procured of any kind, light or strong, as the owner pleases. The general complaint we make against them, is, that they kick, and are stubborn: But this is only owing to our neglect in the breeding them, for they are as gentle as our horses in countries where they are bred with more care.

Mules are of two kinds; the one between the horse and the she-ass, the other between the he-ass and the mare. The first sort are the least valuable. They are commonly very dull, and take after the ass, and are not large; the other breed is therefore what is propagated chiefly in all countries where mules are used. The largest and finest he-ass must be procured for this breed; and in Spain, where *Mules* are greatly esteemed, they will give fifty or sixty pounds for a fine he ass, only to be kept as a stallion. They breed with this creature out of the finest and largest mares they have, giving the ass an advantage of height of ground, and putting the mare into a narrow pit, railed on each side.

Some authors affirm, that in Syria there are a sort of *Mules* which propagate their species; but this is a mistake; for in all the countries where they are common of both kinds, no such thing ever happens.

If the ass designed to be bred on is suckled by a mare, or the mare suckled with an ass, it makes them much more familiar than they would otherwise be; and this may always be done by taking away the colt that belongs to the dam, and putting the other in its place, keeping them in the dark ten days or a fortnight.

MULGRANOC, an English name for a small sea-fish caught in the Cornish and other shores, the *alauda non cristata* of Rondeletius, and the *galeetto* of other authors. *Willughby's* Hist. Pisc. p. 133.

MULIERTY, the being or condition of a *Mulier*, or lawful issue. Co. Litt. 352. *Blount*.

MULLER, (*Cycl.*) in zoology, a name used by some for the fish called in Latin the *Cataphractus*, and in English the mailed fish, or pogge. *Willoughby's* Hist. Pisc. p. 212. See the article CATAPHRACTUS.

MULLET, (*Cycl.*) in zoology, a name by which the people in some counties of England call the *Anas arctica Clusii*. See the article DUCK.

MULLETT, in ichthyology, a name given in England indeterminately to several kinds of fish of different genera; but the proper sense of the word is the same with that of the mugil or cephalus, of the generality of authors; the cephalus of Aristotle and the Greeks; and the cestreus or cestrea of Oppian and others. See the article MUGIL.

MULLUS, in zoology, the name of a fish properly of the cuculus kind, of which there are two species; the one called *Mullus imberbis*, the other *Mullus asper*. The first is a very scarce sea-fish, with a large head, ornamented with several small figures of stars, large eyes, a small mouth of a fine bright red within, and without teeth; the covering of the gills have several prickles pointing toward the tail; the whole body is of a reddish colour, and the gill-fins have near their end some filamentous-fingered appendages. Its belly is white, and there are two rows of pointed bones running from the head to the tail all along the back.

The other, or *Mullus asper*, is a small fish of about the length and thickness of a finger, and of a beautiful red or somewhat purplish colour; and is covered with scales serrated at their extremities, and placed obliquely. *Rondelet.* de Pisc. p. 640.

MULLUS *Barbatus*, in zoology, the name of a fish of the cuculus or the gurnard kind, caught in the Mediterranean, and reckoned an extremely delicate fish for the table. Its usual size is about six or seven inches in length. Its head is flatted and its body considerably thick; and the back flat, not ridged. From the head all the way to the tail, it becomes gradually smaller, so as to resemble an obelisk in figure. Its scales are serrated at the edges, and are easily rubbed off; they are of a brownish olive colour; but the sides, when they are off, look as if tinged with red lead. The eyes stand very high in the head, and it has two very long beards under its chin. It has no teeth in the jaws, and its tail is very forked. *Gesner* de Pisc. p. 285.

MULLUS *Imberbis*, in zoology, the name of a small fish caught in the Mediterranean and Archipelago, and called by many *rex mullorum* and *re de triglia*. Its usual size is about four or five inches in length. It is all over of a reddish hue, and is covered with very large scales. Its belly is also somewhat prominent, by which it is distinguished from all the other mullets. Its eyes are large, its mouth very wide, and its jaws rough like a file. Its tail is forked, and it has no beards. *Willughby's* Hist. Pisc. p. 286.

MULTIBONA, in botany, a name given by some authors to parsley. *Ger.* Emac. Ind. 2.

MULTIFIDUS *Spinæ*, in anatomy, a name given by Albinus to a muscle, the several parts of which he says have been called by several different names by the generality af anatomical writers.

That part of it which is situated in the region of the loins, is called by Vesalius, the *decimus tertius* and *decimus quartus dorsum moventium*, and by some the *tertius dorsi musculus*. That which is situated in the back is called by Vesalius, *decimus quintus* and *decimus sextus dorsum moventium*, and by others, *quintus dorsi musculus*.

That part which is in the neck is called by Vesalius, the *septimus* and *octavus dorsum moventium*, and by many the *quartus cervicis musculus*; and by Fallopius, *pars tertii paris musculorum dorsi*. That part of it which is in the loins and back is called by Fallopius the *quartum par musculorum dorsi*, and seems to be the *sacer* of Riolanus.

That part which is in the neck is called by Riolanus also a part of the spinatus, and by some the *transversalis colli*: And its distinct portions in the neck are called by Douglass the *intervertebrales*.

MULTIPLE (*Cycl.*)—MULTIPLE *superparticular Proportion*, is when one number or quantity contains another more than once, and a certain aliquot part; as $3\frac{1}{2}$ to 1.

MULTIPLE *superpartient Proportion*, is when one number or quantity contains another diverse times, and some parts besides; as $4\frac{2}{3}$ to 1.

MULTIPLICATION (*Cycl.*)—Accurately speaking, in every *Multiplication*, the multiplicator must always be considered as a number; and it is easy to conceive a quantity of any kind multiplied by a number. But to talk of a pound multiplied by a pound, a debt by a debt, and a line by a line, &c. is unintelligible. However, by analogy, in the application of algebra to geometry, we meet with such expressions, and nothing is more common than to find $AB \times BC$, to denote the rectangle ABCD, the length of which is AB, and the breadth BC. But this is only to be understood by analogy; because, if the number expressing the measure of the side AB was multiplied by the number expressing the measure of BC, the product would express the measure of ABCD.

The sign of *Multiplication* most commonly used among algebraists, is $\times$. But the Germans, after Leibnitz, only make use of a point placed between the quantities multiplying each other, thus: $a \cdot b$ is the same as $a \times b$ and $AB \cdot BC$, the same as $AB \times BC$, or the rectangle of AB into BC, that is the rectangle ABCD.

When the quantities to be multiplied are complex, they place them between a parenthesis, instead of drawing a line over them, as we commonly do.

Thus they write $(a+b) \cdot (c+d)$ instead of $\overline{a+b} \times \overline{c+d}$, for the product of $a+b$ into $c+d$. Sometimes the point is omitted, thus: $(a+b)\ (c+d) = \overline{a+b} \times \overline{c+d}$.

MULTIPLICATION, in algebra. To multiply algebraic quantities, we must attend not only to the quantities themselves, but also to their signs.

The general rule for the signs is, that when the signs of the factors are like, (*i. e.* both + or both —) the sign of the product

product is +; but when the signs of the factors are unlike, the sign of the product is —.

Then if the quantities to be multiplied be simple quantities, find the sign of the product by the last rule; after it place the product of the coefficients, and then set down all the letters after one another, as in one word.

If the factors be compound quantities, multiply every part of the multiplicand by all the parts of the multiplier, taken one after another, and then collect all the products into one sum; which will be the product required. See *Maclaurin*, *Saunderson*, or any other elementary writers.

The reason of the rule here given for the signs of the product, *viz.* That + by +, or — by — give +, and that + by —, or — by + give —, is apt to perplex beginners. But if it be considered, that in all *Multiplication* the multiplicator is, strictly speaking, a number, the difficulty soon vanishes; for, 1°. When any positive quantity $+a$ is multiplied by any positive number $+n$, the meaning is, that $+a$ is to be taken as many times as there are units in n, and therefore the product is evidently $+na$ or na, the positive sign being omitted.

2°. When $-a$ is multiplied by n, then $-a$ is taken as often as there are units in n, and the product must be $-na$.

3°. As *Multiplication* by a positive number implies a repeated addition, *Multiplication* by a negative implies repeated subtraction; so that when $+a$ is to be multiplid by $-n$, the meaning is, that $+a$ is to be subtracted as often as there are units in n; therefore the product must be negative, being $-na$.

4. When $-a$ is to be multiplied by $-n$, then $-a$ is to be subtracted as often as there are units in n; but by the rules of subtraction, to subtract $-a$ is equivalent to adding $+a$, and consequently the product is $+na$.

The 2*d* and 4*th* cases may be thus illustrated, by the import and meaning of the signs + and —, $+a-a$ must be $=o$. Therefore if we multiply $+a-a$ by n, the product must vanish, or be nothing; because the factor $a-a=o$. The first term of the product is $+na$ by case 1. therefore the second term of the product must be $-na$, which destroys $+na$; so that the whole product must be $+na-na=o$. Therefore $-a$ multiplied by $+n$ gives $-na$.

In like manner, if we multiply $+a-a$ by $-n$, the first term of the product being $-na$, the latter term of the product must $+na$, because the two together must destroy each other, or their amount be o, since one of the factor $a-a=o$. Therefore $-a$ multiplied by $-n$, must give $+na$. See *Maclaurin's* Algebra, Part 1. chap 4. *Saunderson's* Algebra, Vol. 1. p. 57. And *Barrow's* Euclid, Schol. Prop. 1. Elem. 2.

MULTIPLIER, in arithmetic, the number multiplying. See the article MULTIPLICATOR, *Cycl.*

MULTIVALVES, in natural history, the name of a general class of shell-fish distinguished from the univalves, which consist of only one shell, and the bivalves, which consist of two, by their consisting of three or more shells.

Of these there are much fewer species than either of the univalve or bivalve class. A late accurate French author has ranked all the species under six genera, which are these: 1. The *echini* or sea-eggs. 2. The *vermiculi*, or sea-worms. 3. *Balani* or center-shells. 4. The *pollicipides* or thumb-shells. 5. The *conchæ anatiferæ* or goose-shells. And 6. The *pholades*. Hist. Nat. Eclairc. part 2. p. 235. All these see under their several heads.

MULTONES *Auri*, in our antient writers, an old coin of gold, having an *Agnus Dei*, sheep or lamb on the one side, and from that impression called *Multones*. This coin was most common in France, and sometimes current in England. Patent 33 Edw. 1. cited by the learned Spelman. *Blount.*

MULUD, in the materia medica, a word used by Avisenna and Serapio to express a sort of litharge, called by the Greeks *molybdites*, as seeming to partake of the nature of lead alone, not of gold or silver, or any other metal, as they thought the argyrites and chrysites did. This *Mulud* or molybdites was the least in esteem of all the kinds of litharge, and was of a dusky greyish white colour. It seems to be the same that Dioscorides means by *pelia* and *polia*, and sometimes by *lithargyrus Sicilius*, from the place whence it was brought.

MUMMY (*Cycl.*)—There are found at this time in Poland a kind of natural *Mummies*, or human bodies, preserved without the assistance of art. These lie in considerable numbers in some of the vast caverns in that country. They are dried, with the flesh and skin shrunk up almost close to the bones, and are of a blackish colour. In the wars, which several ages ago laid waste that country, it was common for parties of the weaker side to retire into these caves, where their enemies, if they found it out, suffocated them by burning straw, &c. at the mouth of the cavern, and then left the bodies; which being out of the way of injuries from common accidents, have lain there ever since. *Rzaczinski* Hist. Pol.

MUMMY, among the gardeners, is the term used for a sort of waxey composition used in grafting. It is made of one pound of common black pitch, and a quarter of a pound of turpentine, put into an earthen pot with a cover fitted to it; this is to be set in the open air, and the cover being taken off, the matter is to be set on fire, and when it has burned a little while, it is to be quenched by putting on the cover. This is to be repeated till the mixture is of a proper consistence, which is known by pouring a little of it on a pewter plate, on which, when it is enough, it will coagulate immediately. When it is of this consistence, it is to be poured into another pot, and a little yellow wax is to be added to it, and then melting the whole together, it is to be kept for use. *Miller's* Gardener's Dict.

MUNDUS *Patens*, among the Romans, a solemnity performed in a little temple of a round form; and dedicated to Dis, and the infernal gods.

It was opened only three times in a year, *viz.* on the day after the *Vulcanalia*, the 4*th* of October, and the 7*th* of the ides of November, during which days the Romans believed that hell was open; and therefore they never offered battle on those days, listed no soldiers, never put to sea, nor married. *Pitisc.* in voc. See the article VULCANALIA.

MUNDUYGUACU, in botany, a name of the *nux cathartica* of the West Indies, a kind of great ricinus, or palma Christi. *Piso*, 169.

MUNGATHIA, in zoology, the name given by some to a species of Indian ferret, of a reddish grey colour, called also *mungo*.

MUNGO, in zoology, the name of an American animal of the ferret kind, called by authors *viverra Indica ex griseo-rufescens*, or the reddish grey Indian ferret. Some call it also *mungathia*. *Mus.* Leyd. Cat.

MUNITION (*Cycl.*)—MUNITION-*Ships*, in the navy, those which have stores on board, to supply the necessaries to a fleet of men of war at sea.

In the time of an engagement, all the *Munition*-ships and victuallers attending the fleet are to take their places and proper stations in the rear of all the rest, and not engage in the fight, but attend such directions as shall be sent unto them, at all times, by the admiral.

MUNNY *Sheller*, in natural history, a name given by the natives of the East Indies to a species of red orpiment, which they have plentifully there. It is of a glowing colour, and has a great many shining spangles in it. They give this in fevers, after it has been calcined: It first melts in the fire, and then emits copious white fumes, smelling like those of arsenic. These are supppsed to contain the poisonous parts of it, and it then becomes a safe internal medicine, and is given with great success.

MUNTINGIA, in botany, the name of a genus of plants, the characters of which are these: The perianthium consists of one leaf, divided into large pointed segments. The flower consists of five roundish petals, of the length of the segments; of the cup. The stamina are numerous capillary filaments, they are very short; and the antheræ are simple. The germen of the pistil is globose, and is covered with hairs; there is nostyle, and the stigma is capitated and pentangular in figure. The fruit is a globose berry, with only one cell; it is umbilicated by the stigma. The seeds are very small and numerous, and are of a roundish figure. *Linnæi* Gen. Plant. p. 229. *Plumier*, Gen. 6.

MUNYCHIA, Μουνυχια, in antiquity, an anniversary solemnity at Athens, upon the fixteenth of the month *munychion*, in honour of Diana, surnamed *Munychia*. For the origin and ceremonies observed in it, see *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 414. seq.

MUNYCHION, Μουνυχιων, in chronology, the tenth month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our March and beginning of April. See the article MONTH.

It had its name from the festival *munichia*, kept in it.

MURÆNA, in the Artedian system of ichthyology, the name of a genus of fishes, the characters of which are these: They are of the malacopterigious or soft-finned kind. The branchiostege membrane on each side contains ten slender and curved bones; but the skin is so thick, that these are not easily distinguished before that is pulled off. The foramina of the nostrils are two, and are placed in the very summit of the snout, one on each side. The body is long and cylindric; in some species there are three fins, in others two, in others only one.

The species of *Muræna* enumerated by Artedi, are these: 1. The simple-coloured *Muræna*, with the lower jaw longest. This is the common eel. 2. The *Muræna*, with the upper edge of the back fin black. This is the conger, or sea eel. The iris of this fish is white; that of the common eel is red. 3. The *Muræna* with a sharp snout, variegated with white spots, and with the edge of the back fin black. This is the myrus of the antients, and the flat-tailed sea serpent of the later writers. 4. The cylindric-bodied *Muræna*, with no fin at the tail. This is the common sea serpent of authors; it grows to five foot in length. 5. The cylindric, slender, and spotted *Muræna*, with a rounded cuspidated tail, with no fin to it, This is the spotted sea-serpent of authors. 6. The *Muræna* with no pectoral fins. This is the fish which all authors call the *Muræna*, Artedi only extending that word as a generical name to the other species. *Artedi*, Gen. Pisc. 19.

According to *Willughby*, the *Muræna* is a fish of the anguilliform or eel-like class. Its body is broad, and its snout pointed, and of a flatted figure. It is variegated in colour with a dusky brown

brown or tawny, a black, and a gold yellow. Its head is moderately large, and its mouth extremely wide, and has, in the rim of each jaw, a row of very ſmall teeth, and in the middle of its palate, two teeth much larger than the reſt, and moveable inwards. Sometimes there is only one of theſe. At the end of its ſnout there are two ſhort and hollow apophyſes, and over the eyes two more. The former of theſe ſeem to ſerve the creature for hearing, and the latter for ſmell; for the antients all agree, that this fiſh can hear. The eyes are very ſmall, and placed in the middle of the head. It has two round holes at the gills for throwing out the water. The gills are four, and it neither has any fins at the gills, nor on the belly. Near the back part of the head begins a fin, which runs downs the ridge of the back, and ſurrounding the tail, returns up to the anus, and there terminates. This, as in the eel, is covered with the common ſkin. It is caught on the ſhores of Italy, and in other parts of the Mediterranean. Its fleſh is white, tender, and of a fine flavour, and was highly valued by the antient Romans. But there is ſome danger in the eating them. Their bite alſo is very venomous, and often occaſions long pain, and many ill conſequences to people who ſuffer it. *Willughby*'s Hiſt. Piſc. p. 103.

It is to be obſerved, that the dictionaries uſually give us the word lamprey as the Engliſh of *Muræna*; but the *Muræna* and lamprey, called by the Latin authors, *lampetra*, are two very different fiſhes. See the article LAMPETRA.

Muræna is originally Greek, and is derived from the *verb*, *μυρειν*, to flow, or be ſlippery, and expreſſes the manner in which its ſlipperyneſs makes it roll about, and eſcape the catcher, by ſlipping through his fingers.

MURÆNA is uſed by Albertus for the common ſmall lampern, the *lampetra parva fluviatilis* of authors. This is one of the petromyza of Artedi, and is diſtinguiſhed by the having only one row of very ſmall teeth in the verge of the mouth, beſide the large lower ones.

MURELIA, in botany, a name by which Pliny, and ſome other authors, have called the *parietaria*, or pellitory of the wall. *Ger.* Emac. Ind. 2.

MUREX, in natural hiſtory, the name of a genus of ſhell-fiſh, the characters of which are theſe. It is an univalve ſhell, beſet with ſharp ſpines and tubercles, with a rough clavicle exerted near the ſummit in moſt ſpecies, but in ſome depreſſed. The mouth is always expanded, and ſometimes has teeth, ſometimes not; the lip is ſometimes digitated, ſometimes elated or folded, or jagged; and the columella is ſometimes rough, ſometimes ſmooth. See Tab. of Shells, N°. 13.

Notwithſtanding that this is the general character of the *Murex*, and that all the ſpecies have an oblong mouth, and the body covered with tubercles, there are, under this extenſive character, four ſpecific variations of figure, which are very obſervable. The firſt is ſeen in the alated *Murex*, which has no ſpines. The ſecond is in the ſpider ſhell, which has very remarkable ſeries of fingers or hooks. The third is the helmet-ſhell, which is a true triangular *Murex*. The laſt is a furrowed *Murex*, which has no wings, nor protuberances, nor ſpines; but has a flat head, and an oblong dentated mouth. Hiſt. Nat. Eclairc. p. 290. *Aldrovand. Rondelet. Rumphius.* On the firſt examination of ſeveral of the ſpecies of helmet-ſhell, the outer coat of which is ſmooth, it would be natural to refuſe them any place among the *Murex* claſs; but when we ſee the oblong ſhape of the mouth, and find that it is furniſhed with teeth, and afterwards obſerve the rudiments of tubercles which are to be ſeen on the mouth ſide, we ſhall perceive that they are all true *Murices*, though leſs prickly than the others.

The antients were furniſhed with their fineſt purple dye from a fiſh of the *Murex* kind, and therefore expreſſed the purple colour by the word *Murex*. We find in Virgil, *Tyrio ardebat murice lana.* Plumier tells us, that in America the *Murex* is called *piſſeur*, from its readily ejecting the liquor, which gives the purple colour when it is taken from the rocks. And Fabius Columna diſtinguiſhes the *Murex* from the purpura and buccinum, but in a very injudicious manner. He ſays the purpura affords the fine purple colour: the *Murex* is covered with ſpines and tubercles; and the buccinum is known by its ſmooth and long wreath. But he ſhould have known that the affording the purple dye is common to the *Murex* and purpura, and even to ſome of the buccinum kind; and that there are *Murexes* with very few ſpines or tubercles, and buccina which are not ſmooth. The knowledge of the inſufficiency of theſe characters, would have engaged him in ſeeking others more eſſential; and a perſon of his great abilities would then perhaps have prevented half the confuſion that has happened ſince in the world, on occaſion of errors of this kind propagated from his writings, and thoſe of two or three others of his time. *Virg. Æneid.* L. 4. *Fabius Columna*, Aquat. & Terreſtr. Obſerv. p. 55.

The family of the *Murex* being very extenſive, it may be proper to divide them into ſome ſeparate ſeries from the general common marks of certain numbers of the ſpecies. 1. Some have remarkably eminent tubercles and ſpines. 2. Some are nearly ſmooth, but have a rough clavicle, and a crooked beak. 3. Some have digitated lips. And 4. Some have alated and laciniated lips. The ſpecies preſerved in the cabinets of the curious are theſe. Firſt, of the rough or prickly *Murices* we have the following:

1. The *Murex* with a compreſſed clavicle, and with obtuſe black ſpines. 2. The grey *Murex*, with an exerted clavicle, and rows of black ſpines. 3. The *Murex* with a compreſſed clavicle, ſurrounded with bluiſh ſpines. 4. The yellowiſh *Murex*, ſurrounded with four rows of obtuſe ſpines. 5. The whitiſh *Murex*, with two rows of ſpines. 6. The brown and blue *Murex*, with three rows of ſpines. 7. The yellowiſh *Murex*, every where regularly beſet with ſpines. 8. The whitiſh *Murex*, with a purple dentated mouth, and with yellow low tubercles or umbos. 9. The white hedgehog *Murex* with black ſpines, and with a dentated mouth. 10. The muſic *Murex*, with a rugoſe columella. 11. The ruſtic muſic *Murex*. 12. The lightening *Murex*, with a rugoſe columella. 13. The variegated *Murex* with a rough exerted clavicle. 14. The undulated, contabulated and tuberous *Murex*, with an exerted clavicle. 15. The whitiſh ſtriated *Murex*, with a clavicle furniſhed with long ſpines. 16. The yellow coſtated *Murex*, with furrows and tuberoſities on all parts of the ſhell. 17. The ſtriated umbilicated verrucoſe or warty *Murex*, with a reddiſh columella. Hiſt. Nat. Eclairc. p. 290.

Of the ſecond ſeries of the *Murex*, or thoſe which have a ſmooth body, a clavicle ſomewhat rough, and a crooked beak, we have the following ſpecies: 1. The triangular *Murex*, or helmet-ſhell of Rondeletius, with a dentated mouth and folded lip. 2. The red turban *Murex*, with ſeveral umbones, and with both lips folded back and expanded. 3. The helmet-ſhell of Bonani, or the agate helmet-ſhell, with a leſs dentated mouth. The laſt appearance is that under which we uſually ſee this ſhell, it having been commonly poliſhed, and its outer coat taken off, before it is admitted into a cabinet. 4. The yellow variegated helmet-ſhell. 5. The grey ſtriated helmet-ſhell, without umbos. 6. The whitiſh helmet-ſhell, variegated with yellow undulated lines. 7. The agate helmet-ſhell, with regular yellow ſpots. 8. The blue ſtriated helmet-ſhell, with yellow undulated lines. 9. The wavy helmet-ſhell.

Of the third kind, or thoſe which have digitated lips, we have the following: 1. The common ſpider-ſhell or *Murex*. 2. The ſpider-ſhell called by the French the *Murex lambis*. 3. The hooked-clawed or male ſpider-ſhell. 4. The female ſpider-ſhell. 5. The millipede ſpider-ſhell. 6. The cornuted ſpider ſhell of Rumphius. 7. The ſeven-fingered ſpider-ſhell. 8. The five-fingered ſpider-ſhell. 9. The four-fingered ſpider-ſhell. 10. The ſpider-ſhell, with ſix elegant furrows. 11. The ſcorpion-ſhell, with a radiated mouth. 12. The ſtrait-pointed red ſpider-ſhell. 13. The crow-billed ſpider-ſhell, or the blue, white and yellow ſpider-ſhell, with five appendages at the lip. This latter appearance is that under which we ſee the ſhell when it has been poliſhed.

Of the fourth ſeries of *Murexes*, or thoſe which have alated and laciniated lips, we have the following ſpecies: 1. The aſſes-ear *Murex*, with a crooked beak, and a lip red on the inſide. 2. The triangular *Murex* with large ſtriæ and tubercles, called the hogs-eared *Murex*. 3. The *Murex* with a red mouth and black columella. 4. The *Murex* with a ſtriated mouth, black on each ſide. 5. The white and brown-mouthed *Murex*. This, when poliſhed, is the ſpecies called the *turtle Murex* in cabinets. 6. The ear *Murex* of Rumphius. 7. The *Murex* with a reddiſh laciniated and very wide extended lip, and an aculeated clavicle. 8. The red *Murex*, with a laciniated lip and prickly clavicle. 9. The variegated and verrucoſe *Murex*, with a thick laciniated lip. 10. The variegated and verrucoſe *Murex*, with a jagged very thin lip. 11. The yellow *Murex*, with a laciniated lip and gibboſe clavicle. 12. The lead-coloured, bellied *Murex*, with a folded lip. 13. The ſmooth *Murex*, with a thick folded lip, and a dentated columella. 14. The yellow and tuberous *Murex*, with a folded lip, dentated on one part, and ſpotted on the other. 15. The yellow *Murex* with a regular rib, ſpotted, and running tranſverſely from the beak to the middle of the back. 16. The grey coſtated *Murex*, with a wide lip on the ſide of the columella. 17. The white coſtated and contabulated *Murex*. To theſe ſpecies is to be added one of a very ſingular kind, the mouth of which opens the contrary way to all the others. Hiſt. Nat. Eclairc. p. 288.

MUREX, among the antient Romans, a caltrap or iron inſtrument with ſharp points every way, uſed as a defence againſt the enemies horſe. *Pitiſc.* in voc.

MUREX *Mutiani*, a name given by ſome authors to the genus of ſhells, known at this time under the name of *porcelains* and *conchæ venereæ*. See the article PORCELLANA.

MURINA, or MURINES, *μυρινης οινος*, in antiquity, a delicious ſweet wine, medicated with ſpices. It was a kind of hippocras, and the uſual drink of the ladies. *Hofm.* Lex. in voc. See the article HIPPOCRAS, *Cycl.*

MURRA, among the antients, a foſſile ſubſtance found in Parthia and Carmania, of a fine ſmell, and beautiful variety of colours.

It was thought to be ſome humour condenſed in the earth by the heat of the ſun. *Pitiſc.* in voc. See the articles MURRINE and MORRHINA, *Cycl.* and *Suppl.*

Murra was likewife a dry perfume, made of the *Murra* reduced to powder. *Pitisc.* in voc.

MURRE, in zoology, a name given in fome parts of England to the razor-bill. See the article Alka.

MURRHINA, in antiquity, a kind of fweet medicated wine. See the article Murina.

MURRINE, in the writings of the antients, a name frequently given to cups ufed for drinking, and to veffels of a fmall fize, ufed for the preferving perfumes, &c. and called *Murrina* from *murrha* or *myrrha*, the name of the fubftance from which they were made.

There have been many errors among the critics and commentators about this *Murrha*; but the greateft of all is that of Baronius, who fuppofes it to have been myrrh, the gum we now know under that name. The defcriptions and ufe we hear thefe veffels were put to, plainly proves the abfurdity of this opinion. Some have fuppofed thefe veffels to be made of cryftal, but this is contrary to the account of all the antients.

The Greeks had the words κρυσταλλος for cryftal, and Σμυρνη for myrrh, very common among them, and therefore if thefe veffels had been made of either of thefe fubftances, they would in fome places have called them *Smyrnina* or *cryftallina*. On the contrary, the moft correct among them call them *murrhina* or *morrina*. The cups made of cryftal, which were alfo in ufe at thofe times, were called *cryftallina*, and thefe *murrhina* or *murrhæa*, by way of keeping up the diftinction: And Martial tells us, that the ftone they were made of was fpotted or variegated, calling them *pocula maculofæ murræ*. And Statius mentions the cryftalline and *murrhine* cups in the fame fentence, but as different things, not the fame. Arrian mentions alfo the λιθος μοῤῥινα, which his interpreters cenfure as an error of the copies, and would alter into *myrrha*, the name of the gum *myrrh*. See the article Morrhina.

MURROBATHRARII, among the Romans, a kind of perfumers. See the article Murra.

MURUCUIA, in botany, the name of a genus of plants, the characters of which are thefe: The flower is rofaceous, or compofed of feveral petals arranged in a circular form. The cup alfo is compofed of many leaves or fegments. The middle of the flower is occupied by a tube in the fhape of a truncated cone; from this there arifes a piftil, which has a tender embryo fruit, furrounded by three club-fafhioned bodies, with numerous ftamina underneath. The embryo finally becomes a fruit of an oval fhape and flefhy fubftance, unicapfular, and containing many feeds covered with a fort of hoods. See Tab. 1. of botany, Clafs 6. *Tourn.* Inft. p. 241.

The only known fpecies of this plant is the *Murucuia*, with lunated leaves, called by others, the fcarlet-flowered Indian climber, with lunated leaves.

MURZAROLT, in falconry. See the article Falcon.

MUS, the *Moufe*, in the Linnæan fyftem of zoology, makes a diftinct genus of animals, of the order of the glires, and taking in the whole family of the moufe and rat kind. The generical characters are, the having four toes on the fore-feet, and five on the hinder, and their palms made and fafhioned for running. *Linnæi* Syft. Nat. p. 39.

Of this genus there are feveral diftinct kinds: 1. The *common Rat*. This is a too well known animal; its colour is a dufky brownifh grey; its tail is compofed of a multitude of rings, not lefs than a hundred and fixty.

2. The *water Rat*. This is much larger than the common *Rat*, and is of a fomewhat reddifh brown colour; its feet are webbed, or the toes connected by membranes like thofe of a duck; it tail alfo is much fhorter, and all the way of the fame thicknefs, not tapering off, but feeming as if cut off in the middle; its teeth alfo are much longer, and of a pale yellowifh colour.

3. The *mufk Rat*. This is about the fize of our common *Rat*; its hair is long, and very thick fet; its back black, and its fides and belly grey. The head is fmall, and the nofe long and fharp, as if intended, like that of the hog, for digging up the earth. Its mouth does not open very wide; its eyes are extremely fmall, and its jaws adorned with a number of long grey hairs all along the opening of the mouth. Its tail is as long as its body, and is flatted and befet with a few fcattered hairs. Its feet are divided into five toes, the larger ones connected by a membrane to affift the creature in fwimming, and the hinder legs are fomewhat longer than the fore ones. This creature is common in Ruffia, and has a very ftrongly perfumed fmell like that of mufk. *Ray's* Syn. Quad. p. 217.

4. The common *Moufe*. This is too well known to need any defcription; but it is diftinguifhed from the reft of the genus by its fmallnefs, and its prominent large eyes. Its colour is a dufky grey on the back, and a whiter grey on the belly.

5. The *larger Moufe*. This is of twice the fize of the common *Moufe*, and is ufually found in caverns of the earth in the fields, though fometimes alfo in houfes; its back is of a mixed colour of black and tawny; its belly very white; and there is an even line drawn along each fide, which feparates the two colours; the head is longer than that of the common *Moufe*, and the eyes larger and more prominent; the ears are rounder and wider; and the tail very long, and covered with fhort hairs, black on the upper part, and white underneath. The legs alfo are longer than in the common *Moufe*; and there are fix tubercles in the bottom of the foot. *Ray's* Syn. Quad. p. 218.

6. The *great-headed field Moufe*. This is larger than the common *Moufe*, and its head is remarkably large in proportion to its fize. Its nofe is fhort and blunt. Its eyes fmall, and not prominent; and its ears, fhort, broad, and roundifh, and almoft entirely hid in the furr, which is much deeper than that of the common *Moufe*. This has alfo a much longer body, and its tail is remarkably fhort, and is thinly covered with hairs; its legs alfo are very fhort. Its back is of a very deep and dufky brown, with a mixture of yellow; and its belly is of a fort of lead colour, the points of all the hairs being white, and their bottoms black. It is common in dry paftures, and is abundantly diftinguifhed from all the other kinds by the thicknefs of its neck and fhoulders, and the fhortnefs of its tail.

7. The *great long-tailed field Moufe*. This is very nearly of the fize of a rat; its tail is very long, and its ears fhort and round; its head is thick, and the nofe not fharp, as in moft of thefe creatures, but fhort and rounded, and is of a deep brown, with fome mixture of red at the fides; and it has a fort of beard of long hairs between the mouth and the eyes.

8. The *Dormoufe*, or fleeper, called *Mus avellanorum* by many authors, and *forex* by Pliny. Of this there are two diftinct kinds, a greater and a fmaller. See the article Sorex. The other kinds are, 9. *Citillus*. 10. The *Cricetus*. 11. The *Marmotta*. 12. The *Cavia Cobaya*. 13. The *Aguti*. 14. *Paca*. 15. The *Leming*. And 16. The *Glis*. All which fee under their feveral heads. Befide thefe there is alfo another variegated kind, known by the name of the *ftriated indian-tree Moufe*, which is very rare, but is fometimes found in the cabinets of the curious. *Ray's* Syn. Quad. p. 218.

Mus *Alpinus*, in zoology, a name given by many authors to the mountain rat, more commonly known by the name of the *marmott*. See the article Marmotta.

Mus *Araneus*, in zoology, the name of a creature called in Englifh, the *fhrew*, the *fhrew-Moufe*, or the *hardy-fhrew*.

It is of mixt brown, and reddifh tawny colour; the belly is white. Its tail is about two fingers breadth long, and covered with fhort hairs. The whole body of the creature has a rank, offenfive, and poifonous fmell. It body is about three fingers breadth, and its eyes black and very fmall; they are indeed little larger than thofe of the mole, and do not exceed the fize of the head of the fmalleft pin; it is no wonder therefore that the creature is almoft blind. The teeth are very fmall, and differ in their fhape and fituation from thofe of all other creatures in the world; and feem as if nature had in one creature made a fort of mixture of the teeth of the *Moufe* and the fnake kind.

It has two long fore teeth, as all the *Moufe* kind have; but thefe are not fingle, as in *Mice*, but have two or three other fmall and fharp teeth growing out of them: Thefe, to an inaccurate obferver, might either be wholly unfeen, or taken for diftinct teeth; and the anterior long teeth are not feparated from the reft by any gap or fpace, as in the *Moufe* kind, but make one continued feries with the others. The upper jaw in this creature is longer than the under, and the teeth are fharp and ferrated, fome with two, fome with three points; and thefe fo fmall, that they might eafily not be feen, but that the tips of them are reddifh. *Ray's* Syn. Quad. p. 240.

It is very common in many parts of the world, and is met with in almoft all our dry grounds; the cats will kill it, but never attempt to eat it.

It is diftinguifhed at firft fight from the common *Moufe*, in that it is fmaller; its nofe longer, and like a hog's; it has five toes on the hinder as well as on the fore feet; its eyes are extremely fmall; its ears very fhort; its claws are long and whitifh, and its feet fhort.

Mus *Norwegicus*, in zoology, the name given by authors to the Norway rat, commonly called the *leming*. See the article Leming.

Mus *Pharaonis*, *Pharaoh's Rat*, a name given by the people of Ægypt to the ichneumon, a creature of the weafel kind, which they are very fond of for its deftroying ferpents, and keep tame about their houfes as we do cats. See the article Ichneumon.

Mus *Terræ*, in botany, a name given by fome authors to the roots of the *bulbocaftanum* or earth-nut; it was probably at firft *muris terræ radix*, the earth moufes root, and fo called from the *earth-Mice* or *field-Mice* being very fond of them; but the word *radix* being left out, it ftands only *Mus Terræ*.

MUSA, in botany, a large herbaceous plant, approaching to the growth of trees. Almoft all the writers of botany have looked upon the *Mufa* as a tree, on account of its bignefs; it is tender, fucculent, and not at all woody; the ftalk, though very thick, is fo weak as to be unable to fupport itfelf, were it not for a great number of dry cafes or hufks, which are membranous and thick, and defend it from bowing and from the weather. The *Mufa* alfo is an annual plant, which bears fruit only once, and then by degrees perifhes; whereas all trees are woody, perennial, and bear fruit a great many times. It has been by fome writers enumerated among the palmaceous

ous clafs; but this feems very idle, as they are all trees, and have no refemblance with the *Mufa*, except in their having naked ftems. The leaves of the *Mufa* at firft have no refemblance to thofe of the palms, but afterwards as they dry and wither they fplit on each fide into a vaft number of fibres which have fome fort of refemblance with the palm-leaves.

The Indians diftinguifh no lefs than twenty-five fpecies of *Mufa*, which they know from one another principally by the fruit. Philof. Tranf. N°. 410.

MUSADA, a name given by fome chemical writers to fal-armoniac. See the article SAL.

MUSCA, the *Fly*, in the hiftory of infects. See the article FLY.

MUSCA, in antiquity, a defignation given to parafites, buffoons, *&c.* who intruded themfelves into the company of thofe that defpifed them, or found means to be admitted to entertainments where they were not welcome. *Hofm.* Lex. univ. in voc.

MUSCÆ is alfo ufed for officers of the popifh inquifition, who feign themfelves of the fect of the prifoners, in order to draw a confeffion of their opinion from them, and thereby betray them; there being perfons placed to overhear their converfation. *Hofm.* Lex. in voc.

MUSCÆ *Volitantes*, dark irregular veins and fpots, feeming to fly before the eyes of many people, efpecially on looking at bright objects, fuch as white paper, the fky-light, the candle, *&c.* Thefe have often the appearance of flies, fpiders, cobwebs, fometimes that of fmoke, duft, *&c.* The refemblance of many of thefe fpots to flies have given them the name of *Mufcæ Volitantes*, q. d. flies flying about.

This phænomenon is not eafy to account for. Some will have its caufe to lie in the aqueous humor; others in the retina. Monf. de la Hire's account of them is this: They are of two forts, fome permanent, which, in fixing the eye upon a point of an object, appear always fixed in the fame fituation to that point; others feem to fly about, and to change their fituation, though the eye be fixed. The fhapes of both forts are changeable. The firft fort are commonly like a dark fpot upon a white ground; the fecond fort appear like the knots of a deal board; fome parts of them being very clear and furrounded with dark threads; they are alfo attended with long fillets of irregular fhapes, which are bright in the middle, and terminated on each fide by parallel black threads. On fixing the eye upon an object, they appear to defcend gradually; efpecially after fhaking the head fuddenly.

The fpots that appear fixed in refpect to the axis of the eye, muft, for that reafon, be caufed by fome diforder in a correfponding part of the retina, or in fome part of the vitreous humour lying pretty clofe to the retina. For an opacity of the coats or humours in any part remoter from the retina, by intercepting fome part of the rays of every pencil, could only caufe an uniform obfcurity or faintnefs of light in every place of the retina, and not a total defect of it in any particular place. Hence M. de la Hire attributes the caufe of thefe permanent fpots to fmall drops of extravafated blood upon the retina.

But he finds it more difficult to account for the moving fpots. When the rays of the fun are tranfmitted through a piece of bad glafs, and fall upon white paper, the fhadows of the little fands, veins, and irregularities in it, appear not unlike thofe fpots. He therefore imagines the aqueous humour is fometimes troubled with fome little mothery, ropy fubftance; fome parts of which, by the figures of their little furfaces, or by refractive powers, different from the humor itfelf, may caft their diftinct images upon the retina. He fuppofes them in the aqueous humour, rather than in the vitreous; becaufe of its greater fluidity for a freedom of defcent, and becaufe they will then appear to defcend, as being fituated before the pupil, or at leaft before the place of the interfection of the pencils. But if this heterogeneous mother be in the vitreous humor, it muft be lighter than this humor, fo that after a fudden fhake of the head, it may firft defcend a little, and then afcend gradually, to caufe the gradual apparent defcent above-mentioned. La Hire *Differt. fur les differ. accidens de la vue.*

Thefe fpots are obferved to change their figures, fometimes in two or three hours, at other times not in two or three days; and to appear more numerous at one time than another. Id. ibid. and Dr. *Smith*'s Optics in the Remarks, Art. 27. feq.

We have an inftance in the Philofophical Tranfactions, N°. 384. of thofe fixed fpots above-mentioned. A woman, who, in looking with the left eye only, at three fhort words in print, could fee the extremes, but not the middlemoft; and, in looking with the right eye only, at the middle between four fhort words, could fee but three of them; one of the two middlemoft being covered with a dark round fpot; but in looking with both eyes fhe could fee them all.

Pitcairn denies the caufe of the *Mufæ volitantes* to lie in the aqueous humour, and fays it is owing to, and a fign of, an internal inflammation of the veffels of the retina. Heifter thinks them owing to fome obftruction of thofe veffels; and both thefe authors, and many others, think them forerunners of a gutta ferena, or a cataract; and propofe a cure by mercurials and decoctions of guaicum. See *Pitcairn*'s Elem. Medic. & *Heifter*'s Compend. Medic. Practic. Plempius has given a defcription of the *Mufcæ volitantes*, in his Ophthalmographia.

Dr. Porterfield, in the Medical Effays of Edinburgh, obferves, that thefe fpots may proceed from fome little extravafations, verrucofe fwellings, or other defects in the retina, which by intercepting the rays will occafion a defect in the picture; and by confequence a fimilar and correfponding defect or fpot in the object. He obferves alfo, that thefe fpots commonly vanifh, or at leaft become lefs fenfible, when the object is brought nearer the eye, and within the limits of diftinct vifion. For, the rays which are now exactly united upon the retina, by being more crowded have their force augmented; by which means a fenfible impreffion is made upon the retina through thefe extravafations. Hence thefe fpots are moft fenfible to thofe who have a fmall pupil, and efpecially to thofe who are fhort, or long-fighted. Hence alfo, in a prefbytical eye, the fpots which were formerly very fenfible, become faint, when the object is viewed through a convex glafs; for by means of this glafs more rays enter the eye, which being united exactly at its bottom, muft ftrike the retina ftrongly enough to make a fenfible impreffion through thefe extravafations, which will render the fpots obfcure.

The learned doctor farther obferves, that what has been faid with refpect to thefe fpots, when occafioned by extravafations or the defects in the retina, will alfo hold when they are occafioned by a callofity, or any degree of paralyfis or infenfibility in fome parts of the retina by which the impulfe received from the rays is made lefs fenfible.

But, befides thefe defects in the retina, there is another caufe which may give occafion to thefe fpots, both in the *myopia* and *vifus fenilis*; and that is, certain fmall opaque marks in the cornea itfelf, or any where within the eye, which, by intercepting fome of the rays, muft occafion a defect in the picture, from which defect a kind of dark fpot will be feen in the object. Thus, in the eye of a myops, if there be any opacity in the cornea, or within the eye which intercepts the rays B*be*, C*cd*, and VL*a*, there will be a defect in the

picture at *e*, *d*, and *a*; from whence alfo the external appearance will be deficient at the correfponding points E, D, and A; where, by confequence, dark fpots will be feen. For it is to be obferved, that there is not one point in the picture which is formed by a plurality of rays which meet at the point, but every ray goes to a different point of the picture, both in myopical and prefbytical eyes; and therefore, when any of the rays are intercepted, that part of the picture to which fuch rays belong will not be illuminated, which muft occafion a correfponding defect in the appearance of the object. But in the perfect fight, where the rays which come from the feveral points of the object, are fo refracted as to meet again at fo many correfponding points in the retina, every point of the picture is formed by a cone of rays, whofe bafe is the pupil; and therefore, though fome of thofe rays be intercepted, yet no part of the picture will be darkened, and confequently no defect will be feen in the object from any fuch opacity in the cornea, or humors of the eye, unlefs this opacity be in the back part of the vitreous humor, where the pencil is narrow, and intercepts the whole pencil. This may be proved from the Camera Obfcura, by fticking fome fmall patches on the glafs. Thefe will not be perceived if the paper is placed at the due focal diftance; but if the diftance be greater or fmaller, the fpots will appear.

The doctor alfo obferves, that thefe fpots are not all of the fame kind. He thinks that thofe which change not their place with refpect to the axis of vifion proceed from fome defect either in the retina or cornea, or in the vitreous and cryftalline humors. As for thofe which are in conftant motion, he fuppofes them to arife from fome corpufcles floating in the aqueous humor.

Befides thefe dark fpots, there is another kind often met with, more bright and luminous than the object itfelf before which they

they appear. Theſe ſpots appear beſt by looking at diſtant bright objects, and are always of the ſame colour with the object. In the middle their colour is clear and ſtrong, ſurrounded by a dark ſhady border. They are commonly accompanied with certain irregular veins, which proceed from each ſpot, and which as well as the ſpots themſelves change their order and diſpoſition. Theſe veins are alſo of the ſame colour with the object, and being bright and luminous in the middle, are likewiſe terminated by a dark and obſcure edge. Theſe ſpots change their poſition with reſpect to the axes of viſion, according as the eye is differently moved, being ſometimes in the axis of viſion itſelf, and at other times to the right or left of this ſame axis; but when the eye is kept fixed in the ſame direction, they, as well as the dark kind of ſpots firſt mentioned, commonly deſcend gradually.

As to the cauſe of theſe brighter ſpots and veins, it ſeems that, firſt, they muſt proceed from ſome corpuſcles within the eye, which are at liberty to change their place, and which therefore muſt be ſuppoſed to float in the aqueous humor. Secondly, ſeeing theſe ſpots always deſcend when the eye is kept fixed, the corpuſcles from which they ariſe muſt aſcend; and are conſequently lighter than the aqueous humor in which they ſwim. Thirdly, theſe ſpots being more bright and luminous than the object, they cannot be occaſioned by any opaque corpuſcles, which by intercepting the rays would caſt a ſhade upon the retina. What therefore bids faireſt for producing theſe brighter ſpots and veins, is ſome ſmall, oily, diaphanous particles and filaments which ſwim in the aqueous humor before the cryſtalline; for ſuch, by their lightneſs, will aſcend, when left to themſelves; and by their greater refractive power, produce theſe luminous ſpots terminated by dark lines. That oily and ſulphureous ſubſtances, though leſs denſe than water, have a ſtronger refractive power, is evident from the obſervations of Sir Iſaac Newton. From which it follows, that the rays of light, which paſs through theſe oily particles, will meet ſooner behind the cryſtalline, than the other rays. Whence in a preſbytical eye, the rays of light which come from the ſeveral points of the object will not converge to ſo many other points in the retina, but behind it, by which the picture in the retina, will be rendered more dark and obſcure; but the rays which paſs through theſe oily grains, by having their refraction increaſed, will meet nearly at the retina, where they will form ſmall luminous ſpots, ſurrounded with dark borders.

But we muſt here obſerve, that the ſame appearances happen to myopes; and this ſeems difficult to account for from this theory of the learned doctor.

Many medical authors have looked on the *Muſcæ volitantes* as forerunners of a cataract, or gutta ſerena. And we ſuppoſe it cannot be denied, that many who have fallen into thoſe terrible diſorders have had thoſe appearances before their eyes; and hence they might have been taken for prognoſtics. But as it is no leſs certain, that many thouſands have the ſame appearances, and yet preſerve their ſight very well to the laſt, there ſeems to be no great reaſon to be alarmed about them; and far leſs ſhould people be running to quacks, and injuring their ſtomachs and conſtitutions by ill-judged phyſic on ſuch occaſions. St. Yves denies theſe appearances to be at all dangerous, and he thinks them owing to the ſeparation of ſome parts of the retina from the choroid. However, as the diſorder is troubleſome and alarming to the patient, he adviſes purgatives from time to time, and millepedes. We can ſay, from experience, that neither mercurials, nor ſea-water, nor other purgatives, nor millipedes, nor aqua Tunbridge or other chalybeate waters, have had any effect towards removing or diminiſhing theſe diſorders. A greater doſe of wine than uſual has been known tu increaſe it for a little time; and Plempius has made the like obſervation. We ſhall only add, that ſeveral of theſe flying appearances reſemble little globules joined by threads, thus 
and theſe globules appear in different numbers, and at different diſtances.

All authors agree, that theſe appearances change their figure; which is true, in ſome meaſure; but from our own obſervation we can ſay, that though they ſeem on a ſudden looking to the ſky, or other bright object, to vary in their figures; yet when they begin to deſcend, they return in one conſtant figure before we loſe ſight of them. On the whole it ſeems, this phænomenon is not yet fully accounted for. The vaſcular form of moſt of theſe appearances, their reſemblances to ſmall veins or arteries, makes it difficult to conceive them floating in the humors of the eye; and, on the other hand, their ſeeming contortions, and change of figure on ſuddenly looking up, or ſhaking the head, makes it no leſs difficult to conceive them fixed and obſtructed capillaries, as many authors ſuppoſe.

MUSCARI, in botany, the name of a genus of plants; the characters of which are theſe: The flower is liliaceous, but conſiſts only of one leaf, of a ſomewhat globular form, and divided into ſix ſegments at the edge; the piſtil ariſes from the bottom of the flower, and finally becomes a fruit of a ſort of triangular form, which is divided within into three cells, and uſually contains a number of roundiſh ſeeds.

The ſpecies of *Muſcari*, enumerated by Mr. Tournefort, are theſe: 1. The purple-flowered broad-leaved field *Muſcari*, called by authors the great purple boytroide or fair-haired hyacinth. 2. The broad-leaved field *Muſcari*, with white flowers. 3. The great blue-flowered *Muſcari*. 4. The broad-leaved elegant *Muſcari*. 5. The great white-flowered *Muſcari*. 6. The *Muſcari* with bluiſh green flowers. 7. The white-flowered byzantine *Muſcari*. 8. The branched *Muſcari*. 9. The ſmaller branched *Muſcari*. 10. The ſmaller broad-leaved blue-flowered *Muſcari*. 11. The leſſer ruſhy-leaved blue field *Muſcari*. 12. The leſſer fleſh-coloured flowered ruſh-leaved field *Muſcari*. 13. The little ruſhy-leaved field *Muſcari*, with white flowers. 14. The perfumed *Muſcari*, with a dark greyiſh flower. 15. The ſweet-ſcented *Muſcari*, with a browniſh flower. 16. The blackiſh-flowered *Muſcari*. 17. The yellow-flowered *Muſcari*. 18. The early yellow-flowered *Muſcari*. *Tourn.* Inſt. p. 347. ſeq.

We have ſeveral ſpecies of this plant cultivated in gardens: Three or four for the beauty of their flowers, and one with a purpliſh green flower for the remarkable ſweetneſs of its ſcent. In June, when the leaves of theſe plants are decayed, the roots ſhould be taken up, and ſpread upon mats in a dry place for a fortnight, till the bulbs are dried; then they may be packed up, each ſort by itſelf, till October, when they are to be planted in borders for flowering the following ſpring. They ſhould never be ſuffered to remain in the ground more than two years unremoved; for they multiply ſo faſt that the number of the off-ſets greatly weakens the flowering roots, and the flowers are conſequently ſmall. They are eaſily propagated by theſe off-ſets, which are ſo hardy as to grow even if buried a foot under ground; and the common kind propagates itſelf ſo faſt this way, that when it has once got poſſeſſion of a bed it is with great difficulty extirpated. *Miller's* Gardener's Dict.

MUSCERDA, a name by which ſome authors have called mouſe-dung, a thing recommended by many as a purge for infants; and ſaid to be good in alopecias. Given in clyſters it is ſaid to be of ſervice in many diſorders of the bowels; and externally applied, to be of great uſe in condylomata of the anus.

MUSCICAPA, in zoology, a name by which Aldrovand and ſome others have called the *ſtone-chatter*, making that bird, which is properly an œnanthe, one of the ſpecies of that genus or the fly-catchers. *Aldrovand* de Avid. See the article STONE-CHATTER.

MUSCICAPA, or the *Fly-Catcher*, is alſo the name of a ſmall bird of the ficedula kind, and very nearly allied to the beccifago, or petty-chaps. It is called alſo in ſome places, *chivin* and *borin*. It is a little larger than the wren, and has a very ſharp-pointed beak. Its head, neck, and back are of a pale grey, and its throat and belly of a yellowiſh white. Its rump is white; its wings grey; its tail, feet, and legs, are brown; and its claws very ſlender. *Ray's* Ornithology, p. 158.

MUSCLE (*Cycl.*)—Mr. Winſlow, in his treatiſe on the *Muſcles* in his *Expoſition anatomique de la Structure du Corps humain*, ſhews prodigious varieties in the actions of theſe organs of motion, which were never ſo much as hinted at before.

Dr. Waltherus, after comparing the *Muſcles* of the human body with the deſcriptions of them publiſhed by ſeveral authors, particularly by Mr. Winſlow, has made ſeveral accurate remarks on them, which may ſerve as a ſupplement to his *Anatome teneriorum Muſculorum repetita*. Nov. Act. Erud. June 1733.

The *Muſcles* in fiſhes are not placed lancellatim, or one upon another in a longitudinal direction; but they are generally laid either tranſverſely or ſomewhat obliquely one behind another, from the anterior part of the body to the origin of the tail. This ſtructure is beſt ſeen in the ſpinoſe fiſhes.

Theſe *Muſcles* of the ſpinoſe fiſhes may be conveniently divided according to their ſituation into the dorſal, pectoral, and neutral. After theſe, the inferior ones of that part of the body near the tail, are to have their place; and finally, the cephalic, or thoſe of the parts about the head.

The dorſal *Muſcles* have an interſtice in the middle of the length of the back, or are ſeparated longitudinally from one another, and are terminated in the ſides over-againſt the ſpina dorſalis. The pectoral and ventral *Muſcles* take their origin from the baſis of the ribs, and they meet in the middle of the breaſt and belly. The *Muſcles* of the lower part of the body ariſe along the ſpina dorſi, and meet one another in the bottom of the belly. The cephalic *Muſcles* ſerve to the moving the eyes and the jaws, and are principally four: one is placed on each ſide under the eyes, and one on each ſide in the lower jaw. The two former are called the hypophthalmic *Muſcles*, and the two others the maxillary *Muſcles*; they are moſt evident in the gadi, &c.

MUSCLES *of Vegetables*. The *Muſcles* in animal bodies have been the ſubject of numerous diſſertations; but thoſe in vegetables have been leſs regarded. Mr. Tournefort, however, has plainly proved, that many of the veſſels of plants become in the drying fibres capable of tenſion; that in many plants there are great numbers of theſe fibres which have all the ſame direction, and always act all together, and can only

ſhorten or contract themſelves in one particular direction; wherefore the parts compoſed of theſe fibres are very properly compared to the *Muſcles* of animals. By the word *Muſcle* we underſtand a part compoſed of fibres ſo determinately arranged, that by their contraction they can only move the part in ſome certain and determinate manner; and in this which ſeems the received ſenſe of the word, there are many inſtances in which it may be uſed to parts of plants, with the ſtricteſt juſtice.

All the pods of the leguminous plants, as peaſe, &c. are compoſed each of two valves, more or leſs convex on the outſide; theſe are placed evenly upon one another, and faſtened together by means of a great number of very fine veſſels; they are faſtned much more firmly together at the back, than at the fore-rim; and the large veſſels which carry nouriſhment both to the valves and ſeeds, are lodged there, and ſend many ramifications both to one and the other of the valves of the pod.

Each valve is formed of two ranges of fibres; the exterior arrangement is formed into a ſort of net-work, and the threads which compoſe it iſſue from the back of the pod, and are propagated longitudinally and ſomewhat obliquely through the ſurface of the valves, and finally terminate at the edge or fore-rim of the pod, after they have entered into the fleſhy part, with the net-like plexus of veſſels, of which they make frequent anaſtomoſes.

The interior plan or arrangement of fibres croſſes the exterior, in the ſame manner as the interior intercoſtal *Muſcles* in the human body croſs the exterior; and theſe form the inner membrane of the pod: Theſe fibres ariſe like the others from the back of the pod, and run obliquely to the edge. A neceſſary conſequence of this ſtructure is, that the arrangement of exterior fibres muſt become dry before the others, as muſt alſo the fleſhy ſubſtance in which they lie; and the conſequence of this is, that they muſt contract and draw the edge of the valve to which they belong at once upward and outward, and endeavour to ſeparate it from the edge of the other valve, drawing with it the interior arrangement of fibres; this therefore pulls open the pod, and the air which is very hot at the ſeaſon when the ſeeds of theſe plants ripen, inſinuating itſelf into the interſtices of the internal arrangement of fibres which are expoſed to it by the opening of the pod, ſoon acts upon them, and they begin to contract in their turn. Theſe fibres were once the veſſels which conveyed the nutritive juices to the pods and ſeeds; but when that uſe is no longer neceſſary for them, and when no more juices aſcend, after the ſeeds have arrived at their deſtined ſize, they then ſhrink up, and no more perform the office of veſſels, but become mere fibres. As theſe do not all dry up, and ſuffer this change together, but neceſſarily it happens firſt to thoſe which are ſituated at the greateſt diſtance from the pedicle, and conſequently thoſe are the firſt of the interior fibres which act by ſhortening themſelves; this therefore begins at the extremity of the pod, and is continued up to the pedicle, and the effect is that as theſe interior fibres are ſtronger and more numerous than the exterior, which are at this time as far ſhortned as they are capable of, they now draw backwards and inwards the lips of the edge of the pod toward the back. When the warm air acts upon theſe fibres to dry and contract them, it draws nearly equally at both their ends; and therefore if the two arrangements of fibres were regularly tranſverſe, each valve of the pod muſt be drawn by this action into a ſort of tube, or pipe; but as they are placed in an oblique direction, and parallel to one another, the natural effect of their contraction muſt be the drawing the valve into a ſpiral form, which we ſee is exactly the caſe. The lines which form the rim of each valve can make no reſiſtance to this contraction, becauſe they are ſo dried up by the warm air, and want of juices, that they may be crumbled to powder between the fingers, and eaſily break in any part with the ſmalleſt force. This claſs of plants gives numerous inſtances of this ſort of *Muſcles* in vegetables, and they are more obvious than moſt others, being not only common in the hedges but cultivated in gardens for the uſes of the kitchen, &c. The ingenious author of the ſyſtem gives many other inſtances in other plants. Mem. Acad. Par. 1693.

MUSCLE, in ichthyology, the Engliſh name of the *Mytulus.* See the article MYTULUS.

Horſe-MUSCLE. See the article HORSE-*Muſcle*.

MUSCULUS (*Cycl.*)—MUSCULI *capitis acceſſorii*. There is ſometimes found a ſmall *Muſcle* fixed by one end to the extremity of the firſt tranſverſe apophyſis of the neck near the inſertions of the two obliqui, from whence running up obliquely it is again inſerted behind the maſtoide apophyſis. This *Muſcle* is commonly thought to be a third ſmall tranſverſalis, on that ſide where it is found; but it ſeems rather to be an additional *Muſcle* to the obliquus ſuperior. The recti, and other obliqui are alſo found ſometimes double. *Winſlow*'s Anat. p. 238.

MUSCULUS *faſciæ latæ*, a ſmall and pretty long *Muſcle* ſituated a little obliquely upward, and downward on the forepart of the hip. It is fixed above to the outſide of the anterior ſuperior ſpine of the *os ilium*, between the inſertions of the *glutæus medius*, and *ſartorius*. From thence its fleſhy fibres run down a little obliquely backward, forming a very flat body four fingers breadth in length, and two in breadth. This body lies between two lamina of the *faſcia lata*, and is inſerted therein by ſhort tendinous fibres, which diſappear at that place where the *faſcia* adheres to the great trochanter, and tendon of the *glutæus maximus*. The *faſcia* is therefore by no means to be looked upon as a tendinous expanſion of this *Muſcle*. *Winſlow*'s Anatomy, p. 211.

MUSCULUS *Latus*. See the article LATUS *Muſculus*.

MUSCULUS, is alſo a name by which ſome call the common ſea *Muſcle*, more properly called *Mytulus*. See the article MYTULUS.

MUSCULUS *Myſticatus*, in ichthyology, a name given by Geſner and ſome other writers, to the common whale or *balæna edentula* of authors. This is diſtinguiſhed from all the other cetaceus fiſhes by Artedi, by the name of the whale with the fiſtule in the middle of the head, and with the back ſharp toward the tail. See the article BALÆNA.

MUSCULUS, among the Romans, a military machine, under cover of which the ſoldiers approached and undermined the walls of places beſieged, or filled the ditches. *Pitiſc.* Lex. Antiq. in voc.

MUSCUS *Arboreſcens Marinus*, in botany, a name given by Count Marſigli to a very elegant ſpecies of ſea-plant. It grows to the rocks at conſiderable depths under water, and is uſually of about three inches high; and is compoſed of ſeveral thick branches, furniſhed toward the tops with tranſparent leaves. The ſtalks are hollow, and it is all ſoft while in the ſea, but grows ſomewhat rigid when dried.

When examined by the microſcope, its ſurface appears to be granulated or covered with a ſort of ſmall glandules, which ſtand very near one another, and on cutting it tranſverſely the whole ſubſtance is ſeen to be hollow, and that general hollow to communicate with all theſe glandules, ſo that their office plainly is ſeverally to receive the ſea-water, and convey it into this general cavity, where it is diſtributed throughout the whole plant for its nouriſhment and ſupport. The leaves of this plant being rubbed on blue paper, give it a yellowiſh green colour.

Count Marſigli has gone through the analyſis of this plant, and as by it we may be informed of the principles and properties of many other ſea-plants of the ſame genus, it may not be improper to give an abſtract of his obſervations.

Four and twenty ounces of this plant being put into a retort, there came over five ounces of phlegm of a ſweetiſh taſte, and of the colour of oil of almonds. The ſpirit was of a duſky earth colour, of a fixed nature, of an unctuous yet ſomewhat acrid taſte, and leaving a bitterneſs behind it; of this there was twelve ounces, and the remainder in the retort was ſix ounces and three drams. So that the whole produce being twenty-three ounces and three drams, there was only five drams of the whole loſt in the operation. The water does not alter the colour of blue paper, on ſteeping in it; being mixed with the decoction of mallow flowers it turns it to an aſh-colour. The decoction of galls becomes of a bluiſh colour, and a ſolution of copperas of a greeniſh aſh-colour with it: The tincture of turnſol becomes of a bluiſh colour, tending to white. Spirit of nitre being added to it cauſes a ſlight fume, and the decoction of mallow flowers being after this added, a fine red colour is produced. Spirit of vinegar turns this green; and no change at all is produced by any of the following liquors, ſpirit of ſalt, ſpirit of ſal armoniac, lime-water, alum-water, oil of tartar: a ſolution of corroſive ſublimate collects a quantity of white and groſs particles, and precipitates them to the bottom. *Marſigli*, Hiſt. de la Mer. p. 73.

The ſpirit being examined with blue paper makes no change in its colour on being ſteeped in it; the decoction of mallow flowers mixed with it becomes of a pale yellowiſh green; the decoction of galls changes with it to a duſky red; a ſolution of copperas becomes of a dirty yellow, and thick; the tincture of turnſol changes to an aſh-colour. Spirit of nitre being mixed with it, cauſes a moderate fume without any ebullition, and the colour of the mixture is a reddiſh grey; on mixing the decoction of mallow flowers with this, it becomes of a yellowiſh red. Spirit of vinegar added, renders it more fluid and of a leſs duſky colour. Spirit of ſalt changes it to a reddiſh colour. Spirit of ſal armoniac, and oil of tartar, make no change at all; but lime-water renders it more clear and fluid. Alum-water collects a quantity of white matter, and precipitates it; and a ſolution of corroſive ſublimate, in like manner turns it white, and precipitates the groſs parts. The *caput mortuum* yielded one dram and ten grains of fixed lixivial ſalt; the taſte of this is but moderately acrid, and its colour a greyiſh white; being rubbed on blue paper it changes its colour to its own. The decoction of mallows on mixing this ſalt with it loſes its blue colour, and becomes grey; and on frequently ſhaking the veſſel, it finally becomes yellow. Spirit of nitre mixed with this ſalt does not ſo readily or violently effervesce with it, as with moſt other lixivial ſalts; and if a little turnſol be added to this, it becomes of the colour of red wine. Spirit of vinegar diſſolves it very quickly, and becomes thick and turbid with it. Spirit of ſalt diſſolves it very readily, but makes no fume, though a very conſiderable ebullition,

ebullition. Lime-water diffolves it flowly, and carries it to the furface; and alum-water, in like manner, on diffolving it is covered with a thick fcum at the top: Corrofive fublimate added to this, precipitates the falt again, without altering its colour. Spirit of fal armoniac, and oil of tartar, make no change upon it. It is remarkable, that this plant contains no volatile falt.

MUSCUS *Marinus latus*, the broad and flat fea *Mofs*, a fea-plant defcribed by Count Marfigli. It is found in feveral places at different depths, growing to the rocks and ftones. Its upper furface is compofed of a feries of leaves of an auriculated figure, amaffed together in an irregular manner; but its underfide is fmooth and even, except that it is befet with a number of foft points or eminences, which are not eafily diftinguifhed by the naked eye. Thefe, when a microfcope is ufed, are found to be fo many little white tubes of a cylindric figure; thefe are evidently the apertures by which the plant receives its nourifhment; for in this, as in the other fea-plants in general, when the root faftens upon a rock or ftone, it is not to extract nourifhment from it, but only to fix itfelf firm in its place by it; for the whole furface of the plant takes in nourifhment from the circumambient water, and every part acts as a root receiving fupplies for the whole. *Marfigli*, Hift. Mer. p. 73. See the article MOSS.

MUSEAU, in natural hiftory, a term applied by Mr. de Reaumur to a fort of bladder which the infects of the fly clafs are provided with to make their way out of their fhell, after their laft transformation into the nymph ftate.

The word is French, and literally fignifies a fnout or muzzle. The flies to whom nature has given this inftrument, have it only during that fhort ftage of their lives which is between their being enclofed in the membrane which covers them in the nymph ftate, and their firft flying about at liberty. At this time, in order to their getting out of their fhell, nature gives them a power of inflating and fwelling out their head to a great fize, and throwing out this fort of bladder from its anterior part, by which means the cap of the cafe or fhell is thrown off, and the end of it opened by the two longitudinal lines giving way. The creature, after this, as it has no ufe for this fingular piece of mechanifm, fo it has no power to exert it during the remainder of its life. *Reaumur*, Hift. Inf. vol. 4. p. 340. See the article TRANSFORMATION.

MUSEBYTER, in zoology, a name given by fome to the fifh called by authors *Dobula*, a German fifh, found in feveral parts of Germany; much approaching to our common dace. *Willughby's* Hift. Pifc. p. 261.

MUSEIA, Μεσεια, in antiquity, feftivals in honour of the mufes at feveral places of Greece, efpecially among the Thefpians, where folemn games were celebrated every fifth year. *Potter* Archæol. Græc. l. 2. c. 20. T. 1. p. 415.

The Macedonians had alfo a feftival in honour of Jupiter and the mufes, which was celebrated with ftage-plays and games, and lafted nine days, according to the number of the mufes. *Potter*, ibid.

MUSHROOM, *Fungus*, in botany, the name of a genus of plants; the characters of which are thefe. It is a headed vegetable compofed of a pedicle crowned with a broad head, which is convex and fmooth at the top, and hollow, foliated, lamellated or fiftulous on the other fide. See Tab. 1. of Botany, Clafs 17.

The fpecies of *Fungus*, enumerated by Mr. Tournefort, are thefe: 1. The common efculent *Mufhroom*, with a broad round head. 2. The *Mufhroom* with broad and round livid heads. 3. The large fweet-fcented royal *Mufhroom*. 4. The white *Mufhroom*, with a broad orbiculated head. 5. The yellow *Fungus*, with a flat ftalk, and rounded head. 6. The flatted round and hairy-headed *Fungus*. 7. The reddifh brown fmooth orbicular-headed *Fungus*. 8. The large flat orbiculated headed *Fungus*, with rough prominent veins. 9. The great *Fungus*, with a protuberant head variegated on the upper fide, and hairy underneath. 10. The plain-headed brown *Fungus*, with lacerated edges. 11. The broad-headed *Fungus*, with a long variegated pedicle. 12. The round-headed fpring *Mufhroom*. 13. The white-headed meadow *Mufhroom*. 14. The flat round-headed yellow *Mufhroom*. 15. The white and brown furrowed round-headed *Fungus*. 16. The brown bulbofe *Fungus*, with a double head. 17. The brownifh white *Fungus*, with pointed heads. 18. The fmall umbilicated *Fungus*. 19. The variegated navel *Mufhroom*. 20. The orbicular *Fungus*, with the edges bent inwards. 21. The angular *Mufhroom*, with jagged edges. 22. The thick porous *Mufhroom*. 23. The white wood *Mufhroom*, with an acrid pepper-like milky juice. 24. The broad fcarlet-headed *Mufhroom*, with a fweet and well-tafted milky juice. 25. The little milk *Mufhroom*, with very long and flender pedicles. 26. The great all-white efculent *Mufhroom*. 27. The white *Mufhroom*, called bifette. 28. The great-headed *Mufhroom*, with heads brown on the upper fide, and white underneath, and with a fpotted ftalk. 29. The yelluwifh red *Fungus*, with greenifh gills. 30. The great reddifh *Mufhroom*, with a fhort thick ftalk, and white gills. 31. The lamellated *Mufhroom*, with a broad thin and membranaceous head. 32. The yellow and white fmall vifcid meadow *Fungus*. 33. The red fmall vifcid meadow *Mufhroom*. 34. The fmall tender dufty *Mufhroom*, with heads grey on the upper fide, and covered on the under fide with thin black lamellæ. 35. The fmall *Fungus*, with a long pedicle, and a half-round yellowifh head. 36. The fmall *Mufhroom*, with a long tough and firm ftalk, and a head pointed at the top, and fhewing the fhell of the gills on the out-fide. 37. The fmall *Fungus*, with a long ftalk, and a head ftriated on both fides. 38. The very fmall *Fungus*, with a conic reddifh brown head, and a few lamellæ. 39. The very fmall whitifh grey *Fungus*, with a long flender pedicle, and but few lamellæ. 40. The dufky brown *Mufhroom*, with heads pointed at the top. 41. The conic-headed orange-coloured *Fungus*. 42. The yellow *Fungus*, growing in clufters about the roots of trees. 43. The brownifh *Fungus*, growing in clufters on rotten wood. 44. The white fhining *Fungus*, growing many together. 45. The larger fhield-fafhioned *Fungus*. 46. The fmaller fhield-fafhioned *Fungus*. 47. The red orbiculated marfh *Mufhroom*. 48. The fmall yellow funnel-fafhioned *Mufhroom*. 49. The white *Fungus*, with inverted heads. 50. The fmall turbinated clufter *Mufhroom*. 51. The velvety lamellated tree *Mufhroom*. 52. The fmall lamellated *Mufhroom*, growing to alders in the fhape of a comb. 53. The hard white tree-*Mufhroom*, with lamellæ refembling the blood-ftone. 54. The fmall white lamellated *Mufhroom*, with a long flender pedicle. 55. The white hairy tree-*Mufhroom*, lamellated underneath. 56. The orbicular hazel *Mufhroom*. 57. The orbiculated *Mufhroom*, called the toad-ftool. 58. The white infipid *Mufhroom*, with conic heads. 59. The white orbiculated birch *Mufhroom*. 60. The reddifh black orbiculated *Mufhroom*. 61. The flie *Mufhroom*, fo called becaufe it is faid to kill flies. 62. The broad white orbicular *Fungus*. 63. The broad orbicular *Fungus*, with the edges turning inwards. 64. The bulbous-ftalked *Fungus*. 65. The broad *Fungus*, with jagged edges. 66. The *Fungus*, with edges divided into five fegments. 67. The orbiculated autumnal oak *Mufhroom*. 68. The truffle-like *Mufhroom*. 69. The *Mufhroom*, refembling in colour and in fmell the root of fow-bread. 70. The thick conic-headed *Fungus*. 71. The red firr *Mufhroom*, with reflex edges. 72. The common greyifh white clufter *Mufhroom*. And, 73. The fcaly and globofe American fcarlet *Mufhroom*. *Tourn.* Inft. p. 556. feq.

Mufhrooms are plants more perfect than many people imagine; they have a regular root, a ftalk confifting of feveral arrangements of fibres, the interftices of which are filled up with a parenchymatous fubftance, leading from the root to the head or umbel; the under fide of this umbel is full of lamellæ or chives, every one of which is a regular pod or feed-veffel. If thefe lamellæ are examined in their feveral ftates, the feeds in them may be eafily difcovered, and are always found to be of a fize and degree of maturity proportioned to the ftate of the plant at that time; they have each of them alfo a filiquaceous aperture lengthwife, the feeds lying in rows ready to fall through it. The plant is eafily and regularly propagated through thefe, and not only may be raifed from feed, but, like many other plants, may be propagated by roots. The feveral filaments at the root producing tubercles, in the manner of the potatoe; from each of which there will arife new roots, and a new plant. The periods of vegetation in this plant are alfo fufficiently regular; and the common opinion of its fpringing up in a night, and perifhing in a day, has no foundation in reality. For, in the common way of raifing them on hot beds, it is eafy to find, that they often ftand a fortnight or longer from their firft appearance, before they are fit for the table. Phil. Tranf. N°. 472. p. 160.

Notwithftanding that the feeds of fome fpecies of *Mufhrooms* have been difcovered, the accurate Buxbaum is of opinion, that very many plants of this genus propagate themfelves greatly by root, and are truely perennial; and this he fupports by many folid arguments, drawn from obfervations of the feveral fpecies of *Mufhroom*, or *Fungus*, which are obvious and under the eye of every obferver, at many times of the year.

1. There are fome *Fungufes* which, while young, or when firft appearing out of the earth, ftand on a pedicle which is very lightly rooted, or does but penetrate a very little way into the earth; but after the head has expanded itfelf, and is withered, this bottom of the pedicle pierces deeper into the ground, and there acquires a greater thicknefs and becomes a fort of bulb, remaining there in that ftate till the next year, when it brings forth a new plant.

2. There are certain fpecies of *Fungufes*, which grow on the old ftumps of tree; thefe fend their roots deep into the fubftance of the rotting wood, where they alfo remain many years, and annually produce new *Fungufes* at a proper feafon. Of this fort is the clufter *Mufhroom* of old trees, defcribed by Mr. Tournefort; the roots of this, as of the former kind, do not begin to defcend or inlarge in length and thicknefs till the upper part of the plant withers; but they then begin to grow and often force themfelves into the crevices to a great length, and become ftrangely divaricated: To this is owing the erroneous account of fome authors of *Mufhrooms* or *Fungufes*, found fpreading and branching between the bark and the wood of old trees, fuch fuppofed *Fungufes* having been only

only the enlarged roots of some known species, whose upper part is decayed; but which, at a proper season, will be received from these roots. The agarics always grow upon trees, and wherever they are fixed, there is always a callous tubercle in the wood under them, which denotes the passage of the root. Thus what Breynius calls the leather-like blood-red oak *Mushroom*, is no other than the root of the common endive tree-*Mushroom*; and the cylindric tree-*Fungus* or touchwood of Dillenius, is only the root of the common cluster *Fungus* above described.

3. There is a species of *Fungus* which, while young, is round, and seems to have no fibres, or roots; but these at length decaying, become filled with a dry dust or subtle powder, and then they push down very numerous roots into the earth; and among these roots there are placed several globules, which are no other than compleatly organized *Funguses* of the same kind with the other, and ready to appear like it in a succeeding year. The common boletus, and several species of the lycoperdon, shew instances of this. Ray observes the same sort of propagation by roots in that species called *fungus phalloides*, which, he says, creeps a long way under the ground, with white fibrous roots variously interwoven one with another; and to which there are affixed, at certain distances, little globules, which are ripened into more *Funguses* of the same kind in a succeeding year. Acta *Petrop.* vol. 3. p. 265.

The violet-coloured *Fungus*, creeping on wood in manner of a herpes, described by Mr. Ray, is no other than the root of the violet-coloured mesenteric agaric, and the black compressed *Fungus* variously branching between the bark and the wood of trees, is the root of the black-fingered *Mushroom* of Mentzelius, or the plant itself impeded in some accident in its growing.

4. There are *Funguses* which creep with their pedicles, and shoot out roots from them; and now and then young plants, in the manner of the plants of the more perfect kind, which have creeping stalks; of this kind there are several species, which grow on the decayed fruits and leaves of trees, all of which plainly propagate themselves by the root.

In several species of these plants there is placed round the stalk, at a small distance from the head, a sort of ring of a tough matter, resembling the outer covering of the whole *fungus*; this usually catches many of the seeds of the plant in their fall from the head when ripe, in order to the re-producing the species; and hence some have been of opinion, that it was placed there by the author of nature, in order to break the fall of the seeds, and preserve them from the fury of the winds, in their falling from too great a height, in respect to their extreme lightness; but it rather appears, that the seeds often found on this ring, fall there only by accident, and are there detained by a viscosity with which that part of the plant abounds; and that the use of this ring is very different.

Linnæus has classed the *Funguses* in general, together with the fig-tree, the several species of the ferns, the mosses, and some others, under the character of *cryptogamia*; that is, such plants as perform the great work of their fructification in secret, or at least whose flowering and feeding are not observed so easily, as in those plants which we usually call the more perfect ones. In some of these the best microscopes have not yet been able to inform us of the true manner in which this is performed, and many of the *Funguses* or *Mushrooms* are of this number.

Almost all the *Mushrooms* which have thick and fleshy umbels, and fleshy stems, have this sort of ring round their stalk, from which, when the plant is young, and not yet in a flowering state, there arises a membrane which connects the rim of the umbel to the stem, and preserves the under part while in this state; but when this time is over, the umbel, which was before of an hemispherical figure, growing larger, and the membrane not giving way, it is torn off from the rim of the umbel, and adheres only to the stem. Soon after this the seeds ripen, and the umbel then losing its former figure, commences almost a plane. This is the state in which the plant is sold in our markets under the name of *flaps*.

When the umbel is of this figure, the seeds being perfectly ripe, must fall upon the whole space covered by the umbel, and as a part of this space the ring must receive its share of them; but there is no reason to believe that it receives more than are allotted to such a part of the determinate space on which they are to fall.

As to those species of *Mushrooms* whose stems are slender, and their umbels thin, soft, and ductile, they never have this ring at all, and yet their seeds have often farther to fall than those of the other kinds which have it, as they are usually taller plants. The rims of the tender umbels in these kinds clap themselves quite close to the stalks, in the form of a contracted umbrella, and expand as the others do when the seeds are ripe; and the species of *Funguses* of this kind are much more numerous than those of the former, and propagate themselves full as regularly.

The poison of *Mushrooms* has been much talked of by several persons; but there seems to be no certain account of any body's ever having been injured by eating the common *Mushroom*, unless by accident, as from the eating too many at once, and thereby over-loading the stomach; or by their being eaten by persons who had a particular dislike to them, as some persons have to the most innocent aliments, particularly to chese. If these *Mushrooms* had any poisonous quality, it must have been often found out by the physicians in such a place as London, where there are annually such vast quantities of them consumed, yet nothing of this kind is observed; and there seems, upon the whole, to be nothing hurtful in this species; though there may be many others which are truly poisonous. Nor is it any more wonderful, that the different subjects of this class of vegetables should differ in their virtues, than that those of other kinds should. The roots of carrots and parsnips are daily found a very wholesome food, while those of other plants of the same class, such as the water-hemlock, the dropwort, and others of the umbelliferæ are known to be poisonous.

The antients have taken great pains to distinguish the several kinds of *Mushrooms*, that the world might know the hurtful from the safe. The boletus mentioned by Juvenal, on account of the death of the emperor Claudius, is sufficiently described by Pliny. Clusius, among the moderns, has described a vast number of different species, every where distinguishing the esculent and wholesome from the poisonous or pernicious kinds. The several authors who have treated of them since the time of Clusius, have all mentioned the effects of some or other of the poisonous kinds; and there are numerous instances of the mischief done by them at one time or other. Some have been willing to ascribe this mischief to animalcules inhabiting the plant; but this seems erroneous, and particularly from the following instance: We have one kind of *Mushroom* growing in England, called the white acrid *Fungus*. This is so extremely sharp, that it stimulates the tongue, as if it had been touched with spirit of nitre: And Tournefort observes, that if rubbed on blue paper, it turns it red in the same manner as that liquor, or any other of the violent acid spirits would; this caustic quality remains in the plant even after drying; and it is very evident, that we need look no farther than this for the origin of the poisonous quality in this species. There is another kind which is observed to kill the very flies as they settle upon it. It is not probable that such plants as these should be inhabited by any kind of animalcules, nor is it necessary to have recourse to such causes of the mischief which ensues from the eating them, when their own juices seem so very able to have occasioned it. Philos. Trans. N°. 473. p. 54.

Mr. Miller says, that the true eatable *Mushroom* is distinguished from the poisonous and unpleasant kinds by these marks. When young it appears of a roundish form like a button, the stalk as well as the button being white, and the fleshy part very white when broken, the gills within being livid. As they grow larger they expand their heads by degrees into a flat form, and the gills underneath are at first of a pale flesh-colour; but as they stand long, become blackish.

In order to propagate *Mushrooms*, the meadows and pastures should be searched for them in August and September; and wherever they are found, the ground should be opened all about the roots, where there will be found abundance of small white knobs. These are to be taken up with lumps of earth about them. Then some new horse-dung must be procured; and the litter being shaken out, the dung must be laid together on a heap to ferment for eight days. A trench must then be dug, and the dung laid in it a foot thick, and covered over six or eight inches thick with light rich earth; and into this, on each side, should be put in the knobs of *Mushroom* spawn, as it is called, at six inches distance. After this another layer of dung is to be made upon this earth, to six or eight inches thickness, or more, but observing to draw in the sides, so as not to cover the knobs of *Mushrooms* above half an inch; then another layer of earth is to be laid on this, and some more knobs of the *Mushroom* spawn placed on this at the sides, as in the former; then put on a third layer of dung, drawing it in still narrower, that it may not cover the second plantation; and cover this with another layer of earth, drawing this up into a ridge at the top, and planting more of the *Mushroom* spawn in this; but still laying it in sideways as before. When all is thus finished, the whole bed is to be covered half a foot thick with dry litter, to prevent the earth from drying too fast. When the bed has been made a fortnight, it should be carefully looked over, drawing away the litter with the hands, to see whether any young *Mushrooms* appear; and they must be gathered as they grow large; for if suffered to remain, they will rot upon the bed, and destroy all the young spawn that is about them. And when they begin to produce, the bed must be searched every other day all the year round, and every day in August and September, which is the time of their principal increase, to gather such as are fit for use. The manner of gathering them is, to pull them gently out of the ground, so that no part of their stalk may be left behind; but if any part of the spawn is pulled up with the stalk, that must be carefully returned into the bed. As the cold or wet weather comes on, the covering of dry litter over the whole bed must be increased. A bed thus managed, will remain good many months, and produce vast abundance of *Mushrooms*; and the spawn may be at times taken out from it to supply other new beds.

beds. At whatever time of the year this is taken up, it ſhould be carefully laid up in a dry place till the month of July following, which is the proper time for planting it in new beds. *Miller's* Gardener's Dict.

The vaſt variety of known *Funguſes* which are found regularly every ſeaſon in their proper ſoils, are not all that the naturaliſt has to enquire into the nature of; there are others whoſe productions are much more ſurprizing. Theſe are ſuch as are only ſeen once or twice in an age, and that in places where it is very difficult to account for the manner of their production. One of theſe we had ſome years ago, which appeared upon an old piece of wood in a blackſmith's cellar in the Hay-market, and grew to twelve inches or more in height; and, when cut down, appeared again at the ſame time the next year, and ſo on for ſeveral ſucceeding years, as if, contrary to the nature of the generality of theſe plants, it had a perennial root, and grew regularly from the old ſtock. This appeared to us a ſingular production, and a wholly new ſpecies; but ſo long ago as in the year 1692, Mr. Tournefort found ſuch a one growing on an old beam in the abbey at St. Germains. His deſcription of it is very accurate; and its reſemblance with ours as great as could be expected, in ſo looſe a growing plant as an irregular *Fungus*. It was compoſed of a cluſter of five large and thick leaves, and made ſomewhat of the appearance of the tympanum of the capital of a Corinthian pillar, but in a coarſe way; it was about ſix inches high, and nine inches wide; and each leaf or part was about half an inch in thickneſs. They were all very ſolid, and capable of continuing a long time without decay. They all aroſe from the ſame baſe, and forming pedicles ſeparately, they again united, and made a broad and beautiful aſſemblage of joined leaves to the top. They expanded a little above this joining, each into the figure of a deer's horn; and at the edges were ſo cut and ſinuated, that they not unaptly reſembled the leaves of certain cut and curled cabbages, common in our gardens; they were of a pale yellowiſh colour, like that of buff-leather, and had a border of a ſtronger yellow about their outer edge; the internal ſubſtance was white, and very hard and firm, though light, and was pierced in different places with a vaſt number of holes, many of which were large, and reſembled thoſe of a ſpunge or pumice; theſe all had apertures on the ſurface of the leaves; and theſe apertures, when examined with a microſcope, were found to be ſurrounded with a wrinkled rim, covered with a very fine and ſubtil powder, the greater part of the grains of which hung to a fine filament, and might be taken for the ſeed of the plant. The back-ſide of the leaf was more ſmooth and gloſſy than the other. It had ſeveral ribs, which run out into ramifications, that might eaſily be traced by the eye to their extremities at the edges of the leaf; and this part of the leaf was in many places covered with a ſort of tartarous cruſt, which ſeemed to be a ſort of placenta or ovary; but on examination there appeared no rudiments of ſeeds in it. The beam on which this *Muſhroom* grew was very firm and ſound in all other places, but juſt where it was rooted there was a crack out of which moiſture ouzed; and probably the beam was in that part rotten, or worm-eaten within. The ſmell of the plant was like that of others of the ſame kind, and an infuſion of a piece of it turned an infuſion of turnſol to a bright red; ſo that it manifeſtly abounded in acids.

It is not eaſy to account for the appearance of theſe plants which are ſeen ſo rarely, and that in places where no plant could be expected to grow: the only probable ſolution of the point ſeems this, that as the ſeeds of the *Muſhroom* kind are all very minute, and generally in theſe ſpecies which have no lamellated heads, cover the whole ſurface of the leaves, the number of ſeeds produced by one ſuch plant muſt be numerous beyond all account, and at the ſame time light enough to float about in the air. Theſe muſt be at times thrown againſt a thouſand different bodies where there is no proper nouriſhment for them, and muſt therefore periſh; whereas if many accidents are required to concur, to make a ſoil proper for it to grow in, wherever ſuch ſoil happens to be produced, as the air has free acceſs every where, it is not impoſſible but that, at one time or other, one of theſe ſmall ſeeds may happen to be properly depoſited. Mem. Acad. Par. 1692.

The Laplanders have a way of uſing *Funguſes*, or common toadſtools, as we call them, as the Chineſe and Japoneſe do the moxa, to cure pains. They collect the large *Funguſes* which they find on the bark of beech and other large trees, and dry them for uſe. Whenever they have pains in their limbs, they bruiſe ſome of this dried matter, and pulling it to pieces with their fingers, they lay a ſmall heap of it on the part neareſt to where the pain is ſituated, and ſet it on fire. In burning away, it bliſters up the part, and the water, diſcharged by this means, generally carries off the pain. 'Tis a coarſe and rough method, but generally a very ſucceſsful one, eſpecially when the patient has prudence enough to apply it in time, and reſolution enough to bear the burning to a neceſſary degree.

MUSHROOMS *growing out of Flints.* Naturaliſts have of long time obſerved, that there are ſea *Funguſes* of a very different ſubſtance and ſtructure from any of the common kinds, growing on rocks, ſtones and corals, or other ſtrong ſea plants, which ſeem wholly incapable of ſupplying them with any vegetable nouriſhment. Theſe have been ſuppoſed to be as it were all root, and to take in their nouriſhment at every part of their ſurface from the circumambient water: But in the year 1739 Mr. Aleſeld obſerved a like ſort of *Funguſes* growing in places where they had no ambient fluid to afford them nouriſhment, except the air, and yet were fixed upon as unpromiſing a baſis for the ſupplying them with any, as thoſe of the ſea. Theſe were found on common flints on the ſurface of the earth. This gentleman obſerved, that a great many various ſpecies of flints which lay in part buried in the earth, and in part lying above its ſurface, were on this open part covered with a ſort of white duſt. This was in July, and in hot dry weather. Having the curioſity to examine this duſt with a microſcope, every particle of it was found to be a compleat and perfect *Fungus*, all of the ſame determinate figure, and much reſembling the common earth *Muſhrooms*. They were white in colour, and had each a very ſhort pedicle, in many, ſcarce to be ſeen at all; their head was round and umbilicated, and very elegantly and evenly ſtriated on the upper part, the ſtriæ or furrows all running from the center to the circumference; and the rim of each head being a little elevated. Upon the whole, they not unaptly reſembled in miniature a common tea-cup inverted, and the ſaucer inverted alſo, and placed upon it. The ſubſtance of theſe *Funguſes* was of two kinds, the one furniſhed a cortical part or covering, and the other filled up the whole internal ſpace.

The internal part was ſoft and ſpongy, and much like what the inſide of the common *Muſhroom* is: this was white. The outer or cortical part was reddiſh, and rather repreſented a congeries of ſmall grains of ſand, collected into that form by ſome glutinous matter, than any ſolid or continuous body. The thin external coat of this being removed, there were ſeen within it a multitude of ſmall round globules of gloſſy ſurfaces, reflecting the light in manner of ſome of the ripe ſmooth ſummer fruits, ſuch as the cherry, and the like. This was their appearance when freſhly uncovered; but after they had been expoſed ſome time to the air, they became flaccid, fell almoſt flat together, and were umbilicated and marked with rays from a center like thoſe of a ſtar.

Theſe *Funguſes*, if not injured by accidents, remain in their perfect ſtate a long time upon the ſtones. Five months keeping produces no alteration in them; but at length they become flaccid and wither, and in this ſtate are not to be recovered by water, as many of the common land *Funguſes* will, which ſwell, and for a time appear plump on being wetted.

They grate harſhly like ſtony matter between the teeth, and reſiſt the force of acid menſtruums; they bear the great degrees of heat or cold without any injury; but if they are expoſed to a flame, the outer covering of the head burſts and flies off, and theſe red globules come in full ſight, while the reſt of the *Fungus* remains unaltered. The ſame effect is produced by plunging them into hot water; and if they be boiled in water, over a ſtrong fire, the globules are diſlodged and loſt in it. If the flints on which they are produced, are heated red hot, the *Funguſes* are deſtroyed, and wholly diſappear in the places where they were; only the fragments of the outer covering of the head remaining ſcattered, on different parts of the ſtone, like pieces of broken pots or glaſſes: theſe fragments loſe their red colour, and are found grey. On the whole, it appears from theſe experiments, that the cortical part of this *Fungus* is not of the nature of common vegetable matter, but is truly ſtony; ſo that the plant may be properly arranged among a ſet of *lythophyta*, or ſtone plants, properly ſo called. The author of this curious diſcovery obſerves, that he uſually found many ſmall red inſects running about upon theſe ſtones, and among the cluſters of *Funguſes*. Theſe afforded at leaſt a proper retreat or nidus for them, if not food; for it is poſſible the internal part of the *Funguſes* might be eaten by them. Act. Eruditor. Ann. 1739.

Baſtard MUSHROOM. See the article FUNGOIDES.

Pepper MUSHROOM. See the article PEPPER.

MUSHROOM *Galls*, in natural hiſtory, a name given by authors to a ſmall ſpecies of galls very common on the leaves of the oak in September and October, and reſembling the common eſculent *Muſhroom*. They are placed on the upper ſurface of the leaf, and are often in great numbers on the ſame leaf, ſome containing twenty or thirty, and others only three or four. The leaves which have conſiderable numbers upon them, make a very beautiful figure, and appear as if ornamented by art with a number of elegant figures. Theſe galls are uſually about a ſixteenth, though ſometimes a tenth of an inch in the diameter; they are compoſed of an orbicular head, which adheres to the leaf by a very ſhort pedicle, ſo that its edges, which droop a little in the manner of thoſe of the common *Muſhroom*, uſually touch the ſurface of the leaf all round. Theſe little galls are of various colours, according to their different degrees of maturity; they are of a greeniſh white at firſt, after that they become of a yellowiſh tinge, from which they paſs through all the ſhades of orange and flame colour, to a very beautiful red, which is always their colour when perfectly mature. When they are obſerved by the microſcope, their ſurface appears hairy, and the ſeveral

 hairs

hairs all ſtand near one another at their baſes, and diverge at their points, as is the natural conſequence of their ſtanding on a convex body. *Reaumur*, Hiſt. Inſects. vol. 6. p. 194.

The uſe, as well as the figure of this gall is very ſingular. Malpighi and Mr. Reaumur have both deſcribed it, and the former of theſe authors deſcribes a cavity in the center of the head; but this ſeems to have been done at random, and rather ſuppoſed from analogy, than ſeen in fact; for the latter author, who is perhaps one of the moſt accurate obſervers that ever wrote, could never find any cavity in any one of the great numbers he diſſected; but he obſerved what was an uſe of the ſame kind with that of the other galls, in this, though performed in a different manner; they are plainly all deſtined for the lodgment and ſecurity of ſmall animals; and as, in the generality of them, theſe little creatures are contained in their ſubſtance, ſo in this they are ſheltered from injuries by it, though in another manner. For although there are not inſects lodged in the ſubſtance of it, there are always a great number found in the ſpace, encloſed within its circumference, as its edges every where touch the ſurface of the leaf, and the whole forms an arched dome with an upright pillar or pedicle in the middle. Theſe worms perfectly reſemble in figure thoſe of the lime galls, but they are of a yellow colour. There are uſually found a dozen or more of them under one gall, though ſometimes there are only two or three, or but a ſingle one. Theſe are ſo ſmall as not to be diſtinctly ſeen without the help of glaſſes; but they are of the nature of thoſe worms which turn into two-winged flies. Their manner of living is the ſame as that of thoſe contained in the ſubſtance of galls, for they continually ſuck and gnaw the inſide or under ſurface of the gall, and thence it increaſes in growth till they have done eating. *Reaumur*, Hiſt. Inſ. vol. 6. p. 19.

The flies into which theſe worms are finally transformed, have not yet been diſcovered; but this is no wonder, ſince the animals themſelves are ſo minute as to require glaſſes to view them. It is probable that they undergo their change into the chryſalis ſtate in ſome other place, for they are never found in it under the galls; but this is common alſo to many other ſpecies.

Mushroom *Worms*. The various ſpecies of *Muſhrooms* are ſubject to be eaten and deſtroyed by a great variety of inſects. There is however one ſpecies which is more frequent than all the reſt, and which has therefore obtained, among authors, the name of the *Muſhroom worm*. This is a white worm, with a hard ſcaly black head; it has ſome fleſhy tubercles, which it throws out at pleaſure from the under part of its ſeveral rings, and which ſerve it as legs. This is found indifferently in almoſt all the ſpecies of *Muſhrooms*; but in none ſo frequently as in the great wood-*Fungus*, which is porous and greeniſh underneath. Theſe worms have been watched in vain by ſeveral curious obſervers, to know what would be their laſt ſtate; but the difficulty was, that when the *Muſhrooms*, with the worms in them, were put into boxes for their transformation, they ſoon corrupted and ran into water, in which the worms were drowned. The putting earth in the box under the *Muſhrooms*, ſucceeded no better than this, the *Muſhroom* moiſtening all the earth about it too much by its decay, to ſuffer the worms to live in it: At length Mr. Reaumur found the proper method, which is, to put only ſmall fragments of the *Muſhroom* on large beds of earth in large boxes; and in this caſe the worm uſually lives to change into its nymph ſtate, and by this means at length acquires its perfect ſtate, and is found to be a tipula or long-legs of no great beauty, being of a duſky brown colour, and middling ſize.

The other ſpecies of *Fungus*'s have alſo their worms; but there is one of a very ſingular nature, which is found frequently on the agaric which grows on the ſtumps of oak-trees, eſpecially near the roots. This is a long and ſlender worm, ſomewhat flatted, and reſembling a ſmall leech, but that it has a hard and ſcaly head of a blackiſh colour. The body is compoſed of many rings, in the manner of the earth worm, and looks very bright and gloſſy, being always covered with a viſcous liquor. This creature is eaſily found, for it never eats into the ſubſtance of the *Fungus* but only crawls about upon its ſurface; the traces, wherever it has been, are marked with a coat of a ſhining varniſh, and reſemble the places over which ſnails have crept. There is ſomething very ſingular however in this creature's uſe of the viſcous humour it is covered with, which is not obſervable in the ſnail kinds. It is an extremely tender creature; and nature ſeems to have given it this liquid covering as a defence againſt the injuries of the external air, which would otherwiſe ſoon dry it up and kill it. This it defends itſelf from in the following manner: It fixes upon a place where it deſigns to remain ſome time, and then begins to make itſelf an habitation, by extending this viſcous matter, by means of its mouth, over a ſpace of the ſurface of the *Fungus*, which is more than equal to the bigneſs of its body; it doubles the coat of matter ſeveral times, ſo as to form a ſoft bed, on which it lays itſelf down, and then, by drawing its head ſeveral times from the ſides upwards, it extends two other plates of this glutinous matter, which dries into a thin ſkin immediately on being expoſed to the air. Theſe meeting in an angle over the body, form a ſort of covering like the ridge of a houſe, under which the creature lies, and is by this means defended from the air, as much as neceſſary, and yet is at liberty to feed at pleaſure. This ſort of covering is perfectly tranſparent, and is yet ſtrong enough for all the purpoſes it is intended for. This worm has no legs, but its manner of marching forward is by applying its head to ſome diſtant part of the ſurface of the agaric; there it drops a large drop of this viſcous matter, which ſoon hardens, and retains the head ſo firmly, that it is able to draw all the body to it. This is a ſort of motion that anſwers all its purpoſes very well, as it has but a very ſmall ſurface to crawl upon, and needs make but very ſhort journeys even upon that. This creature ſeems never to corrode the ſubſtance, or even the outer ſkin of the *Fungus*, but to live entirely upon the clear and glutinous fluid that covers the ſurface of this kind of agaric.

This worm makes a very beautiful object for the microſcope. When young it is as tranſparent as glaſs, and the motion of its internal parts is very eaſily diſtinguiſhed. It has two brown ſpots near the head, which look very like eyes, and the aperture, out of which the glutinous matter with which it makes its habitation iſſues, is very large, and ſeems the mouth. When this little creature is taken out of its habitation, it very ſoon dies, the air drying up all its liquid covering. The ſpots which reſemble eyes are really the anterior ſtigmata, and there are two others behind. When this creature is to paſs into the chryſalis ſtate, it does not remove from the *Fungus*, but ſpins itſelf a web, and remains upon it. This web is compoſed of the ſame matter with the covering or habitation under which it uſually reſides, but it is thicker, more opake, and of a coarſer ſtructure. The creature begins it by drawing ſeveral longitudinal lines, and other tranſverſe ones, as thick and ſtrong as it can make them; theſe compoſe the beams and raftors, or the open ſhell of the edifice; over and under theſe its ſpreads ſeveral continued plates of this glutinous matter, and theſe all drying in a very little time upon one another, form a fine and ſtrong ſhell, which it makes rough and uneven by farther additions; and finally cloſing the orifice, it works within, and ſtrengthens it yet much more, ſo that it is liable to no injuries from the weather, or from the common deſtroyers of theſe things, which are a ſmall ſort of carnivorous worms, which never attempt to force this covering. The creature remains about a fortnight under this covering, and then comes forth in the form of a fly, which is evidently a ſpecies of tipula. It has very long legs, and a long and ſlender body; the body is brown, and the breaſt yellowiſh; the wings are long and ſlender, and the antennæ are of a very ſingular and remarkable figure; they are broad and flat, and yet terminate in a point. Theſe are compoſed of ſeveral articulations, and make a very beautiful figure when examined by the microſcope. Beſide theſe, this fly has, in the manner of the other tipulæ, a pair of beards placed on the anterior part of the head, which it at pleaſure bends down over the face, and compleatly covers with them the longitudinal fiſſure, which is the mouth, ſituated in this as in the other tipulæ. *Reaumur*, Hiſt. Inſ. vol. 9. p. 23. ſeq.

MUSIC (*Cycl.*)—*Muſic*, among the antients, was taken in a much more extenſive ſenſe than among the moderns. Meibomius [a] from Porphyry enumerates its parts by the names *harmonica*, *rythmica*, *metrica*, *organica*, *poëtica* and *hypocritica*. Alypius [b] alſo and Voſſius [c] make the *harmonica*, *rythmica* and *metrica* to be ſo many parts of *Muſic*. Ariſtoxenus [d] adds the *organica*. Voſſius alſo to the three ſpecies of practical *Muſic*, *harmonica*, *organica* and *hydraulica*, adds a fourth, *orcheſtria*, or dancing. Ariſtides Quinctilianus defines *Muſic*, the knowledge of what is graceful and becoming in ſounds and motions [d]. What we call the ſcience of *Muſic*, was by the antients rather called *harmonica*.—[[a] In. Not. ad *Euclid*. Introd. Muſic. p. 41. [b] Page 1. Edit. *Meibom.* [c] De Scient. Mathem. c. 22. [d] Γνῶσιν τοῦ πρέποντος ἐν φωναῖς καὶ κινήσεσι. V. *Wallis*'s Appendix ad Ptolem. Harm. p. 153.] See the article Harmonica.

Chromatic Music, *Muſica Chromatica*, among the Italians, is uſed to expreſs that kind of *Muſic* in which there are many chromatic ſigns, as flats or ſharps, and intervals, &c. See the article Chromatic.

Diatonic Music. See the article Diatonic.

Didactic Music, *Muſica Didactica*, that part of ſpeculative *Muſic* which only conſiders the quantity, proportions, and different qualities of ſounds.

Dramatic Music, *Muſica Dramatica*, *Scenica*, or *Theatrale*, among the Italians, is uſed to denote ſuch compoſitions of *Muſic* as are particularly made and fitted for theatres. See the article Recitativo.

Enharmonic Music. See the article Enharmonic.

Musica *Ennunciativa*, or *Ennarrativa*, is uſed in much the ſame ſenſe as *Muſica ſignatoria*. See the article Musica *ſignatoria*, infra.

Figurate Music, *Muſica Figuralis*, *Figurata*, or *Colorata*. *Figurate Muſic*, that wherein the notes are of different values, and the motions various, now ſlow, then quick, &c.

Harmonic Music, *Muſica Harmonica*, among the Italians, is uſed for pieces conſiſting of many parts, which, though very different, yet, when played together, make an agreeable whole. This we call *Muſic* in parts.

Hyporchematic, or *Choraic* Music is used by some authors for a sort of *Music* fit for ballads and dancing.

Instrumental Music is used to denote musical compositions made to be executed by instruments.

Melismatic, or *Melodic* Music, is used to denote a song, or single part, merely for a voice or for an instrument. *Brossard*. See the article Melody, *Cycl.*

Melopoetic Music is the science or art of ranging and disposing sounds in succession in an agreeable manner; or the art of making melody. See the articles Melody and Melopoeia, *Cycl.*

Measured Music, *Musica Misurata*, among the Italian authors, a kind of *Music* the notes of which are unequal. It is contrary to *Musica Piena*, or *Chorale*.

Metabolic Music, *Musica Metabolica*, among the Italians, is properly *Music* transposed, as when the piece goes out of its natural mode into a transposed one, the better to express the words, or to distinguish some change in the action, passion, motion, &c.

Metric Music, *Musica Metrica*, is used by Italian authors, to denote the harmonious cadence of the voice, heard when any one declaims, or repeats verses; or it is an air composed to verses.

Modern Music. See the article Modern.

Modulatory Music, *Musica Modulatoria*, among the Italians, that part of *Music* which teaches to compose or modulate, *i. e.* that fixes rules for the use of modes, and teaches either to sing or play well. See the articles Mode, and Modulation, *Cycl.*

Odic Music, *Musica Odica*, among the Italians, is the same with *hyporchematic*, or *choraic*. Vid. supra.

Organic Music, *Musica Organica*, among the Italians, is used to denote musical compositions designed to be performed by instruments only.

Pathetic Music, *Musica Pathetica*, is a moving and affecting kind of *Music*, that causes emotions in the mind, either of love, grief, or pity.

Poetic Music, *Musica Poetica*, is sometimes used for the art of inventing songs, of modulating concords and discords together agreeably, and making what we call compositions, &c.

Recitative Music, *Musica Recitativa*, *scenica* or *dramatica*, a sort of *Music* used in operas, &c. irregular as to time, being a declamation in singing, to express the passions: From its being thus irregular in its time, the Italians often place the phrase *a tempo giusto*, when the recitative ends, and an air, be it minuet, jigg, or any other, follows, to shew that the time is then strictly to be observed.

Rhythmic Music, *Musica Rythmica*, is used for the harmony or cadence of the words in prose; or a song composed to words in prose. *Brossard*.

Scenic Music, the same with *Recitative*. See above.

Signatory Music, *Musica Signatoria*, is used for that part of *Music* which teaches the knowledge of the characters, notes, figures, pauses, and all other signs and marks whatever, used in *Music*.

Vocal Music, *Musica Vocale*, or that composed for the voice, in opposition to organical or instrumental, which is intended to be played on instruments only.

Music *Shell*, in natural history, the name of a species of shell-fish of the murex kind, remarkable for its variegations, which consist of several series of spots placed in rows of lines, like the notes of *Music*.

MUSICAL (*Cycl.*)—Musical *Numbers* are 2, 3, and 5, together with their composites. They are so called because all the intervals of music may be expressed by such numbers. See the article Interval.

This is now generally admitted by *musical* theorists[a]. Mr. Euler seems to suppose, that 7 or other primes might be introduced; but he speaks of this as a matter doubtful and difficult[b]. It is to be observed, that 2 corresponds to the octave, 3 to the fifth, or rather to the twelfth, and 5 to the third major, or rather the seventeenth[c]. From these three may all other intervals be found[d].—[[a] *Euler* Tentam. Nov. Theor. Mus. p. 62, 163. Dr. *Pepusch* in Phil. Trans. N°. 481. p. 267, seq. [b] *Euler*, ibid. p. 163. [c] Phil. Trans. ibid. [d] *Euler* & *Pepusch*. loc. cit.]

MUSIMON, in natural history, the name of an animal esteemed a species of sheep, described by the antients as common in Corsica and Sardinia, and found in no other part of the world. It is much to be suspected, whether the animal described under this name is now any where to be found in the world; not that it is to be supposed that any species of animal once created is become extinct, but that this probably was a spurious breed between two animals of different species, perhaps the sheep and goat, which like the mule not being able to propagate its species, may have failed ever since. Theodore Beza, indeed, gives an account of an animal, which he received from an ignorant countryman of Sardinia; which, he said, was peculiar to that place, and was called *muslo*; that its hide and hair was like that of a deer, its horns wholly like those of a ram, curling back to its ears, and its size that of a middling stag; and that it fed on vegetables, and lived among the rocks. The tragelaphus of Bellonius differs little from the *Musimon*, according to the descriptions of both. *Ray's* Syn. Quad. p. 75.

MUSK (*Cycl.*)—*Musk*, and other perfumes of the same tribe, have been long celebrated as antispasmodics, but were formerly ordered in such small quantities as to have little effect. Practitioners thought four or five grains a large dose. But the Chinese have taught us to be more bold; the tenth part of an ounce is an usual dose among them. The remedy in the east for the bite of the mad dog contains 16 grains of *Musk*, and this they repeat frequently. See the article Madness.

The effects of *Musk* are, ease from pain, quiet sleep, and a copious diaphoresis. Hence it has been found of great use in spasmodic disorders, petechial, malignant, putrid fevers, the goal distemper, hiccoughs, *subsultus tendinum*, &c. For the particular cases we refer to the Philosophical Transactions, N°. 474. §. 18.

It has also been found useful in spasmodic disorders, given by way of clyster, as Dr. Wall observes, in that Transaction.

The operation of *Musk*, in some respects, resembles that of opium; but is in this much preferable, that it does not leave behind it any stupor or languidness, which the latter often does. *Musk* therefore seems likely to answer in those low cases where sleep is much wanted, and opiates are improper.

It is said to be best given in a bolus, and that those who are most averse to perfumes, may take it in that form without inconvenience. For, as Etmuller and others, have long ago observed, the smell of the perfume is often found to be of disservice, where the substance inwardly taken produces good effects, Phil. Trans. ibid.

It is pity that a medicine of this consequence should be so liable to adulterations, and that the criteria of its genuineness are ill settled.

In a paper read before the Royal Society March 17, 174⅞, several cures performed by *Musk* on distempered cows, were mentioned.

When *Musk* begins to decay, it is a practice used in the East-Indies to put it into a bladder or bags, wherein many small holes are made with a needle, and hang it in a necessary house, but not low enough to touch the filth. Others keep it wrapped up in linnen, well moistned with rank urine. *Boyle's* Works abr. Vol. 1. p. 146.

Mr. Boyle says of his own knowledge that *Musk* has greatly contributed to the preservation of flesh. Works abr. Vol. 1. p. 30.

Musk-*Ant*, the name given by Lister and Ray, to a peculiar species of *ant*, which is of the number of the perfumed insects. It is found on dry banks, and is so much smaller than the common ant, that it needs no other distinction. Those of this species which are without wings are of a yellowish colour, and when bruised or crushed emit a sharp and acid smell, as the common ant does; but those which have wings are coal-black, and these, instead of the four smell of the others, emit a perfume not to be endured for its strength. The smell of all the perfumed insects goes off in keeping; and these little creatures, after they have been dead and dry some time, are found to smell less strongly, but much more agreeably. Phil. Trans. N°. 76.

Musk-*Insect*, a term used by some to express the capricorn, or *Musk* beetle; but it is too loose a phrase for that animal, since there are other insects which smell as strongly of that perfume. There is a small kind of bee very frequent in the pastures of Lincolnshire, and several other parts of England, in April. This frequents the ranunculus and dandelion flowers, and has a very strong and fine scent of *Musk*. There is also a hexapode worm, which feeds on the *gallium luteum*, or yellow ladies bedstraw, which has the same perfumed scent in a no less degree. Both these insects, and even the capricorn beetle, lose their perfume when they have been some time dead. Phil. Trans. N°. 76. See the article Capricorn *Beetle*.

Musk-*Rat*, an animal very common in several parts of America, and greatly resembling the beaver in all respects, except size. A full grown *Musk*-rat might very naturally be mistaken for a beaver of about a month old. And Mr. Sarazin, of the Academy at Paris, observes, that the Indians call these the same animals, only distinguishing the beaver by the name of the elder, and the *Musk*-rat of the younger brother. They live in summer on all sorts of plants, and in winter on the great roots of the water-lilly. They live in communities, at least they always do so in winter, and erect themselves certain habitations of different sizes, some suited for the reception of only one family, others for a great number of such. Their great care is employed in the chusing a proper place for these habitations; for it is necessary that they should be not only defended from the injuries of weather, but freely open to the water, and that without fear of inundations; and they must also be in the neighbourhood of large plantations of the roots on which they are to feed. To have all these necessary conveniencies they always build in the steep banks of some river, which has a level bottom, and a wide bed without too much depth; and as such rivers always abound with the roots they

want; they have thus always a dry home, plenty of provisions, and no danger of inundations; for they are prepared for little risings of the water, by having upper stories or rooms, into which they retire when the ground-floor is uninhabitable; and rivers of this great breadth and small current, are not subject to any very high floods. Mem. Acad. Par. 1732.

The size of the room is always well proportioned to the number of the intended family; if it be only for seven or eight, then a room of two foot square does, and it is made proportionably larger as the number is to be greater. When they have laid out the plan of their habitation, they plant a parcel of rushes all around it, which they surround in a very artful manner with clay, pressing it down with their feet, and working it even with their tail, which is like that of the beaver, and serves them for a trowel. They have a passage out of their house, which they go out at daily as long as the weather continues tolerably mild; but when it becomes very severe, they block up this passage, and the whole habitation afterwards often becomes covered many foot deep with snow; in this case they keep within doors, and have wells which supply them with water; other holes which serve to receive their excrements; and they burrow under ground to the river, and seek for the large roots they are to feed upon.

In this season, if they are at some difficulties to get food, they have the advantage however of being out of danger of the huntsmen, who know not where to seek them in the snow; but when the thaws come on, which is usually in March or April, they discover and take great numbers of them; if this season be slipped, however, they generally escape, for soon after this the melting of the snows cause inundations, which happen at no other times, and which drive them out of their habitations into the higher countries; in this time they single one another out for the propagation of the species, and even this is a scene of some danger to one sex, for the huntsmen find the way to imitate the courtship of the female, and will by that noise draw severally many males about them, which they shoot as they come in reach. After the time of copulation is over, and the waters are abated, the females return to their old lodgings, and there bring forth and nurse up their young; the males run about the country till winter, and then retire also to the waters for their winter life; but they usually make themselves new lodgings every season. Mem. Acad. Par. 1732.

MUSK-*Seed*, in the materia medica, the name of the seed of the *alcea Ægyptiaca villosa*, or hoary Egyptian vervain mallow. It is a small seed of about the bigness of a pin's-head, of a greyish brown in colour, and of the shape of a kidney, and when it is fresh has a perfumed smell. It is brought into Europe from Ægypt, and from Martinico. The Ægyptians use it internally as a cordial and provocative; but in Europe it is of very little use, we wholly neglect it in medicine; but the perfumers in France and Italy use it among their compositions. *Lemery's* Dict. des Drog.

MUSKET (*Cycl.*)—MUSKET-*Baskets*, in fortification, baskets of about a foot and a half high, and eight or ten inches diameter at the bottom, and a full foot at the top. They are filled with earth, and set on low parapets or breast-works, or on such as are beaten down, that the musketeers may fire between them at the enemy, and yet be tolerably well secured against their fire.

MUSQUETEERS, *Mousquetaires*, in France, are troopers who fight sometimes on foot, sometimes on horseback; they are gentlemen of good families, and are divided into two troops, the one called the grey *Musqueteers*, because of the colour of their horses; the other the black *Musqueteers*, for the same reason.

MUSSAHIR, in ornithology, a bird mentioned by Arabian writers. It is said, that this creature after having employed the day in seeking its food, spends the whole night in singing; its notes are said to be so melodious, as to banish all thoughts of sleep from them that hear them. *Hofm.* Lex. Univ. in voc.

MUST (*Cycl.*)—MUST *of Rhenish wine*. This is a liquor that, though drank by some, is found extremely to affect the brain; for not having passed the natural effervescence which it would have been subject to, in the making of wine, its salts are locked up till the heat of the stomach setting them to work, they raise their effervescence there, and send up abundance of subtile vapours to the brain. The *Rhenish Must* is of two kinds, being made either with or without boiling. That made without boiling is only put up so close in the vessel, that it cannot work; this is called stumm-wine. That by boiling is thus prepared: they take strong vessels not quite filled, and putting them into a cellar they make a fire mild at first, but increased by degrees; and afterwards they gradually lessen it again, that the boiling may cease of itself. This operation is finished in thirty-six or forty hours, according to the size of the vessel; and the wine-boilers, instead of common candles which would melt by the heat, use thin pieces of split beach-wood. These also serve for a double purpose, not only lighting them, but giving them notice of the boiling being enough; before that time, the quantity of vapours thrown up make them burn dim; but as soon as it is finished, the vapours ascend in less quantity, and the lights burn brisk and clear. About seven or eight days after this boiling, the *Must* begins to work, and after this working it is called wine. They have also another kind of *Rhenish Must*, which is thus prepared: they boil the liquor to half the quantity, and put into it the medicinal ingredients they are most fond of; such as orange-peel, elecampane-root, and juniper-berries, or the like; being thus medicated, the whole works much more slowly, than it otherwise would. If the boiled *Must* by too violent an effervescence cast out its lees, it will on this become vapid and dead, unless this separation is stopped by some fatty substance, such as fresh butter, or the like: They put this in upon a vine-leaf, or else apply lard to the mouth of the vessel. *Portzius*, de Vin. Rhen.

MUSTACEUM, among the antient Romans, a kind of cheese-cake. It was composed of cheese, anniseed, cumin, and suet added to flour, moistened with *mustum*, or new wine. *Pitisc.* in voc. See the article MUST, *Cycl.* and *Suppl.*

MUSTARD, *Sinapi*, in botany. See the article SINAPI.

The common *Mustard* is cultivated in many places, both in gardens and fields, for its seeds. It is propagated by sowing the seeds in spring upon an open place, which has been well dug or ploughed. When the young plants are come up they must be cleared of weeds, and houghed up to about eight or ten inches asunder. They will then grow strong, and when the seeds ripen the whole plant is cut down, and the seeds thrashed out.

But besides this, there is another kind of *Mustard*, commonly known by the name of the white or garden *Mustard*, which is sown for a sallad-herb in spring: the seeds of this are to be sown very thick in drills on a warm border, or a moderate hot bed; they will be fit to cut for sallading in three weeks after the sowing. *Miller's* Gardener's Dict.

Hedge-MUSTARD, *Erysimum*, in botany. See the article ERYSIMUM.

MUSTARD *Vomits*. The powder of *Mustard*-seed may be made into the consistence of a loch with warm water, in which a little sea-salt has been dissolved. Of this a common spoonful, sometimes two, diluted with tepid water, are given on an empty stomach; it operates well as an emetic, and proves an excellent remedy in most nervous disorders, according to Mr. Monro, in Med. Ess. Edinb. Vol. 2. Art. 19. p. 303. not.

MUSTELA, the *Weasel*, in the Linnæan system of zoology, is a distinct genus of quadrupeds, including the ferret, pole-cat, martin, ermin, *&c.* The characters of the genus are, that the creatures of it have a considerable number of paps situated on the belly, feet adapted to climbing, and four *dentes molares* or grinders, on each side of the mouth. See Tab. of Quadrupeds, N°. 24. and *Linnæi* Syst. Nat. p. 36.

The *Weasel*, in some parts of England, is called the *foumart*, or *fitchet*. It is a little creature, smaller than the *pole-cat*; its back and sides are reddish, and its throat and belly white, the whiteness reaching perfectly from the angle of the chin to the insertion of the tail: Its head is something like a dog's, the upper jaw reaches beyond the lower, and is ornamented with some bristles by way of whiskers. Its fore-teeth are six in number in each jaw, and are small and set very close together, like the teeth of a comb; those of the under jaw are much smaller than the others; the dog-teeth are long, large, and strong; the eyes are small and black, the ears short and broad, and covered with very thick-set hairs; and, which is a very remarkable circumstance, they are doubled in their lower part. The inner cavity of the ear is very large, and full of tubercles. The feet are small, but broad, and each divided into five toes; the legs are short. The heart and liver are, in dissecting this creature, found remarkably large. *Ray's* Syn. Quad. p. 195.

MUSTELA *Africana*, in zoology, a name by which Clusius has called an animal, properly of the squirrel kind, and known among others by the name of the Barbary squirrel. *Ray's* Syn. Quad. p. 218. See the article SCIURUS.

MUSTELA, in ichthyology, the name of a genus of fishes, of which there are several species; the most common of which is that called the *Sea-loche*, or whistle-fish. This resembles the common eel in figure, colour, and slipperyness to the touch; but it is not half so long, in proportion to its thickness; and is something flatter, and has a turgid belly. It is covered with extremely minute scales, and its mouth is large, and furnished with sharp teeth, and has several series of very small teeth in many parts of its mouth. At the angle of the lower jaw it has one beard, and at the upper part of the nostrils in the upper jaw it has two. It has two pair of fins under its belly, and on the back, beside the common fin reaching half the length and almost to the tail, it has at some small distance from the head a cavity in which is a membrane edged with filaments.

The different species of this fish are of three colours; one is not spotted, and of the colour of a tench; another is spotted with white; and the third with reddish black spots; and beside these there are the *Mustela vivipara* of Schonfeldt, commonly known by the name of *Aelquappe*, and the *Mustela fossilis*, called *Peisker*, and the *Eel-pout*. *Willughby's* Hist. Pisc. p. 121. All which see under their several heads.

MUSTELA *Fluviatilis*, in ichthyology, a name by which several authors have called the common *lampetra* or *lamprey*. *Bellon.* de Pisc. 1. p. 91. *Gesner*, de Pisc. p. 696.

MUSTELA *Lumpen*, in ichthyology, a name given by Artedi, from Ray and others, to that species of blennus called simply *lumpen* at Antwerp; and by Gesner *galea*.

It is distinguished by Artedi from the other blenni, by a specific name expressing that it has four bifid cirri or beards growing under the throat, and transverse areolæ or streaks on the back. See the article BLENNUS.

MUSTELA *Marina*, in ichthyology, a name given by Bellonius and others to that fish which we call in English the *sheat-fish*, the *glanus* and *glanis* of Pliny and the old authors.

It is distinguished by Artedi by the name of the *silurus*, with four beards near the mouth. By this character it is evidently distinguished from the fish called the *lake*, which, though a genuine species of silurus, has only one beard.

MUSTELINUM *Genus*, in zoology, the name of a class of animals, so called from their general likeness to the weasel in shape; they are all carnivorous animals, and are distinguished from the other quadrupeds of that sort by their smallness, the length of their bodies, and the smallness and narrowness of their heads. Their feet are small, and their legs short, whence they are calculated for running into holes and crannies; their teeth are less numerous than in many quadrupeds; in the dog kind there are forty, and in these but thirty-two. Their intestines are short and simple; they have no colon nor cæcum, nor any distinction of great and small guts. *Ray*'s Syn. Quad. p. 195.

MUSTELUS, in ichthyology, a name given by Gaza and some other writers, to the fish called *galeus asterias*, and *stellatus* by modern authors. This only accidentally differs from the common *galeus lævis*, the smooth or unprickly hound. Both are accounted the same species by Artedi, and are expressed by the same name, the *squalus* with obtuse or granulous teeth. See the article SQUALUS.

MUSTELUS *Lævis*, a name by which Aldrovandus and some others have called the fish, distinguished by others by the name of *galeus lævis*, the smooth hound-fish. *Aldrov.* de Pisc. p. 393. See the article GALEUS.

MUSTELUS *Lævis*, in zoology, the name of a kind of shark, called also the *canis galeus*, and *canosa*. *Willughby*'s Hist. Pisc. p. 51. See the article CANIS *Galeus*.

MUSTUS *Fluviatilis*, in ichthyology, a name given by Bellonius to that species of cyprinus which we know by the name of the barbel. See the article CYPRINUS.

MUSTUS is also a word used by some authors to express the white calx of urine.

MUTABILIS *Lapis*, in natural history, a name given by some to the semi-pellucid gem, more commonly called *oculus mundi*. See the article OCULUS *Mundi*.

MUTATIONES, among the Romans, post stages, or places where the public couriers were supplied with fresh horses.

The *Mutationes* were wholly designed for the use of these couriers, or messengers of state; in which respect they differed from *mansiones*. See the article MANSIONES.

MUTCHKIN, a liquid measure used in Scotland; it contains four gills, and is the fourth part of the Scotch pint. See the articles PINT, MEASURE, &c.

MUTEFERRIRA, a body of horse kept up in Egypt, in the service of the Grand Seignior; these, with the chaouses, were originally the guards of the sultans of Egypt. This is a body of the greatest dignity, as is expressed by the word, which signifies a chosen people. *Pocock*'s Egypt, p. 166.

MUTILUS, in natural history, the name given by some to the common muscle. See the article MYTULUS.

MUTU, in zoology, a name by which some call a large Brasilian bird, of the gallinaceous kind, more usually called *mitu*. *Marggrave*'s Hist. Bras. See the article MITU.

MUZZLE (*Cycl.*)—MUZZLE *of a Gun or Mortar*, the extremity of the cylinder, where the powder and ball is put in. The metal which surrounds the extremity of the cylinder, is likewise called the *Muzzle*.

MYAGRUM, in botany, the name of a genus of plants, the characters of which are these: The flower consists of four leaves, and is of the cruciform kind; and the pistil which arises from the cup, becomes finally a fruit of a turbinated form, unicapsular, and containing one oblong seed, and having two empty cells at the apex.

The species of *Myagrum*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved single-seeded *Myagrum*. And 2. The lesser single-seeded *Myagrum*. *Tourn.* Inst. p. 211.

MYAGRUS *Deus*, in the antient mythology, a name given to Jupiter on certain occasions, as when they sacrificed to him at the olympic games, to drive away the vast quantities of flies which usually infested those rites. The word, though it stands thus in Pliny, and many of the old authors, is yet falsely printed, for this *Myagrus* signifies the mouse-destroyer, not the fly-destroyer, which is properly signified by *Myiagrus*. V. *Apomyos*, supr. and *Myiagrus*, inf.

MYCETITES, in natural history, the name of a species of sea-coral, which is usually of a conic shape and striated texture; always small, and usually found adhering to sea-shells, or large corals. See the article FUNGITÆ.

MYCETITES *Discoides*, in natural history, a name given by Dr. Woodward to those kinds of fossile coralloide bodies which the generality of writers had called, after Dr. Plot, *porpitæ*. These are usually small, and of a roundish, but flatted figure. They are hollowed on one side with a sort of umbilicus, and striated on the other. They are found on the ploughed lands in Oxfordshire, and some other of our midland counties, and in other places buried in the solid strata of stone. They are sometimes yellowish, sometimes brownish, and are from the breadth of an inch to a fourth part or less of that size. When broken, they are usually found to consist of a kind of spar, not unlike that of which the shelly coats of the echinitæ, or the lapides indici, and other spines of echini consist in their fossile state. And in some of them the ridges and striæ are thick set with little knobs and tubercles. The basis in some of these is flat, as it is in others rising in form of a circular elevation from the umbilicus, and others have a circular cavity in the same place. See Tab. of Fossils, Class. 7. *Woodward*, Cat. Foss. vol. 1. p. 114.

MYCONOIDE, an epithet used by some chirurgical writers for some ulcers which are found continually filled with a thick mucous matter.

MYDESIS, a word used by the antient physicians to express a general corruption of any part, from a great redundance of moisture. Galen has appropriated it to the eye-lids.

MYDRIASIS, a name used by authors to express a disease of the eye, consisting in a dilatation of the pupil, and a consequent dimness of sight.

MYDROS, a word used by Hippocrates to express a ball of iron or stone, which was used to be heated in the fire, and thrown into urine, intended as a fomentation.

MYGBAOTH, in the Jewish antiquities, a kind of mitre worn by the priests. See the article CIDARIS.

MYGDONIUM *Marmor*, a name given by the antients to a species of marble much used in their larger buildings. It was white, variegated with black; but that black rather disposed in clouds and spots than veins. It is confounded with the *docimenum marmor* by some writers; but that was always of a pure white, without the least variegation.

MYIAGRUS *Deus*, in the heathen mythology, a name given sometimes to Jupiter, and sometimes to Hercules, on occasion of their being sacrificed to for the driving away the vast numbers of flies which infested the sacrifices on certain public occasions. The word is generally spelt *Myagrus*; but this must be an error, as this word does not express the fly-destroyer, but the mouse-destroyer; and we have it sufficiently testified by the antients, that flies were the only creatures against whom this deity was invoked. Pliny calls this deity also *Myiodes*, and tells us, that the flies which used to pester the Olympic rites went away in whole clouds, on the sacrificing a bull to this god. We find in Athenæus also, that this sacrificing to the god of flies, at the Olympic games, was a constant custom. Some distinguish these two deities, and tell us, that the latter, or *Myiodes*, used to visit the nations in vengeance with a vast multitude of flies; and that, on paying him the due honours of a sacrifice, they all went away again; and this seems to agree with what Pliny tells us in some places. See the article MYIODES.

At the time of the Olympic games, Jupiter was worshipped under the name of the *Apomyos*, or *Myiagrus Deus*, to supplicate the destruction of those troublesome creatures. This happened only once in many years, when the sacrifices were performed there; but the Elians worshipped him continually under this name, to deprecate the vengeance of heaven, which usually sent, as they expressed it, an army of flies, and other insects, toward the latter end of the summer, that infested the whole country with sicknesss and pestilence.

MYIODES *Deus*, in the heathen mythology, a name given sometimes to Hercules, but more frequently to Jupiter, to whom a bull was sacrificed, in order to make him propitious in driving away the flies that infested the Olympic games. See the article MYIAGRUS *Deus*, supra.

MYLASSENSE *Marmor*, in the works of the antients, a name used for a species of marble, dug near a city of that name in Caria. It was of a black colour, but with an admixture of purple; the purple not disposed in veins, but diffused through the whole mass. It was much used in building among the Romans.

MYLE, a word used by some authors as a name for the *patella* or *limpit*, and by others to express what we call a mole, or false conception in the uterus.

MYLO-HYOIDÆUS, a broad thin penniform muscle, situated transversely between the internal lateral parts of the basis of the lower jaw, and lying on the anterior portions of the two digastric muscles. It is made up of two equal fleshy portions, one lying on the right side, the other on the left, both on the same plane, and joined to a small middle tendon, which is inserted anteriorly in the middle of the basis of the os hyoides, and from thence runs directly forward, diminishing gradually in its course. This is therefore a true digastric muscle, and cannot be divided into two. Each portion is fixed by

by fleshy fibres to the internal lateral part of the lower jaw, between the oblique prominent line and the basis under the first four *dentes molares* and the *caninus*; the anterior and greatest part of the other fibres of each portion run obliquely from before, backward to the middle tendon, in which they are regularly fixed, the anterior fibres being the shortest, and a small triangular void space being formed between them and the symphysis of the chin. The posterior fibres of each portion, which make about a fourth part of the whole, run likewise on each side of the os hyoides, and are inserted along the lower edge of its anterior or convex side, and from thence a little upward. *Winslow's* Anatomy, p. 254.

It has its name from the os hyoides, and the Greek μύλαι, the dentes molares.

MYLON, in surgery, is used for the largest tumours of the staphylomatous kind in the cornea and uvea of the eyes. *Heister's* Surgery, p. 423. See the article STAPHYLOMA.

MYOCEPHALUS, a name given by some authors to the distemperature of the eyes, commonly known by the name of a staphyloma. *Heister's* Surgery, p. 423.

MYODES *Platysma*, a name given by some anatomical writers to what is called by others the quadratus genæ; it is a muscular expansion in the neck.

MYOPARO, among the Romans, a kind of ship, which partly resembled a merchant-ship, and partly a ship of war, and was that which pirates mostly used. *Pitisc.* in voc.

MYOPIA. See the article SHORT-SIGHTEDNESS.

MYOPS, *Fly-eyed*, a word used to express a person who is short-sighted or pore-blind.

MYOPS, in natural history, the *Ox Fly*, an insect usually confounded with the breeze fly, but really differing very much from it. This is common in woods and about path-ways, and never fixes on any other creatures except oxen. It has a long and somewhat flat body, and is of a blackish grey in colour.

MYOSOTIS, *Mouse-Ear*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, consisting of several leaves ranged in a circular order. The pistil, which arises from the cup, becomes at length a seed-vessel, of the shape of a bull's horn, open at the end, and containing small roundish seeds affixed to a placenta.

The species of *Myosotis*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved Alpine *Myosotis*. 2. The woolly *Myosotis*, with broad leaves, resembling those of toad-flax. 3. The woolly *Myosotis*, with narrower toad-flax leaves. 4. The hoary creeping *Myosotis*. 5. The Spanish corn *Myosotis*. 6. The hairy field *Myosotis*, with large flowers. 7. The hairy field *Myosotis* with small flowers. 8. The clammy and hairy field *Myosotis*. 9. The smaller hairy *Myosotis*. 10. The knot-grass-leaved field *Myosotis*. 11. The narrow-leaved woolly and viscous Alpine *Myosotis*. 12. The low myrtle-leaved Alpine *Myosotis*. 13. The *Myosotis* with very fine ridged leaves. 14. The large-flowered Portugal *Myosotis*, with toad-flax leaves. *Tourn.* Inst. p. 244.

In the Linnæan system of botany, the characters of the *Myosotis* are these: The cup is an oblong erect perianthium, slightly divided into five segments at the extremity, and remaining when the flower is fallen. The flower is composed of only one petal, in form of a cylindric tube, short, and slightly divided into five at the extremity; the jags being rimmed round, and obtuse; and the opening of the flower closed by five convex prominent scales. The stamina are five very short filaments, placed in the neck of the tube. The antheræ are small, and covered. The pistil has four germina. The style is slender, and of the length of the tube of the flower. The stigma is obtuse. The cup remains, and holds four oval seeds. *Linnæi* Gen. Plant. p. 56.

MYRACOPON, a name used by some authors for an ointment intended to be used to the whole body to prevent lassitude. It is described by Galen.

MYRICA, in botany, a name by which some authors call the plant tamarisk. *Chabræus*, p. 75.

MYRINX, a word used by some to express the membrane of the tympanum in the ear.

MYRIOPHYLLUM, in botany, the name of a genus of plants, called by others, *pentapterophyllum*. The characters are these: It produces both male and female flowers distinct on the same plant. In the male flower the perianthium is composed of four oblong and erect leaves; the exterior one being large, the interior one much smaller. There is no corolla. The stamina are eight capillary filaments, which are longer than the cup. These are of a loose flaccid structure. The antheræ are oblong. The female flowers always stand below the male. The perianthium is divided into a number of segments. The pistil has four germina of an oblong figure. There are no styles; but the stigmata are hoary. The seeds are placed four together, and are of an oblong figure. *Linnæi* Gen. Plant. p. 459. *Ponteder.* Anth. 18. *Vaillant*, Act. Germ. 1719. *Dillen.* Gen. 7.

MYRMECIAS *Lapis*, the *Wart Stone*, a name given by some authors to a stone covered on the surface with wart-like excrescences. It is a name of a very vague signification, some of the stones called by it being mere flints, and others owing their protuberances to coralloide bodies, the wires of asteriæ, or other of the extraneous fossils contained in them, and so lodged, that their ends just stand out.

MYRMECITES, in natural history, a name given by some authors to a small stone, with some imaginary resemblance of an ant in its shape. Others have also made it the name of such pieces of amber as contain an ant, or the legs, wings, or other fragment or remains of that little animal.

MYRMECOPHAGA, the *Ant-Eater*, the name given by Linnæus to the creature called by others, the *tamandua-guacu*, or ant-bear.

The name is derived from the Greek μυρμὴξ, an ant, and φάγω, to eat. The creature is so called because his food is ants, which he eats by thrusting his long tongue into their nests, and drawing it back into his mouth when covered with them.

This, in the Linnæan system of zoology, is a distinct genus of animals, the characters of which are, that they have no teeth; have feet formed not for climbing, but walking, and have eight abdominal paps, six on the belly, and two on the breast. *Linnæi* Syst. Nat. p. 34.

MYRMILLO, among the Romans, a kind of gallic armour used in theatrical shews. But some will have it to be the same that Achilles's *myrmidones* wore; whence it had this name. *Pitisc.* in voc.

MYROBALANS (*Cycl.*)—It is very evident from the writings of the antient Greeks, that what we at this time call the *Myrobalan* was not known to them under that name, and perhaps what they called so is not known to us at this time; our *Myrobalans* being a sort of plums, and theirs being a dry fruit, rather of the nut-kind, and used in perfumed unguents, and other compositions of that kind, to give them a scent. This variation from the original sense of the word is not new, however, and the authors who began it are so far back, that it seems to have been an error of as old a date as any of this kind.

MYROBATINDUM, in botany, a name given by Vaillant to a genus of plants, which, with the *camara* of Plumier, and the *pseudoviburnum* of Rivinus, is included by Linnæus under one general character, by the name *lantana*. *Vaillant*, Act. Germ. 1722. See the article LANTANA.

MYRRH (*Cycl.*)—It is an apophthegm of chemists, derived from Van Helmont, that whoever can make *Myrrh* soluble by the human body, has the secret of prolonging his days. And Boerhaave owns there seems to be truth in this from its resisting putrefaction. He himself, and other chemists before him, have given methods for making solutions of *Myrrh*, but only by means of alcohol. It seems not a little surprizing that such great chemists should never find out that *Myrrh* is soluble in common water. *Pemberton*, Lond. Disp.

MYRRHINA *Vasa*, in antiquity. See the articles MURRINE, and MORRHINA.

MYRRHIS, in botany, the name of a genus of umbelliferous plants, the characters of which are these: The flower is of the rosaceous kind, composed of several unequal petals, which are arranged in a circular order, on a cup which afterwards becomes a fruit, composed of two long seeds, resembling the beak of a bird, which are striated and gibbose on one side, and smooth and plain on the other.

The species of *Myrrhis*, enumerated by Mr. Tournefort, are these: 1. The greater *Myrrhis*, or sweet cicutaria. 2. The annual *Myrrhis*, with smooth striated seeds. 3. The little white-flowered perennial *Myrrhis*, with hairy leaves, and gold-coloured seeds. 4. The yellow perennial *Myrrhis* with daucus leaves. 5. The tuberous or knotty *Myrrhis*. 6. The hoary annual *Myrrhis*, with striated hairy seeds. 7. The broad leaved white flowered marsh *Myrrhis*. 8. The broad-leaved red-flowered marsh *Myrrhis*. 9. The long-seeded daucus-like mountain *Myrrhis*. 10. The hairy-seeded annual Portugal *Myrrhis*, with parsnep leaves. 11. The trifoliate Canada *Myrrhis*, looking like angelica, and called by some the trifoliate American angelica. *Tourn.* Inst. p. 315.

The seeds of the common sweet cicely, or wild chervil, are a very powerful diuretic and promoter of the menses. They are good in jaundices, and beginning dropsies, and in the gravel and stone.

MYRRHITES *Lapis*, in natural history, a name used by many of the antient authors for a semi-pellucid stone of the nature of the agates; and seeming to have been the yellow cornelian of the moderns.

MYRTIDANON, a word used by the old Greek writers on medicine, but in a different sense by different authors.

Hippocrates calls it a round fruit, which the Persians in his time called pepper, and which probably had all the heating qualities of that fruit. Dioscorides expresses it by an excrescence common on the trunk of the myrtle, and which, as he observes, is more astringent than the myrtle itself. *Myrtidanum vinum* also signified wine impregnated with myrtle.

MYRTIFORMIS *Nasi*, (*Cycl.*) in anatomy, a name given by Santorini, and some others, to one of the muscles of the face, called by Albinus, *depressor alæ nasi*, and by Cowper and others, *depressor labii superioris, constrictor alæ nasi*.

MYRTITES, the name of a composition in the antient pharmacy, made of fine honey, and the depurated juice of myrtle berries boiled up together to a consistence.

MYRTLE, *Myrtus*, in botany. See the articles MYRTUS, *infra*, and MYRTLE, *Cycl.*

There are feveral fpecies of this plant preferved in our gardens; they are all eafily propagated from cuttings. The beft feafon for this is July; and the ftraiteft and youngeft vigorous fhoots are to be chofen. Thefe fhould be cut off about eight inches long, and the leaves of the lower part ftripped off to two inches high, and that part of the ftalk twifted which is to be placed in the ground; they are to be planted in pots of light rich earth, at about two inches diftance from each other, obferving to clofe the earth very well about them, and give them a gentle watering. They are then to be removed into a moderate hot-bed, and fhaded and watered once in two or three days till they have taken root. In about a month's time they will be rooted, and will begin to fhoot, and muft then be inured by degrees, to the air; and in Auguft they fhould be removed into the open air, but placed in a warm fituation, and fheltered from the winds; they fhould ftand here till October, and then be removed into a green-houfe, where they fhould be placed fo as to have as much air as poffible. In the March following they fhould be removed into feparate pots of rich earth, and in May fet out to the open air in a warm and well defended place. They will require in the fummer frequent waterings, and the dead leaves fhould be carefully picked off. As they advance in growth, they are to be fhifted at times into pots of a larger fize; and this fhould be done either in April or in Auguft; and toward the end of October, they fhould always be removed into the green-houfe.

MYRTILLUS, in botany, a name by which fome authors have called the black whortle berries. The *vitis idæa angulofa* of other authors. *Dale*, Pharm. p. 294.

MYRTOCHEILIDES, a name given by fome authors to the nymphæ in the female pudenda.

MYRTUS, the *Myrtle*, in botany, the name of a genus of trees, the characters of which are thefe: The flower is of the rofaceous kind, and is compofed of feveral petals arranged in a circular form. The cup finally becomes a fruit or berry of the fhape of an olive, coronated at the end, divided into three cells, and containing kidney-fhaped feeds.

The fpecies of *Myrtle*, enumerated by Mr. Tournefort, are thefe: 1. The broad-leaved Roman *Myrtle*. 2. The broad-leaved Bœtic *Myrtle*, or the bay-leaved *Myrtle*. 3. The bay-leaved *Myrtles*, with leaves growing in clufters. 4. The broad-leaved Belgic *Myrtle*. 5. The common Italian *Myrtle*. 6. The common Italian *Myrtle* with white berries. 7. The narrow-leaved Bœtic *Myrtle*. 8. The wild *Myrtle* with very fharp-pointed leaves. 9. The *Myrtle* with very fmall fharp-pointed leaves. 10. The common fmall *Myrtle*. 11. The common fmall *Myrtle*, with leaves variegated with yellow. 12. The broad-leaved white-berried Spanifh *Myrtle*. *Tourn.* Inft. p. 640.

Myrtle-berries are efteemed cooling and aftringent. They are recommended in gonorrhœas, diarrhœas, dyfenteries, and hæmorrhages of all kinds; but feldom ufed by the faculty.

MYRTUS *Sylveftris*, the *wild Myrtle*, in botany, a name given by fome authors to the *rufcus*, or butcher's broom, from fome faint refemblance of its leaves to thofe of the *Myrtle*. *Ger.* Emac. Ind. 2. See the article RUSCUS.

MYRUS, in zoology, a kind of fea-ferpent, a fifh of the eel clafs, fuppofed by fome to be the male murœna, but erroneoufly. Its fnout is very long and fharp-pointed; its body black, flender, and round, without fcales, and free from fpots. The cavity for the gills is only one on each fide. Near the neck there are fome fmall yellow dots to be feen, while the creature is alive; but thefe are fcarce vifible after it is dead. Its flefh is tender and delicate. *Rondelet.* de Pifc. vol. 1. p. 340.

MYS, in ichthyology, a name given by Ælian, Appian, and many others, to the fifh called *caprifcus* by the later writers; the *capros* and *chærus* of others of the antients. See the article GOAT-*Fifh*.

MYSIA, Μυσια, in antiquity, a feftival in honour of Ceres. For the origin and ceremonies obferved in it, fee *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 415.

MYSTERY (*Cycl.*)—Mathematicians have been accufed of introducing *myfteries* into geometry, which ought to have none. See the Analift; and Mr. *Maclaurin*'s Fluxions in the Introduction, and in other places. See alfo the article PARADOX.

MYSTOCEROS, in ichthyology, a name given by Gefner and fome others to that fpecies of the filurus which we call the fheat-fifh. It is the glanus of Pliny, and the reft of the old authors; the filurus of Rondeletius and others. It is diftinguifhed by Artedi by the name of the filurus with four beards under the chin. It is plainly to be known from the fifh called the *lake*, by this character; that having only one beard, it is a genuine fpecies of filurus. See the article SILURUS.

MYSTRUM, among the antients, a liquid meafure, which was the fourth part of the cyathus.

It weighed about two drams and an half of oil; and of water or wine, two drams two fcruples. It was much about our fmall fpoonful. *Danet.* and *Pitifc.* in voc.

MYSTUS *Fluviatilis*, in zoology, a name by which fome writers, particularly Bellonius, have called the common *barbel*. *Willughby*, Hift. Pifc. p. 259. See the article BARBUS.

MYSTUS *Marinus*, the *Sea Barbel*, the name of a fifh caught in the Adriatic, and common in the markets of Venice.

It is of an oblong figure, and in colour of a filvery white, variegated on each fide with ten obliquely tranfverfe black lines. Its belly is very white. Its tail is forked, and its head long. Its back fin has part of its rays prickly, part foft to the touch. Its eyes are not large, and their irifes are yellow. Its lips are prominent, thick, and foft, and only ferrated in the place of teeth; but in the hinder part of its mouth it has feveral rows of fhort and large *molares* or grinders. Its fcales are large, and adhere firmly to the flefh. It is a very well tafted fifh. *Gefner*, de Pifc. p. 144.

MYSTUS *Niloticus*, in zoology, a name given by Bellonius to a fifh of the barbel kind, caught in the Nile. Its body is thick and fhort, and its belly very broad. It grows to fo large a fize as to weigh twenty pounds. Probably this may be no other than the common barbel growing to a larger fize, as we fee many fifh will in fome places more than others. *Bellonius*, de Pifc.

MYTACISM, Μυτακισμὸς, in rhetoric, the too frequent repetition of the letter M, thus *mammam ipfam amo, quafi meam animam*. *Voff.* Rhet. l. 4. p. 46.

MYTIS, a name ufed by fome writers to exprefs the black juice found in the mouth of the fepia or cuttle-fifh, with which it colours the water when in danger of being taken, and by this means often makes its efcape. It is alfo ufed by Hippocrates as the name of a fea-fifh different from the fepia.

MYTTOTON, a word ufed by the antients to exprefs a mixt fort of country food, made of garlic, onions, eggs, cheefe, oil, and vinegar. It was much eaten by the labouring people among the antients, and accounted a very wholefome difh.

MYTULUS, the *Mufcle*, in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe: It is a bivalve fhell, of an oblong form, ending in a point, and having its two extremities equal. It is fometimes fmooth, fometimes rough. In fome fpecies flat; in others elate; and in fome has the beak elate. The *Tellina* and *Pinna marina*, of each of which there are feveral fpecies, are properly of this genus.

The three words of *Mytulus*, *Mufculus*, and *Tellina*, may however be made of great ufe in the fubdiftinctions of the genus into certain feries.

In this fenfe the word *Mytulus* may exprefs all the large *Mufcles*, fuch as the *pinna marina*, and other *Mufcles*, which are remarkably much elevated in their fhape, and have pointed beaks. The word *Mufculus* may be ufed to fignify fuch *Mufcles* as are fmaller and more flat; and *Tellina* to exprefs, as it ufually does with authors, a bivalve fhell of the *Mufcle* kind, but thinner and tenderer, and of an oblong figure, but not pointed.

The hinge of thefe fhells is not in the center of the fhells, but toward one end, and they have ufually a kind of little beak at that part.

The *Tellinæ* are attached to the fhell by two ligaments; the *Mufcles* only by one.

The largeft kind of *Mytulus* we know, is the *Pinna marina*; of which fhell we have three kinds, one larger than the reft, which is red within; this often produces pearls, but they are nearly of the fame reddifh colour with the lining of the fhell. There have been found fhells of this fpecies fo large as that the pair have weighed fifteen pounds. The fmall *Pinna*, and the rough echinated *Pinna*, have their fhells thicker near the edge where they open, than at the cardo. Thefe *Pinnæ marinæ* have a fort of filaments iffuing from the body of the fifh, and faftening it to ftones, or any other fubftances. This the antients called *byffus*, and wrought it into gloves and other things of that kind; and in fome places it is to this day put to the fame ufe. The common *Mufcles* have the fame property of forming thefe threads; and Lifter has thence called them *fetiferæ*. The filk of thefe common *Mufcles* is greatly inferior to that of the *Pinna marina* in finenefs and beauty. The *Mufcles* hold themfelves in the fame place, by means of their threads. The *Pinna marina* fticks its fharp end into the mud or fand, and all the reft of the fhell remains at liberty to open in the water. Its filaments, which are propagated from the middle of its body, ferve to draw up the mud and fand about it, on occafion, to defend it againft the motion of the water in tempefts.

The fpecies of *Mufcles*, known at prefent, are thefe: Of the flat kind, which terminate in a point at one end, we have the following: 1. The great ftriated magellanic *Mufcle*. 2. The fmaller ftriated magellanic *Mufcle*. 3. The fmaller variegated magellanic *Mufcle*. 4. The fmooth *Mufcle*. 5. The moufe-throat *Mufcle*. 6. The date *Mufcle*. 7. The large rough *Mufcle*; this is commonly found covered with balani or center-fhells. 8. The fmaller rough *Mufcle*; this is frequently found covered with fea-worms. 9. The blue *Mufcle*, ftriated near the bottom; this is a very rare fhell. 10. The rofe-coloured

loured variegated *Mufcle*. 11. The grey ftriated *Mufcle*. 12. The great Newfoundland *Mufcle*. 13. The great Canada *Mufcle*.

Of thofe ufually known in cabinets, under the name of *Pinnæ marinæ*, we have the following: 1. The common great *pinna*, variegated with grey and red. 2. The fmaller whitifh aculeated *Pinna marina*. 3. The fmall reddifh aculeated *Pinna*. 4. The *Pinna* of the fhape of a ham, commonly called the *ham Pinna*. 5. The larger fpinning *Pinna*, called the *filk Pinna*, becaufe of the great quantity of filk which it fpins. 6. The fmaller *Pinna marina*, called *Pinna tridacna* by Rondeletius. 7. The *Pinnophylax*; this is a large fpecies, fo called by Rumphius, from its often affording a lodging to a fmall crab. 8. The duck-bill *Pinna*.

Of thofe *Mytuli*, which are of a more elate figure and equilateral, we have the following: 1. The white tender *Mufcle*; this, when polifhed, is kept in cabinets under the name of the filver fhell. 2. The black *Pholas Mufcle*. 3. The yellow *Pholas Mufcle*. 4. The light and thin *Mufcle*, open in every part with a trunk. 5. The lefs open *Mufcle*, with a trunk. 6. The dufky-coloured *Mufcle*, from the ifle of Papous; this, when its outer coat is polifhed off, makes a very beautiful figure, and is found to be liniated within the fhell with brown and bluifh fafciæ, and in this ftate is a remarkably elegant fhell. See Tab. of Shells, N°. 19.

Of the *Tellinæ*, which are oblong and flat fhells with equal extremities, we have the following fpecies: 1. The violet-coloured *Tellina*. 2. The violet *Tellina*, with four white zones. 3. The fmooth *Tellina*, elegantly variegated with pale red and white fafciæ. 4. The hairy *Tellina*, of the Mediterranean fea. 5. The larger hairy *Tellina*, of the ocean. 6. The Canada *Tellina*. 7. The *Tellina* of the Azores iflands. 8. The great Newfoundland *Tellina*. 9. The fmall Canada *Tellina*. 10. The Saint Savinian *Tellina*. This laft is often found polifhed in our cabinets, and then is very elegantly variegated with rofe-colour and a filvery white. Thefe are all the known *Tellinæ*, with equal extremities.

But of thofe which have the two ends unlike, we have the following fpecies: 1. The reddifh-beaked *Tellina*, refembling a furgeon's forceps. 2. The yellowifh forceps *Tellina*. 3. The *Tellina* of the fhape of a knife. 4. The long-beaked *Tellina*. 5. The rough *Tellina*, called the cat's-tongue *Tellina*. 6. The fafciated and radiated rofe-coloured *Tellina*. 7. The orange-coloured *Tellina*, doubled on one fide, and dentated at the edge. 8. The leaf *Tellina*; this greatly refembles the leaf of a tree. 9. The white granulated *Tellina*. 10. The reddifh tranfverfely ftriated *Tellina*. 11. The flatted and truncated *Tellina*. 12. The violet *Tellina*, with a ftriated apex. 13. The yellowifh *Tellina*, with a ftriated apex. 14. The reddifh *Tellina*; this is an elegant fhell, though little variegated. Hift. Nat. Eclair. p. 326.

The common fea *Mufcle* has, from its being always found faftened to the rocks, been fuppofed by many wholly incapable of progreffive motion; but this is an erroneous opinion. It is a common practice in France at fuch feafons of the year as do not afford fun enough to make falt, to throw the common fea *Mufcles*, which the fifhermen catch about the coafts, into the brine-pits. They have an opinion that this renders their flefh the more tender and delicate, as the rain which falls at thefe feafons makes the water of the pits much lefs falt than the common fea-water. The *Mufcles* are on this occafion thrown carelefsly in, in feveral different parts of the pits; yet, at whatever diftances they have been thrown in, the fifhermen when they go to take them out, always find them in a clufter together; and as there is no current of water in thefe places, nor any other power of motion which can have brought the *Mufcles* together, it feems very evident that they muft voluntarily have marched from the places where they were at firft, to have met thus together. This progreffive motion is wholly performed by means of what we call the tongue of the *Mufcle*, from its fhape; but, from its ufe in this cafe, appears rather to merit the name of a leg, or an arm, as by laying hold of any diftant fubftance, and then forcibly contracting itfelf again, it draws along the whole body of the fifh; the fame part, when it has moved the animal to a proper place, ferves alfo to fix it there, being the organ by which it fpins the threads which we call its beard, by which it is held to a rock, or to another *Mufcle*. The motion of the *Mufcle*, by means of this part, is juft the fame with that of a man laid flat on his belly, who would draw himfelf along by laying hold of any thing with one hand, and then drawing himfelf to it. Mem. Acad. Par. 1710.

Mufcles are well known to have a power of faftening themfelves very firmly either to ftones, or to one another's fhells, in a very ftrong and firm manner; but the method of doing this was not well underftood, till the obfervations of the accurate Mr. Reaumur explained it.

Every one who opens and examines a common *Mufcle* will find, that in the middle of the fifh there is placed a little blackifh or brownifh body refembling a tongue; this in large *Mufcles* is near half an inch long, and a little more than a fixth of an inch in breadth, and is narrower at the origin than at the extremity; from the root of this tongue, or that part of it which is faftened to the body of the fifh, there are produced a great number of threads, which when fixed to any folid fubftance hold the *Mufcle* firmly in its place: Thefe threads are ufually from an inch to two inches in length, and in thicknefs from that of a hair to that of a hog's briftle. They iffue out of the fhell in that part where it naturally opens, and fix themfelves to any thing that lies in their way, to ftones, to fragments of fhells, or, which is the moft common cafe, to the fhells of other *Mufcles*; whence it happens that there are ufually fuch large parcels of *Mufcles* found together. Thefe threads are expanded on every fide, and are ufually very numerous, an hundred and fifty having been found iffuing from one fhell; they ferve the office of fo many cables, and each pulling in its proper direction, they keep the *Mufcle* fixed againft any force that can be offered from whatever part it come. The filaments are well known to all who eat *Mufcles*, who ever carefully feparate them under the name of the beard; and Mr. Reaumur has found, that while the animal is living in the fea, if they are all torn away by any accident the creature has a power of fubftituting others in their room: He found that if a quantity of *Mufcles* were detached from one another and put into a veffel of any kind, and in that plunged into the fea, they in a little time there faftened themfelves both to the fides of the veffel and to one another's fhells; the extremity of each thread feemed in this cafe to ferve in the manner of a hand to feize upon any thing that it would fix to, and the other part which was ftenderer and fmaller to do the office of an arm in conducting it.

To know the manner of the *Mufcle's* performing this operation, this diligent obferver put fome *Mufcles* into a veffel in his chamber, and covered them with fea-water; he there faw that they foon began to open their fhells, and each put forth that little body before defcribed by its refemblance to a tongue, and at the root of which thefe threads grow; they extended and fhortned this part feveral times, and thruft it out every way, often giving it not lefs than two inches in length, and trying before, behind, and on every fide with it, what were the proper places to fix their threads at: At the end of thefe trials they let it remain fixed for fome time on the fpot which they chofe for that purpofe, and then drawing it back into the fhell with great quicknefs, it was eafy to fee that they were then faftened by one of thefe threads to the fpot where it had before touched and remained fixed for a few minutes; and in repeating this workmanfhip the threads are increafed in number one at every time, and being fixed in different places they fuftain the fifh at reft againft any common force.

The feveral threads were found to be very different from one another, the new formed ones being ever whiter, more gloffy, and more tranfparent than the others; and it appeared on a clofe examination, that it was not as might have been moft naturally fuppofed, the office of the tongue to convey the old threads one by one to the new places where they were now to be fixed, but that thefe in reality were now become ufelefs; and that every thread we fee now formed, is a new one made at this time; and in fine, that nature has given to fome fea-fifhes, as well as to many land-infects, a power of fpinning thefe threads for their neceffary ufes. And that *Mufcles* and the like fifh are under water, what caterpillars and fpiders are at land. To be well affured of this, however, Mr. Reaumur cut off all the beard or old threads of a *Mufcle* as clofe as he could, without injuring the part, and the proof of the opinion of their fpinning new ones at pleafure was now brought to this eafy trial, whether thefe *Mufcles* fo deprived of their old ones could fix themfelves as foon as others which were poffeffed of theirs, and could throw out their threads to as confiderable diftances. The experiment proved the truth of the conjecture, for thofe whofe beards or old threads were cut off, fixed themfelves as foon as thofe in which they were left, and fpread their threads to as great a diftance every way.

When the mechanifm of this manufacture was thus far underftood, it became a natural defire to enquire into the nature of the part by which it was performed: This has hitherto been mentioned under the name of the tongue, from its fhape; but it is truly the arm of the fifh, and whenever it happens to be loofened from its company, or fixed in a wrong place, it ferves the animal to drag its whole body fhell and all along, and to perform its feveral motions. It fixes itfelf to fome folid body, and then ftrongly contracting its length, the whole fifh muft neceffarily follow it, and be pulled toward the place where it is fixed. This is an ufe however that this part is fo rarely put to, that it is not properly to be efteemed a leg or an arm, for this; but, according to its more frequent employment, may much better be denominated the organ by which the threads are fpun.

Though this body is flat in the manner of a tongue for the greater part of its length, it is however rounded or cylindric about the bafe or infertion, and it is much fmaller there than in any other part; there are feveral mufcular ligaments faftned to it about the root or bafe, which hold it firmly againft the middle of the back of the fhell; of thefe ligaments there are four, which are particularly obfervable, and which ferve to move the body in any direction. There runs all along this body a flit or crack, which pierces very deeply into its fubftance,

ſtance, and divides it as it were into two longitudinal ſections; this is properly a canal, and along this is thrown the liquor which ſerves to form the threads; and it is in this canal or ſlit that theſe threads are moulded into their form. Externally, this appears only a ſmall crack or ſlit, becauſe the two fleſhy ſections of the parts almoſt meet and cover it, but it is rounded and deep within, and is ſurrounded with circular fibres. This canal is carried regularly on from the tip of the tongue, as it is called, to its baſe, where it becomes cylindric; the cylinder in this part being no other than a cloſe tube or pipe, in which this open canal terminates. The cylindric tube contains a round oblong body, of the nature of the threads, except that it is much larger; and from the extremity of this all the threads are produced, this ſerving as a great cable to which all the other little cordages diſperſed towards different parts, are fixed. The tube or pipe in which this large thread is lodged, ſeems the reſervoir of the liquor of which the other threads are formed; all its internal ſurface being furniſhed with glands for its ſecretion. Mem. Acad. Par. 1711.

The *Muſcle*, like many other ſea-fiſhes, abounds in this liquor; and if at any time one touch with a finger the baſe of this ſpinning organ, one draws away with it a viſcous liquor in form of ſeveral threads, like thoſe of the caterpillar, ſpider, and the other ſpinning land-animals. The threads fix themſelves with equal eaſe to the moſt ſmooth and gloſſy, as to rougher bodies; if the *Muſcles* are kept in glaſs-jars of ſea-water, they as firmly faſten themſelves to the glaſs as to any other body.

Muſcles, be they ever ſo young, have this property of ſpinning; and by this means they faſten themſelves in vaſt numbers to any thing which they find in the ſea. Mr. Reaumur has ſeen them when as ſmall as millet-ſeeds, ſpin plentifully, though their threads proportioned to their own weight, are much finer and ſmaller than thoſe of larger *Muſcles*.

It is a queſtion yet undetermined whether the *Muſcle* has a power of breaking, or otherwiſe getting rid of its threads, in order to its removing from the place where it is once fixed; but it appears probable that they have not, and that they muſt remain where they have once faſtened themſelves, though their deſtruction be the conſequence of it. Mr. Reaumur tried this experiment in his jars, when they had well fixed themſelves to the ſides of them, he poured off part of the ſalt-water, ſo that it became the intereſt of the fiſh to leave their hold and go lower down, but they ſeemed to have no power to effect this. Mem. Acad. Par. 1711.

The common *Muſcle* affords the curious obſerver a very pleaſing object of examination by the microſcope. The tranſparent membrane, which immediately appears on opening the ſhell, ſhews the circulation of the blood for a long time together through an amazing number of veſſels. And Mr. Lewenhoek, in ſeveral which he diſſected, diſcovered numbers of eggs or embryo *Muſcles* in the ovarium, appearing as plainly as if he had ſeen them by the naked eye, and all lying with their ſharp ends faſtened to the ſtring of veſſels by which they received nouriſhment. The minute eggs, or embryos, are by the parent placed in due order, and in a very cloſe arrangement on the outſide of the ſhell, where by means of a gluey matter they adhere very faſt, and continually increaſe in ſize and ſtrength, till becoming perfect *Muſcles* they fall off and ſhift for themſelves, leaving the holes where they were placed behind them. *Baker*'s Microſcope, p. 242.

This abundance of *Muſcle* ſhells very plainly ſhew when examined by the microſcope, and ſometimes they are in the number of two or three thouſand on one ſhell; but it is not certain that theſe have been all fixed there by the *Muſcle* within; for theſe fiſh uſually lying in great numbers near one another the embryos of one are often affixed to the ſhell of another. The fringed edge of the *Muſcle*, which Mr. Lewenhoek calls the beard, has in every the minuteſt part of it ſuch variety of motions as is unconcievable; for being compoſed of longiſh fibres, each fibre has on both ſides a vaſt many moving particles. *Lewenhoek*'s Arcan. Nat.

MYUTES *Lapis*, in natural hiſtory, a name given by ſome authors to a foſſile body, part of an aſteropodium which they have thought in ſingle joints ſomewhat reſembled the ears of a mouſe. See the article ASTEROPODIUM.

MYXA, or MYXARIA, in the materia medica, a name uſed by ſome authors for the ſebeſtens, a ſort of plum of Ægypt and Aſia. *J. Bauhin*, V. 1. p. 198. See the article SEBESTEN, *Cycl.*

MYXOLYDIAN, in antient muſic, the firſt ſpecies of the diapaſon. See the article DIAPASON.

MYXON, in zoology, the name of a fiſh of the mullet kind, called by others, *Bacchus*.

It much reſembles the common mullet; but its head is leſs pointed, and its body is covered beſide the ſcales with a mucous matter. It has a remarkable irregularity in the manner of its ſwimming, and looks red about the lips and covering of the gills. *Rondelet.* de Piſc. p. 683. See the article MUGIL.

N.

NABATHÆA *filiqua*, in the materia medica, a name given by the interpreters of Avifenna, and other of the Arabian phyficians, to the *jembut*, or *aljembut*, of thofe authors.

It appears, from the accounts they have given us of this drug, that it was a long and flender pod, produced on a thorny tree. It has been generally fuppofed to be the fame wirh the *carob*, or *filiqua dulcis*, but very erroneoufly. The fame authors who mention this *aljembut*, or *Nabathæa filiqua*, mention that alfo under the name of the *alnabati*, or *Syrian filiqua*, as it is interpreted.

The *Syrian filiqua*, they fay, purges, and is good in colics. The *Nabathæan* they recommend to us, as an aftringent in hæmorrhages. It is plainly to be inferred from this, that the *Nabathæa filiqua* is different, in the greateft degree, from the Syrian pod, or *carob* fruit; and by its virtues, and the defcription they give us of the thorny tree which produces it, it feems very probable that it was the pod of fome fpecies of the *acacia*.

What gives the greateft probability to this opinion is, that the fame authors have plainly, in other places, called the *acacia* by the common name of *filiqua*. Ifidore, explaining fome paffages of the old Roman authors on this fubject, fays, that the fhrub *filicon*, which the Latins had improperly called *filiqua*, yields a fruit, the expreffed juice of which is the drug called *acacia* in the fhops.

The Arabian authors who mention this *filiqua Nabathæa*, and call it alfo *feuchi*, and *charnub feuchi*, defcribe the fhrub which produces it, as being prickly, and rifing but a cubit high from the ground; and, they add, that it had crooked, or falcated pods, which contained feeds, and a pulp very much refembling the other *filiqua*, which is the *carob*. Neophytus, and others, tell us, that the pods of the *acacia* were called by the Greeks *ceration*, as well as thofe of the *carob*; and the Arabians call the *acacia*, *alcarad*, a name plainly derived from this *ceration* of the Greeks.

As therefore both the pods of the *carob*, or *filiqua edulis*, and thofe of the *acacia* were called by the fame names *ceratia*, &c. it is plain that when the authors before-mentioned defcribe two kinds of *carob*, or as they exprefs it *ceratia*, differing from one another, and poffeffing, the one the virtues of the *carob* fruit, and the other of the *acacia*, they mean the *carob* by the purging fruit, and the *acacia* by the aftringent.

NABCA, in botany, a name by which fome authors have called the tree more ufually defcribed under the name of *œnoplia*, or the great jujube tree. *Chabræus*, p. 51.

NABECH, in botany, the name given by the Arabian writers to the fruit of the tree *fadar*, which is the *lotus* of Diofcorides, and the *acanthus* of Virgil. The fruit of this, which is round, and like a cherry, only fmaller, was firft called by this name *nabech*, or *nabac*, but afterwards the tree was alfo called by it. See the article SADAR.

NABLUM, in Hebrew, *nebel*, an inftrument of mufic among the Hebrews. The Seventy, and the Vulgate, tranflate it fometimes by *nablum*, and at other times by *pfalterion*, or *lyra*, or even *cithara*.

The *nablum* was a ftringed inftrument, very near of the form of a Δ, which was played upon by both hands, and with a kind of bow. See Calmet's differtation concerning the inftruments of mufic of the antient Hebrews, prefixed to the fecond volume of his commentary upon the pfalms. *Calmet*, Dict. Bibl.

NADIR-*il-kifne*, in the Turkifh offices, the fuperintendant over the wardrobe. *Pocock's* Egypt, p. 188.

NÆVI (*Cycl.*) are excrefcences of flefh in various parts of the body, fuppofed to have been occafioned by frights, difappointments, &c. of the mother, while the infant was in the womb. Thefe tumors arife in all parts of the body; they are of all figures, and of all fizes, and are fometimes of the common colour of the fkin, fometimes black, red, &c. Many of them, both in fhape and colour, refemble fruits of feveral kinds, as mulberries, ftrawberries, and the like; or animals, as mice, or fpiders.

They are to be removed, as warts, by ligature, cautery, or extirpation with the knife. But if they have large veffels near their roots, if they are ftrongly fixed to the bone, or if they feem to have a cancerous difpofition, it is much beft for the furgeon to let them wholly alone; and where they are feated in the neighbourhood of arteries, or large veins, if preffed to extirpate them, he fhould never be without cauteries, ftyptics, bandages, and other neceffary apparatus, in cafe of hæmorrhages. *Heifter's* Surgery. p. 323.

NAGEMULUS, in ichthyology, a name given by fome of the German authors to the fifh called by Willughby and others, the *lucioperca*, or *pike-pearch*. It is truly a fpecies of pearch, and is diftinguifhed from the common pearch, principally by having two long teeth on each fide of the mouth. See PERCA.

NAJAS, in botany, the name given by Linnæus to a genus of plants called by Vaillant and Micheli *fluvialis*. The characters are thefe: it produces male and female flowers diftinct. In the male flowers, the perianthium is compofed of one leaf of a cylindric figure, and truncated at the bafe, growing fmaller at the top, and having at the mouth two oppofite fegments which bend backwards. The flower is compofed of only one petal, and is a tube of the length of the cup; its verge is divided into four fegments, which are rolled backwards. There are no ftamina, but the middle of the flower produces one, oblong, erect anthera. In the female flower there is no cup, nor any petal, but a piftil whofe germen is of an oval figure, and terminates in a flender ftyle; the ftigmata are fimple; the fruit is an oval capfule, containing one oblong oval feed. *Linnæi* Gen. Pl. 443. *Vaill.* A. G. 1719. T. 1 T. 2. *Michel.* 8.

NAIL, (*Cycl.*) in the manege. The different pofition of the *nails* of the bridle, or left hand of the horfeman, gives the horfe a facility of changing hands, and forming his departure, and ftop; by reafon that the motion of the bridle follows fuch a pofition of the *nails*. To give a horfe head, you muft turn the *nails* downwards. To turn the horfe to the right, you muft turn them upwards, moving your hand to the right. To change to the left you muft turn the *nails* down, and bear to the left. To ftop the horfe you muft turn them upwards, and lift up, or raife your hand.

NAILS *of the human body*. Dr. Pozzi endeavours to prove, that the *nails* grow out of the tendons, which are fpread upon the laft phalanx of the fingers and toes. See UNGUIS.

NAKED *ftalk*, or *leaf*, among botanifts. See the articles STALK, and LEAF.

NAKIB, in the Oriental dignities, the name of an officer who is a deputy to the cadilifkier, or, as he may be called, the lord high chancellor of Egypt, appointed by the grand fignior. *Pocock's* Egypt, p. 170.

NAKIR, a word ufed by fome medical writers to exprefs a violent flatulence which paffes from one limb to another, and is always attended with pain.

NAKOUS, an Egyptian mufical inftrument, made like two plates of brafs, and of all fizes, from two inches to a foot in diameter; they hold them by ftrings faftened to their middles, and ftrike them together fo as to beat time. They are ufed in the Coptic churches, and in the Mahometan proceffions. *Pocock's* Egypt, p. 186.

NAL *la appella*, in botany, a name ufed in the Hortus Malabaricus to exprefs an Indian fhrub, or tree, from the roots of which they obtain an oil of a gold yellow colour, and very agreeable fmell, called *appel* oil. It is of a bitterifh and fharp tafte, and is in great efteem among them in pains of the head. Hort. Malab.

NAMANTIA, in ichthyology, a name given by the French to the *manati*, or *fea cow*

NAME (*Cycl.*) — *Generical* NAME. See GENERICAL.

NAMUR *marble*, a name given by our artificers to a fpecies of black marble, which is very hard, and capable of a good polifh, but has no variegations of any other colour. It is common in Italy, France, and Germany, and is the fpecies called the *Lucullean marble* by the Romans. *Hill's* Hift. Foff. p. 466. See LUCULLEUM *marmor*.

NAPELLUS (*Cycl.*) — This plant is poifonous in fome places, and innocent in others Its mortal quality increafes with the heat of the climate, and goes off where that is fmall. In the fouth of France, it is a fatal poifon; in Bretany, they find the roots inoffenfive to the moft tender conftitutions; and farther north, they eat the leaves among their fallad herbs, to get them an appetite, and find them a fafe and wholefome food. *Deflandes* Tr. Phyf.

It is faid the *napellus* may be fo corrected by volatile falt of tartar, as to become innocent. *Boyle's* Works, Abr. Vol. 1. p. 60. Dr. Hill makes the *napellus* a fpecies of aconite. *Hill's* Nat. Hift. Vol. 2. p 483.

NAPESCA, a name given by fome to a fpecies of *jujube*.

NAPHA, a name given by many of the writers in pharmacy to *orange-flower water*.

NAPHTHA, (*Cycl.*) in natural hiftory, the name of a genus of fluid foffils, the characters of which are, that they are of a thin confiftence, bright and pellucid, of a ftrong fmell, very readily inflammable, and, when pure, burning away, without leaving any refiduum.

Of this genus there are only two fpecies, the one commonly known by the name of *naphtha*, the other by that of *petroleum*. The firft is a pure and clear mineral fluid, of a much thinner confiftence than any of the expreffed oils of vegetables; and fome-

ſomething thicker than the finer of the diſtilled ones; it is of a pale yellow, with a faint caſt of brown among it, and is, indeed, of the very colour of the common brown amber uſed by the apothecaries. It is of a briſk, penetrating ſmell, ſomething like that of the chemical oil of amber, but not ſo offenſive. It is extremely inflammable, and is found floating on the waters of certain ſprings which break out at the ſides of hills in Perſia, Tartary, China, and other parts of the eaſt. It ſeems very practicable, by means of this mineral fluid, and a proper acid, to make a ſort of artificial amber, this being only a ſort of fluid amber.

The ſecond kind, commonly known by the name of *petroleum*, is a thin, ſubtle, and penetrating fluid, much thinner than the yellow *naphtha*, and as fine as the cleareſt diſtilled oils of vegetables. It is of a very ſtrong and penetrating ſmell; and is of various colours. It is naturally of a clear, fine, and bright white, and nearly as pellucid as the pureſt ſpring water; but it is more frequently found brown, rediſh, or blackiſh. It is produced in almoſt all parts of the world: England, France, and Germany, afford it in many places, but it is moſt plentifully found in Italy. *Hill's* Hiſt. of Foſſ. p. 419, ſeq.

Naphtha has much the ſame medical virtues with *petroleum*, only in a more remiſs degree. In Perſia, it is uſed externally on many occaſions, and alſo given inwardly in colics, a few drops being the doſe. See PETROLEUM.

NAPLES *yellow*, the common name in the colour ſhops of London, and among our painters, for the ochre called *giallolino*. See GIALLOLINO.

NAPUS, *navew*, in botany, the name of a genus of plants, the characters of which are the ſame with thoſe of the turnep, and which ſcarce deſerves to be made a different genus from it, differing only in its general figure.

The ſpecies of *navew* enumerated by Mr. Tournefort are theſe: 1. The white-rooted, manured *navew*. 2. The yellow-rooted, manured *navew*. 3. The black-rooted, manured *navew*. 4. The largeſt-rooted, manured *navew*. And, 5. The wild *navew*. *Tourn.* Inſt. p. 229.

The ſeeds of *napus* are roundiſh, of a blackiſh colour, and of an acrid and biting taſte. They are accounted deterſive, inciſive, aperitive, and digeſtive, and ſaid to be good in malignant fevers, and the ſmall pox, and are an ingredient in the Venice treacle. The root of the plant is ſaid to be alſo good in coughs, aſthmas, and conſumptions.

Nape oil is made from the ſeed of the *napus ſylveſtris Lobelii*, often called *navette*, and the oil *navetta oil*. *Lemery's* Hiſt. of Drugs. See NAVETTE.

NAPUS, in natural hiſtory, a name given to a ſpecies of *voluta*, approaching to the nature of the famous admiral ſhell, and more commonly known by the name of the *falſe admiral*, or *baſtard admiral*. See ADMIRAL.

NAPUT, in botany, the name given by the Norwegians to a plant whoſe root is an excellent remedy for the colic. It grows plentifully in the northern parts of Norway, and is the conſtant remedy uſed by the miners for their colics, which are particularly ſevere. The taſte is ſaid to be agreeable, being at firſt chewing ſomewhat like a radiſh, but afterwards having the flavour of the garden angelica. Phil. Tranſ Nº 114.

NARCAPHTHON, in the materia medica, the name given by many to the bark called *caſcarilla*.

NARCE, ναρκη, a torpor, ſtupor, or dullneſs of ſenſation; uſed either for a natural ſtupidity, or for that ſtupefaction of the ſenſes brought on by medicines, to alleviate the violence of pains.

NARCISSITES, in natural hiſtory, a name given by ſome authors to a ſpecies of *aſteropodium* from its ſuppoſed reſemblance to the flowers of the narciſſus; others have called ſome of the coralloide fungufes by that name, and others a ſpecies of echinites of the pileated kind.

It is, however, a name that none of them have any title to, ſince the reſemblance will appear very ſmall when nicely conſidered.

NARCISSOLEUCOIUM, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the liliaceous kind, and is compoſed of ſix petals, ſometimes equal, ſometimes irregular in ſize, and is pendulous, and of a ſomewhat bell-faſhioned form. The cup of the flower becomes finally a fruit of a roundiſh figure, divided into three cells, and containing roundiſh ſeeds; to this alſo it is to be added, that the root is bulbous.

The ſpecies of *narciſſoleucoium* enumerated by Mr. Tournefort, are theſe: 1. The common *narciſſoleucoium*. 2. The *narciſſoleucoium* with a white expanded flower. 3. The many-flowered, late, meadow *narciſſoleucoium*. 4. The double, many-flowered, meadow *narciſſoleucoium*. 5. The greater, trifoliate *narciſſoleucoium*. 6. The leſſer, trifoliate *narciſſoleucoium*. 7. The blue-flowered, trifoliate *narciſſoleucoium*. 8. The broad leaved, autumnal *narciſſoleucoium*. 9. The capillaceous-leaved, autumnal *narciſſoleucoium*. 10. The capillaceous-leaved, vernal *narciſſoleucoium*. *Tourn.* Inſt. p. 387.

NARCISSUS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is liliaceous, conſiſting of one leaf made in a bell-like ſhape, and divided at the edge into ſix ſegments, ſurrounding its middle in manner of a crown. The cup grows out of a membranaceous huſk, and becomes at length a longiſh, or roundiſh fruit, ſomewhat approaching to a trigonal form; and opening, ſhews itſelf to be compoſed of three cells, which uſually contain roundiſh ſeeds. See Tab. 1. of Botany, Claſs 9.

The ſpecies of *narciſſus* enumerated by Mr. Tournefort are theſe: 1. The great, pale-flowered *narciſſus*, with hoary leaves. 2. The great, blueiſh, white-flowered *narciſſus*, with a deep, yellow, circle. 3. The white-flowered, ſcented *narciſſus*, with the circle of the flower yellow. 4. The ſnow white, ſweet-ſcented *narciſſus*, with a red circle. 5. The white *narciſſus*, with a yellow circle. 6. The great, white, ſweet-ſcented *narciſſus*. 7. The great, white, oriental *narciſſus*. 8. The middle, white, oriental *narciſſus*. 9. The white, oriental *narciſſus*, with a ſtarry cup. 10. The great, plain, white *narciſſus*. 11. The leſſer, plain, white *narciſſus*. 12. The ſnow-white *narciſſus*. 13. The ſmall-flowered, white *narciſſus*, with the ſmell of jaſmine. 14. The great, white, oriental *narciſſus*, with a yellow cup. 15. The middle, white, oriental *narciſſus*, with a yellow cup. 16. The leſſer, white, oriental *narciſſus*, with a yellow cup. 17. The white, oriental *narciſſus*, with a yellow, double cup. 18. The oriental *narciſſus*, with a round, gold, yellow cup. 19. The pale-flowered *narciſſus*, with a ſaffron-coloured middle. 20. The pale-flowered *narciſſus*, with a gold, yellow middle. 21. The many-flowered, white *narciſſus*, with a deep, yellow circle. 22. The *narciſſus*, with a purple middle. 23. The pale-flowered *narciſſus*, with a ſaffron-coloured middle. 24. The pale-flowered *narciſſus*, with a gold, yellow circle. 25. The white *narciſſus*, with reflex leaves, and a ſhort, gold yellow cup. 26. The elegant *narciſſus*, with double flowers, variegated with yellow, and ſaffron colour. 27. The ſtrong-ſcented, full-flowered *narciſſus*, with a yellow middle. 28. The very large flowered *narciſſus*, with a yellow middle. 29. The ſnow white, fine ſcented *narciſſus*, with a yellow cup. 30. The many-flowered, African, yellow *narciſſus*. 31. The many-flowered, Portugal, yellow *narciſſus*. 32. The great, many-flowered, Conſtantinople *narciſſus*, with double, greyiſh, white flowers. 33. The yellow, Conſtantinople *narciſſus*. 34. The narrow-leaved, all-yellow *narciſſus*. 35. The narrow-leaved, yellow *narciſſus*, with a large cup. 36. The great, white-flowered, narrow-leaved *narciſſus*. 37. The ſmaller, white-flowered, narrow-leaved *narciſſus*. 38. The pale-flowered, narrow-leaved *narciſſus*, with a deep, yellow cup. 39. The little, white *narciſſus*, with a beautiful, purple border. 40. The graſſy-leaved *narciſſus*, with a deep yellow middle. 41. The ruſh-leaved *narciſſus*, with yellow flowers, and long cups. 42. The ſmaller, yellow-flowered, ruſh-leaved *narciſſus*. 43. The ruſh-leaved *narciſſus*, with yellow, variegated flowers. 44. The ruſh-leaved *narciſſus*, with a pale flower, and a deep yellow cup. 45. The ruſh-leaved *narciſſus*, with a round, roſe-like flower. 46. The plain, white flowered, ruſh leaved *narciſſus*. 47. The ruſh-leaved *narciſſus*, with twiſted leaves, and with white flowers, and yellow cups. 48. The white, autumnal *narciſſus*. 49. The ſmalleſt, white, autumnal *narciſſus*. 50. The great, white flowered, broad-leaved *narciſſus*, with a ſhort, yellow cup. 51. The broad-leaved, pale-flowered *narciſſus*, with a large, gold-coloured cup, and a ſtriated ſtalk. 52. The broad-leaved *narciſſus*, with large, pale-coloured flowers, and a yellow cup. 53. The middle, white *narciſſus*, with a ſhort, yellow cup. 54. The great, pale, yellow *narciſſus*. 55. The yellowiſh *narciſſus*, with an hexangular tube. 56. The yellow *narciſſus*, with a round tube. 57. The white *narciſſus*, with a yellow tube. 58. The white *narciſſus*, with a yellow cup, and with the ſmell of the muſcari. 59. The white *narciſſus*, with an oblong, yellow cup. 60. The wild, pale-flowered *narciſſus*, with a yellow cup. 61. The great, all-yellow *narciſſus*, with a very long cup. 62. The plain, yellow *narciſſus*, with the leaves of the flower bent back. 63. The ſmall, plain, yellow *narciſſus*. 64. The white *narciſſus*, with a yellow cup. 65. The white *narciſſus*, with a yellow fimbria. 66. The ſmall, creeping, yellow *narciſſus*. 67. The white, narrow-leaved *narciſſus*, with an oblong cup, and a depending flower. 68. The mountain, ruſh-leaved *narciſſus*, with a yellow cup. 69. The mountain *narciſſus*, with a fimbriated flower. 70. The ſmalleſt, white, mountain, ruſhy-leaved *narciſſus*. 71. The mountain, ruſhy-leaved *narciſſus*, with a gold, yellow cup. 72. The coronated, mountain *narciſſus*. 73. The double-flowered, oriental *narciſſus*, with yellowiſh, white flowers. 74. The broad-leaved, white *narciſſus*, with the yellow middle. 75. The white *narciſſus*, with a double yellow corona. 76. The double, plain, yellow *narciſſus*. 77. The double, purple-middled *narciſſus*. 78. The double, ſnow-white *narciſſus*. 79. The Virginian, double, white *narciſſus*. 80. The double, yellow, wild *narciſſus*, without a cup. 81. The double *narciſſus*, with variegated flowers. 82. The yellow, wild *narciſſus*, with a double, or triple, yellow tube. 83. The paler, yellow, wild *narciſſus*, with a triple tube. 84. The yellow *narciſſus*, with a divided tube. 85. The double, yellow, broad-leaved *narciſſus*. 86. The double, anemone-like, gold-yellow, ruſh-leaved *narciſſus*. 87. The gold-yellow, double *narciſſus*. 88. The ſea *narciſſus*, called by many the little, white *ſquill*. 89. The purple-flowered, ſea *narciſſus*, 90. The liliaceous *narciſſus*. 91. The white-flowered, ſpring, American *narciſſus*. 92. The American *narciſſus*,

narcissus, with double white flowers, smelling like balsam of Peru. 93. The white *narcissus* of Ceylon, with a hexangular sweet-scented flower *Tourn.* Inst. p. 353, seq.

NARCOS, in ichthyology, a name given by Joannes Cuba, and other writers, to the *torpedo* or cramp-fish; a species of raia, distinguished by Artedi by the name of the *raia tota lævis*, the wholly smooth raia.

NARCOSIS, a stupefaction or insensible state, whether brought on by medicines, or happening from natural causes.

NARDINUM *unguentum*, *ointment of spikenard*, an ointment greatly celebrated among the antient writers in medicine. It seems to have been variously prepared, but always with a great number of aromatic ingredients, and always with *spikenard* for the basis.

Dioscorides says, that the *malabathrum*, or Indian leaf, was sometimes an ingredient in it, but that it was also sometimes made without it. It was generally, however, mix'd with the *oleum balaninum*, or *amphacinum*, inspissated with an addition of schænanth; and to increase its fragrancy there were added, costus, amomum, myrrh, and balm of Gilead.

The finest was accounted that which was of a thin consistence, and very fragrant smell. It was said to be attenuating and detersive, but somewhat acrimonious; and was sometimes, for particular uses, reduced to a solid consistence with resin. *Dioscorides*, l. 1. c. 35.

NARDUS, in the Linnæan system of botany, the name of a distinct genus of plants of the grass kind, the distinguishing characters of which are, that there is no calyx; that the flower is composed of two valves; the exterior is very slender, oblong, and ends in a beard or awn, and in some sort receives the other into a cavity in its fore part: the interior is small and strait, and is terminated by a much shorter awn. The stamina are three capillary filaments, shorter than the flower: the antheræ are oblong: the germen of the pistillum is oblong: the styles are two in number, capillary, and reflex and downy: the stigmata are simple. The flower continues firmly attached to the seed. The seed is single, long, strait, pointed at both ends, and narrower in its upper than in its under part. *Linnæi* Gen. Plant. p. 19. See SPIKENARD, *Cycl.*

NARDUS *rustica*, in botany, a name attributed by some authors to the *asarabacca*, and by others to the *baccharis monspeliensium*. *Dale*, Pharm. p. 79.

NARES *piscium*. The *nostrils* in fish are placed so very variously, and have so many differences in number, figure, situation and proportion, that they make a very essential series of characters, for the distinguishing the genera and species one from another. In regard to number; 1. Some fish have them not at all, as the petromyzum. 2. Many fish have one *nostril* on each side, placed in the manner of those of birds and quadrupeds, as the chonepterus, &c. 3. Many have them placed two on each side, as the cyprini, percæ, &c.

In regard to figure, they are, 1. In some round, as all four are in the gadi, and the two anterior ones in the conger, mackrell, &c. 2. Some are oval, as the posterior pair in the conger, &c. and, 3. Many are oblong.

As to their situation, they also differ much: 1. Some are placed very near the snout or rostrum, as the clupeæ; and the anterior tubulose foramina, in the conger or sea eel, are also of this kind. 2. In many kinds of fish they are placed near the eyes, as in the pike, the pearch, and the like: and, 3. In some they are placed as it were at a middle distance between the eyes and the end of the snout, as in the ammodytæ or sand eels, &c.

The *nares* of fish differ also in proportion: in those fishes which have two pairs of these holes, they are, 1. In some very near one another, so as almost to touch: they are thus placed in the cyprinus and clupeæ, &c. 2. They are placed at great distances, which is the case in the conger, the pearch, and many others. According to these variations, the *nostrils*, tho' a part in general very little attended to, yet become of notable use in the distinguishing the species. *Artedi's* Ichthyol.

NARIFUSORIA, a name given by authors to such medicines as were meant to be instilled into the nostrils, for disorders of the head and eyes.

NARINARI, the Brasilian name of a fish of the *aquila marina* kind, called by the Dutch *piilstert* and *sicle*.

It is very large and flat, and the figure of its body is nearly triangular, its sides or wings being very broad, and larger. The head is very large, and has a furrow down its middle: the mouth is somewhat triangular, but rounded at the corners. It has no teeth; but in the place of them, has a bone in the under part of its mouth, in the shape of a tongue, of four fingers long, and a finger and half broad, and a smaller bone of the same shape in the upper part: between these it crushes its prey. The under bone consists of seventeen small pieces, of the figure of the letter V. These are hard and firm, and are held together by cartilages, and under them are the same number of others, much more soft and spungy. The upper bone consists of fourteen pieces, which are each in like manner double, and joined to one another by cartilages. The body is usually a foot and a half long, and the tail four foot. Its flesh is finely flavoured. *Marggrave* Hist. Bras. p. 119.

The bones of this and the like fish's mouths, are the fossile *siliquastra*.

NARIS *externus alius*, in anatomy, a name given by Riolanus to one of the muscles of the nose, the use of which, he says, is to dilate the ala of the nose, without any elevation of the nose itself. It is called by Albinus the *compressor naris*, and by Winslow the *transversalis*, or *inferior nasi*. Cowper calls it the *elevator alæ nasi*, and Santorini the *transversus nasi*.

NARONICÆ *radix*, in the materia medica, a name given by some authors to the iris root. *Ger.* Emac Ind. 2. See IRIS.

NARROW, in the manege. A horse is said to *narrow*, when he does not take ground enough, or does not bear far enough out to the one hand or to the other. If your horse *narrows*, you must assist him with the inside rein, that is, you must carry your hand to the outside, and press him forward upon straight lines with the calves of your legs.

NARROW is also a term among bowlers. See BOWLING.

NARWAL, a name given to a fish of the whale kind, more frequently called the *sea-unicorn*. See UNICORN.

NASAMMONITES, in natural history, a name given by the antients to a stone, which Pliny describes to have been of a blood colour, variegated with veins of black. We know no stone which answers to this character at present, unless it be some of the agates, in a variegated state.

NASCALE, a sort of pessary, made of wool, cotton, or the like, and introduced into the vagina, after being impregnated with proper ingredients.

NASDA, a word used by some medical writers for *naphthæ*, and seemingly a corruption of that word.

NASITAS, a word used by some authors to express a speaking thro' the nose.

NASTOS, in botany, a name by which Clusius and some other authors have called the reed, of which the common walking canes are made, which is the *arundo farcta* of other writers. *Ger.* Herb. p. 34.

NASTURTIUM, *cresses*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of four leaves, and is of the cruciform kind: the pistil arises from the cup, and becomes a roundish flatted fruit, divided by an intermediate membrane into two cells, and containing usually a number of flat seeds. To these marks it is to be added, that the leaves of the *nasturtiums* are divided and cut into segments, by which it is at sight distinguished from the thlaspi.

The species of *nasturtium* enumerated by Mr. Tournefort, are these: 1. The common garden *cress*. 2. The curled-leav'd garden *cress*. 3. The narrow-leav'd garden *cress*, with more curled leaves. 4. The broad-leav'd garden *cress*. 5. The wild *cress*, called by some the umbellated *thlaspi*. 6. The lesser-podded wild *cress*, with finely-divided leaves. 7. The wild *cress*, with extremely fine divided leaves. 8. The oriental *nasturtium*, with the lower leaves like those of yarrow, and the upper ones like those of thorough wax. 9. The wild *cress*, with cristated pods. 10. The alpine *cress*, with finely-divided leaves. 11. The little spring *cress*, called by some the rock *cardamine*. 12. The little rock *cress*, with leaves like those of shepherd's purse. 13. The small procumbent spring *nasturtium*: and, 14. The little spring *nasturtium*, with leaves only at the root. *Tourn.* Inst. p. 213.

Water-cresses are frequently eaten in spring as a sallad. The whole plant is of a very acrid taste, and is a powerful attenuant and resolvent. It is recommended as a kind of specific in the scurvy, and is eaten in great quantities by many with that intent. It is good against all obstructions of the viscera, and consequently in jaundices, and other chronic diseases. It is also a powerful diuretic and promoter of the menses. People have pretended to preserve the virtues of this plant in waters, syrups, and conserves; but the best way of taking it is either to eat it as a sallad, or to drink its expressed juice singly, or mixed with that of the other antiscorbutic plants, as brooklime, &c. which is often done.

NASUS, in zoology, the name of a fresh-water fish, common in the Rhine, the Danube, and most of the large rivers in Germany, tho' unknown in England, and called by different authors the *simus*, *savetta*, and *platyrynchos*.

Its general size is between six and twelve inches in length. In shape and colour it much resembles our chub. Its belly and sides are of a silvery white, and the belly fins and the lower half of the tail are often a little reddish: its head is small, and has a black spot on its hinder part; its belly is flat, and somewhat broad, and its scales large; and its snout or nose stand out beyond the mouth, which is a singularity, and from which it had its name. Its mouth is very small; it has no teeth, and its skull is pellucid. It is a loose and insipid-tasted fish, and very full of bones. They spawn in May, at which time the males are rougher than at any other season, and have their heads speckled with white spots, like the English rudd. At this time also they swim together in immense shoals, and the fishermen have sometimes caught two or three thousand of them in one night. *Willughby's* Hist. Pisc. p. 251.

NATANT *leaf*, among botanists. See LEAF.

NATATIO, *swimming*, in ichthyology. The *swimming* of fishes in general is greatly assisted by their air bladder. Those kinds which have not this bladder, either have regular lungs, and contain air in them, as is the case in the cetaceous fishes; or they have remarkably thin and flat bodies, as the rays and thornbacks, and the pleuronecti; or remarkably long and flexous ones, as the petromyza; and by these means are capable of easy flexuous motions, which, with the help of the fins, thrust them any way at pleasure; tho' their bodies are not so nicely pois'd, as to the

weight

weight of the water, as those of such fish as have the assistance of these air-vessels. It has been supposed by some, that the motion of fish in the water depended principally upon the pectoral fins, but this is easily proved false by experiment; for if the pectoral fins of a fish are cut off, and it be again put into the water, it will be found to move forward or sideways, upward or downward, as well as it did when it had them on. If a fish be carefully observ'd, while *swimming* in a basin of clear water, it will be found not to keep these pectoral fins constantly expanded, but only to open them at such times as it would stop or change its course, this seeming to be their principal, if not their only use. The pectoral and ventral fins, in the common fishes of the cathetoplateous or compressed form, serve in the same manner in the keeping the fish still, and serve in scarce any other motion than that toward the bottom: so that this motion of the fish, which has been generally attributed to their fins, is almost wholly owing to their muscles, and to the equipoise of their air-bladder. That the use of the pectoral and ventral fins is to keep the fish steady and upright in the water, is evident from the consequences of their loss: if they are cut off, and the fish put again into the water, it cannot continue in its erect natural posture, but staggers about, and rolls from side to side. The fins of the back and anus are also of great use to the keeping the creature in its natural position, as is easily seen by cutting them off, and observing the motions of the fish afterwards.

Tho' a great deal depends on the motion of the muscles of the several parts of the body in the *swimming* of the fish, yet the tail, and those muscles which move the lower part of the body, to which it is affixed, are the great instruments by which their swift motions in the water are performed. The moving the tail, and that part of the body to which it adheres, backward and forward, or sideways any one way, throws the whole body of the fish strongly the contrary way; and even in *swimming* strait forward, the motion and direction are both greatly assisted by the vibrations of this part, as may be experienced in the motion of a boat, which when impelled forward, may be firmly guided by means of an oar held out at its stern, and moved in the water as occasion directs. The dorsal muscles, and those of the lower part of the body between the anus and tail, are the principal that are used in the motion of this part, and these are therefore the most useful to the fish in *swimming*. The muscles of the belly seem to have their principal use in the contracting the belly and the air-bladder. They have been supposed of use to move the belly fins; but there are too many of them for such a purpose, and these fins have each its peculiar muscle fully sufficient to the business. The use of the tail in *swimming* is easily seen, by cutting it off, and committing the fish to the water without it, in which case it is a most helpless creature. See AIR-*bladder*.

NATIVO *habendo*, in law, a writ directed to the sheriff, for a lord who claimed inheritance in any villain, when his villain was run away from him, for the apprehending and restoring him to the lord. Terms of Law.

NATIX, in natural history, a name given by some old writers to the *nerita*.

NATRIX, in botany, the name given by Rivinus to a genus of plants, nearly allied to the anonis, and comprehended with it in one genus by Linnæus, under the name of *anonis*. *Rivin.* vol. 4. p. 82. See REST-*harrow*.

NATRIX, in zoology, the name of the common or water snake, called also *torquata*, from the ring about its neck. It is much longer and larger than the viper, and is no water animal, properly speaking, but a land one, which being able to swim very well, often takes the water to hunt about for frogs, which are its principal food. It grows to be much longer and larger than the viper, and does not bring forth live young ones, but great numbers of eggs, which it lays in dunghills, to be hatched by the warmth of the place, or by the heat of the sun.

It is very common in bushy places, and near waters, and in winter finds holes in the banks of ditches, or about the roots of trees, where it lies torpid the whole winter. It has no poison, and may be safely taken up and played with, never so much as attempting to bite. It feeds on many small insects, sometimes on vegetable substances, and oftener on frogs, mice, &c.

Its back is of a sort of dusky earth colour, and its belly variegated with black and a bluish white, but near the head almost wholly white, having only a few small spots of black at the sides, the colour growing darker toward the end of the tail; and near the end, the middle part of all the scales are black, and their extremities only of a bluish white: the whole belly is covered with long parallel scales, placed transversely. The back and sides are covered with small scales, and are variegated with several streaks and spots of black: there are more than eighty transverse black lines running from the back to the sides; and beside these, two other rows of smaller, in form of spots, near the middle of the back. The head is covered with large scales of a duskier colour than those of the rest of the body, and the upper jaw is white on each side, with four or five slight lines of black running across it. Its chain is yellow, and is composed of two large spots of that colour, placed one on each side of the neck, or at each angle of the jaws, between which is placed a large triangular spot of a deep black, with its top directed toward the tail. It has none of those long canine teeth of the viper and other poisonous serpents, by means of which the poison is conveyed into the wound, but only two rows of small serrated teeth, destined by nature for no other use than eating its food.

It may not be judged improper to have been thus particular in the description of this species, as it is well to know what of the snake kind are, and what are not to be feared; and as the apothecaries and others, for want of these characters, often buy this common snake under the name of the viper. *Ray's* Syn. Anim. p. 335, 336.

NATRUM, or NATRON, (*Cycl.*) in natural history, the name of the *nitre* of the antients.

There have been various opinions about the *natrum* of the antients, and some have been of opinion, that our salt petre or nitre was the same substance; but this has been always discountenanced by the more judicious. Dr Hill, who had met with a salt from the same part of the world whence the antients had their *natrum*, and which answered to all the characters they have given of it, defines it to be a salt found sometimes pure, and sometimes fouled with earth, fermenting with acids, and forming flat oblong crystallizations, with four unequal sides, and two truncated ends. These were the characters of that salt, and these perfectly agree with the accounts we have of *nitre* in the earliest ages, tho' we have none sufficiently accurate to take them all in. And whatever may have been the opinion of some, that the *natrum* or *nitre* of the Hebrews was very early lost, a careful examination of the antients proves the contrary, and that this very salt was the *nitre* both of the Greeks and Romans, the *nitrum* and *aphronitrum* of Dioscorides, and the *nitrum* of Pliny. It is found in broad and flat masses of various sizes, but usually small, and when broken, are found to be composed of fasciculi or bundles of small fibres, of an oblong and flatted figure, and laid but loosely together.

It is naturally of a dusky white; but is sometimes found of a brown colour, and sometimes of a fine deep red. This is its purest state; but beside this, it is frequently found in form of powder mixed with dirt, and rising in little hillocks on the surface of the ground. It is of an acrimonious pungent taste, and is more like the alkaline salts produced by burning vegetables, than any of the native salts. It dissolves in a very small quantity of water, and ferments violently with aquafortis, or any other weaker acid menstruum.

It is found in great plenty in Sindy, a province in the inner part of Asia, and in many other parts of the east, and might be had in any quantities. Perhaps it would be worth considering as a branch of commerce, as it would supply the place of pot-ashes in the making soap and glass, as the same author has tried.

The characters recorded of the *nitre* of the antients are, 1. That it would ferment with vinegar; and, 2. That it had an abstersive quality. These we have from the scriptures: and the rest were, that it was of an acid taste; that it was found native in the eastern parts of the world; that it served in the place of soap, and that with sand it would make glass. All these properties this salt has; and it may be added, that no other native salt has them. *Hill's* Hist. of Foss. p. 386 to 389.

It is a very remarkable property of this salt, that tho' in itself an alkali, and fermenting very violently with acids in its native dry state, yet in solution it does not ferment with them at all. If indeed oil of vitriol, or some other acid, be added to the solution of *natrum* while turbid, that is, while some of the particles of the salt remain yet whole in it, the two liquors will ferment violently; but if the solution be set by till wholly clear, the same acid will cause no effervescence in it; but the same solution, evaporated to a third part, will again ferment with that or any other acid, the particles of the salt at that time being got together again, and meeting the acid as in their solid form.

This salt contains a volatile alkali, absorbed from the air, and embodied in it. Its other principle seems a marine salt, which it may receive either from the earth, or from salt springs or sea water, according to the different places where it is found.

Pliny tells us, that the *natrum* of Egypt was only found to be produced at those times of the year when the dews fell. And M. de la Chambre affirms, that in Egypt, three or four days before the Nile begins to overflow, there always falls a certain dew, which has a fermenting quality, and will leaven dough exposed to the air. At the time of the falling of this dew, the *natrum* pits grow full of that salt: and Vanslebius, Sands, and many others, join in affirming, that at this time the air becomes greatly more healthy; and tho' before the falling of this dew, or the inundation of the Nile, people die of the plague to the number of five hundred in a day in Grand Cairo, after this not one dies of that disease. It is easily seen, that the overflowing of the Nile does not produce this effect, but the dews and air, which at that time are full of that volatile alkali, which is one of the principles of the *natrum*. People who have preserved specimens of the *natrum* have also observed, that they would grow much heavier on being exposed to the air at the time of the overflowing of the Nile. Phil. Transf. N° 160.

NA-

NATURAL (*Cycl.*) — NATURAL *history*. The *natural history* only of any one particular place, is a subject very extensive in its materials, and to be set about without great care and circumspection. Mr. Boyle has favoured the world with a list of the heads under which to arrange things, and what to enquire after on such an occasion.

The general heads under which he comprehends the articles of this history, are four; the things which regard the heavens, the air, the waters, and the earth.

Of the first class are the longitude and latitude of the place; the length of the longest and shortest days and nights; the climates, parallels, &c. what fixed stars are seen, and what are not seen there.

About the air may be observ'd, its temperature, as to the first four qualities, and the measure of them; its weight, clearness, refractive power; its subtlety or coarseness; its abounding with or wanting an esurine salt: its variations according to the seasons of the year, and the times of the day: what duration the several kinds of weather usually have: what meteors it is most or least apt to breed; and in what order they are generated, and how long they generally last: what winds it is most subject to; whether any of them be stated or ordinary: what diseases are said to be epidemical, or depending on the state and condition of the air. what other disease it is subject to, wherein the air may be supposed to have some share: what is the usual salubrity and insalubrity of it, and what sorts of constitutions it agrees with, what it does not.

About the waters, it may be proper to observe the sea, its depth, tides, currents, saltness, and other qualities. next, the rivers will come under consideration, their depth, length, course, inundation, and the goodness or badness of their waters, with their gravity, and other peculiar qualities. After these, the lakes, springs, ponds, &c. are to be considered, especially the mineral waters, their kinds, qualities and virtues, and the manner of trying them. The inhabitants of the waters may follow here; and the particular kinds of fish that are found there, whether of the sea or rivers, are to be mentioned, with an account of their stores, bigness, goodness, seasons of perfection, haunts, peculiarities of any kind relating to them, and the manner of taking them, especially when there is any thing singular in it.

The things relating to the earth, are last to be examined: these are, first the earth itself, then its inhabitants, and its various productions, whether external or internal. In the earth itself may be observed, its dimensions, situation east, west, north and south; its figure; its plains and valleys, their extent; its hills and mountains, and the height of the tallest, both in reference to the neighbouring valleys and plains, and to the level of the sea; as also whether the mountains lie scattered, or are disposed in ridges; and if of the latter kind, whether they run east, west, north, or south. What promontories also, and what firey or smoaking hills it has, if any: whether the country be coherent, or much broken into islands: what the magnetical declination is in several places, and the variation of that declination in the same place, and if those be considerable; what may be conjectured as the occasions of them, whether the vicinity of iron-mines, of subterranean fires, or what else. What the nature of the soil is, whether clayey, sandy, or of good mold; and what vegetables, plants and trees best agree with it and succeed in it, what worst. By what particular contrivances the inhabitants improve the advantages, or remedy the disadvantages of the soil; and what hidden qualities the soil may have. The inhabitants of the earth are then to be considered, both natives, and strangers that have been long settled there; and in particular, their stature, colour, features, strength, agility, or defects of these; and their complexions, hair, beauty, and the like; their diet, inclinations and customs, so far as they are not owing to education: the fruitfulness or barrenness of the women; their hard or easy labours: the diseases they are most subject to, and any remarkable symptoms attending them

As to the external productions of the earth, the enquiries are to be these: what grasses, grains and fruit it best produces: the herbs, flowers, and timber trees; and the coppices, groves, forests and woods the country has or wants: what peculiarities are observable in any of them; what soils they most like or dislike, and with what culture they thrive best. Then what animals the country has or wants, both as to wild beasts and birds of prey, and as to poultry and cattle of all sorts; and particularly, if they have any animals that are not common, or any thing particular in those that have. After those, the subterranean stores are to be examined; what minerals the earth affords, and what it wants: then what quarries of stone, and in what manner they lie: what clays and earths are found there; as, clays, marles, fuller's-earths, earths for tobacco-pipes, earth for potter's wares, medicinal earths: what other mineral productions it yields, whether coals, salt mines, or salt springs, alum, vitriol, sulphur, &c. What metals the country yields, with a description of the mines of them; their depths, numbers, situations, signs, waters, damps, quantities of ores, goodness of the ores, and the ways in use for the reducing them to metals.

To these general heads should be added, inquiries into traditions in the country, of any thing relating to it, whether peculiar to it, or only more common there than elsewhere; and where these require learning or skill in the answerer; the utmost care is to be taken to put the people in a way to give their accounts in a satisfactory manner; for a false or bad account of any thing is always much worse than no account at all. Phil. Transf. N° 11.

NATURAL, in music, is applied to a song, the notes whereof move easily and gracefully, giving the performer as little trouble as possible; as when it is not carried too high, or sunk too low, whereby the voice or instrument is in no wise forced or strained. Vid. *Broff.* Mus. Dict. in voc.

NATURAL *harmony*, is that produced by the *natural* and essential chords of the mode. See MODE.

NATURAL *note*, is used in opposition to sharp and flat notes, which are called artificial. See NOTE and SCALE.

The *natural note* ♮, is used to contradict those flats and sharps that are set at the beginning of a staff; and, in such case, you must take the *natural note* as it is in the gamut.

NATURAL *music*, *musica naturale*, among the Italians, is used to signify music formed by the organs of the human voice, unassisted by instruments or other articles.

Natural music is more peculiarly used to denote a song that proceeds in the *natural* order of the notes, without flats or sharps.

NATURALIZATION (*Cycl.*) — By our statutes, foreign protestants are *naturalized* by residing seven years in the British colonies in America. 13 Geo. II. c. 7.

NAVAGIUM, in our old writers, a duty incumbent on tenants to carry their lord's goods in a ship. *Liberi sint, ab omni carriagio*, navagio, &c. *Blount.*

NAVALIA, among the Romans, were docks or ports where ships used to be laid up after building

NAVALIA likewise signified the wharfs or keys at Rome, where the ships used to load and unload their goods, all which were near the Sublician bridge. *Pitisc.* in voc.

NAUCRARI, Ναυκραροι, among the Athenians, a designation given to the chief magistrates of the δημοι, boroughs or townships, which were likewise called ναυκραριαι, because each of them were obliged, besides two horsemen, to furnish out one ship for the public service. *Pott.* Archæol. Græc. l. 1. c. 13. T. 1. p. 78

NAVE (*Cycl.*) — NAVE *of a wheel* is that short thick piece in the center of the wheel, which receives the end of the axle-tree, and in which the ends of the spokes are fixed; it is bound at each end with hoops of iron, called the *nave-bands*: it has likewise in each end of the hole, thro' which the end of the axletree goes, a ring of iron called the *wisher*, which saves the hole of the *nave* from wearing too big.

NAVEL (*Cycl.*) — NAVEL-*string*. It is a method universally received by prudent surgeons and midwives, to make an exact ligature upon the umbilical cord or *navel-string* of the new-born infant, lest it should bleed to death thro' the vessels which compose it. This ligature is to be made, as soon as the infant and after-burthen are delivered, with a strong thread of about an ell long, folded together four times; and having made a knot at one end, it is then to be passed twice round the *navel-string*, at about two or three fingers breadth from the abdomen, and afterwards tied with a double knot: this done, the cord leading to the placenta may be divided with a pair of scissars below the ligature, and the wounded part belonging to the infant dressed with lint, after which it may be left to the nurse till it becomes dry, and falls off of itself.

There have been instances of some children receiving no harm from the cutting the *navel-string*, without the ceremony of the ligature; but as there have also been too many instances of their dying by the omission, and as the operation is so easy, the midwife is unpardonable who omits it. *Heister*'s Surgery, p 22.

Dr. Schulze contradicts the common opinion concerning the umbilical vessels: he endeavours to prove, that the *navel* is not formed by the ligature which the midwives make, or by animals gnawing the *navel-string* of their young with their teeth, but by nature; and that the umbilical vessels separate spontaneously, or with very little force, from the interior surface of the skin; after which, the umbilical vessels within the young creature's body contract and shrivel, their extremity by which they adhered to the *navel* becoming black and pointed, as if they had been burnt, and at last disappear altogether: for, says he, what are commonly described as these vessels changed into ligaments, are no other than the sheaths in which they were formerly contained. From this doctrine he concludes, that it is unnecessary to make any ligature upon the *navel-string* after birth.

In confirmation of this, Dr. Eller relates several instances of the *navel strings* of children being left untied after they were cut, without being attended with any hæmorrhage, or other bad consequence. Commerc. Norimb. 1733. Hebd. 48. §. 2.

Mr. Monro is of opinion, that the fœtus in viviparous animals receives its nutrition from the umbilical vessels alone. See FOETUS.

It has been observed, that in blowing into the placenta by the umbilical vessels, the air and the blood were easily forced out of it, by that surface of the placenta which is affixed to the uterus; but that they could by no means be driven out at the other

other furface which is toward the fœtus. Hence it is to be obferved, that the uterus appears not to be covered by any membrane within, and that the placenta alfo has none on that fide where it adheres to the womb, fo that there is nothing to prevent the blood from readily flowing from the uterus into the placenta, and thence to the child. What we ufually underftand by the word membrane is a covering of fo clofe a texture, as to keep out air, or fluids; and it is very evident to reafon, that the placenta ought to have none fuch on that part where it is to communicate with the uterus; neither can the eye difcover any fuch there, though on the other fide it is eafy to diftinguifh one.

The *navel-ftring*, befide its vein, and its two arteries, is compofed of a fpongy fubftance, in which thefe blood veffels are lodged; this fpongy fubftance is compofed of a number of cellules which communicate with one another, and contain a glutinous liquor, which is ufually found in them in great abundance: if we confider the *navel-ftring* as a cylinder, the blood veffels run in a fpiral round its axis, and are laid one over another, but that differently in different fubjects; hence it is that the *navel-ftring* is tortuous.

When the veffels have run through the whole length of the *navel-ftring* in the fame diameter, they break into a number of branches, and enter the placenta, where they afterwards divide themfelves into capillary ramifications. The diameter of the vein is all the way double to that of both the arteries; fo that it contains twice as much blood as the two arteries together. If the *navel-ftring* were only compofed of thefe three veffels, the fœtus, in moving, might eafily comprefs them in fuch manner, as to ftop the current of the blood, and its inevitable death muft be the confequence of this; but nature having provided this fpongy, or cellular fubftance, for their lodgement, this is able to give way to them, when preffed in any direction, and enables them, therefore, to bear a confiderable force, without the current of the blood being ftopped by them in it; nor is the glutinous liquor, of which thofe cells are full, of little ufe in lubricating thefe veffels. Mem. Acad. Par. 1714.

NAVEL-*wort*, *cotyledon*, in botany, the name of a genus of plants, the characters of which are thefe: the flower is compofed of one leaf, fafhioned into a hell-fhape, with a long tube, and divided into feveral fegments at the end: from the center of the cup there arifes a piftil, which perforates the bottom of the flower, and ripens afterwards into a fruit compofed of feveral fmall fheaths of capfules, collected into a fort of head, and all opening at their tops, and ufually containing an extremely minute feed.

The fpecies of *cotyledon* enumerated by Mr. Tournefort are thefe: 1. The common kind called wall *navel-wort*, and *umbilicus veneris*. 2. The great Portugal kind. 3. The yellow-flowered kind, with a long, tuberofe, and creeping root. 4. The middle-fized *cotyledon*, with a yellow flower. 5. The fhrub, African *cotyledon*, with round leaves, bordered with an edge of purple, ufually called the round-leaved, hoary, African *fedum*, or *houfeleek*. 6. The thick, or cylindric-leaved, African *cotyledon*, with beautiful purple flowers, known alfo to many under the name of a *fedum*, or *houfeleek*. 7. The long-leaved, African *cotyledon*, with fibrofe roots, and umbellated flowers. 8. The fibrofe-rooted, fea *cotyledon*, with houfeleek leaves, and flefh-coloured flowers. Thefe are the genuine fpecies of *cotyledon*, but authors who have lefs accurately examined plants, have ranked under this name feveral which are fpecies of houfeleek, of geum, and of faxifrage. *Tourn.* Inft. p. 90.

The *cotyledons*, when not in flower, may ufually be known by having thick, tuberofe roots, and thick or fatty roundifh leaves. Thefe, however, are found to be no certain characters, as there are plants truly of this genus, which have long leaves, and fibrofe roots.

NAVETTE, the name by which moft of the European nations call the *napus*, or *bunias fylveftris* of Lobel, the plant from the feeds of which the oil which we call rape oil, and the French and others *navette* oil, is expreffed. The plant is cultivated in many parts of England, and in other countries, for the fake of the feed; the oil drawn from this is ufed by many artificers, and is of a fine yellow colour, and the fmell is not offenfive. *Lemery* Dict. of Drugs.

NAVICULA, in natural hiftory, a name given by a late French author to the clafs of fhells called by us the *nautili*. See NAUTILUS.

NAVIGATION (*Cycl.*) — *Sub marine* NAVIGATION, or the art of failing under water, is mentioned by Mr. Boyle as the defideratum of the art of *navigation*. This was attempted, and fuccefsfully, according to him, by Cornelius Drebbel; feveral perfons who were in the boat breathing freely all the time. *Boyle's* Works, abr. Vol. 1. p. 130.

NAVIGATOR, in the fea language, ufually denotes a perfon capable of carrying, or guiding a fhip to any place defired.

NAULIUM, in antiquity, a mufical inftrument otherwife called *nablum*. See NABLUM.

NAULUM, among the Romans, properly fignified freight; whence it is ufed to denote a piece of money put into the mouth of a perfon deceafed, to pay Charon the ferry-man for his paffage: this piece was to be of the current coin of the emperor then reigning; fo that from it the time of the perfon's death may be known. *Danet.* in voc.

NAUPLIUS, in natural hiftory, a name by which fome authors have called the *nautilus*, as well the papyraceous, as the chambered kind. See NAUTILUS.

NAUTICUS (*Cycl.*) — NAUTICUS, in natural hiftory, a name given by fome to the *nautilus*. See NAUTILUS.

NAUTILUS, (*Cycl.*) in natural hiftory, the name of a genus of fhell-fifh, the characters of which are thefe: it expreffes, in general, in every fpecies, the figure of a boat, or veffel, made for fwimming on the water; but in the different fpecies, it is of very different figures, roundifh, or oblong, thin, or thick, furrowed, or fmooth, and fometimes is auriculated, fometimes not. Bonani obferves that this genus of fhell-fifh is very well named from the Greek ναυτίλος, which fignifies both a fifh, and a failor, for that the fhells of all the *nautili* carry the appearance of a boat, or fhip, with a very high poop.

Different authors, among the antients and moderns, have called the *nautilus* by the names of *pompilus*, *nauplius*, *nauticus*, *ovum polypi*, *polypus teftaceus*, and the French call it *le voilier*. It is fuppofed that men firft learned the method of failing in veffels, from what they faw practifed by this creature.

We at prefent know two diftinct genera of *nautilus*, the thin and the thick-fhelled *nautilus*. The firft is called *nautilus papyraceus*, and its fhell feems indeed no thicker, or ftronger, than a piece of paper, when out of the water. This fpecies is not at all faftened to its fhell, but there is an opinion as old as the days of Pliny, that this creature creeps out of its fhell, and goes on fhore to feed. When this fpecies is to fail, it extends two of its arms on high, and between thefe, fupports a membrane, which it throws out on this occafion; this ferves for its fail, and the two other arms it hangs out of the fhell, to ferve occafionally either as oars, or as a fteerage; but this laft office is generally ferved by the tail. When the fea is calm, it is frequent to fee numbers of thefe creatures diverting themfelves with failing about in this manner; but as foon as a ftorm rifes, or any thing gives them difturbance, they draw in their legs, and take in as much water as makes them fomewhat heavier than the fea water in which they fwim, and they then fink to the bottom. The manner of their voiding this abundant water when they would rife again, is by a number of holes, of which their legs are full. Hiftoir. Natur. Eclair. Part. 2. p. 248.

The other *nautilus*, whofe fhell is thick, never quits that habitation. This fhell is divided into forty, or more partitions, which grow fmaller and fmaller as they approach the extremity, or center of the fhell: between every one of thefe cells, and the adjoining ones, there is a communication, by means of a hole in the center of every one of the partitions. Through this hole there runs a pipe, which is of the whole length of the fhell. It is fuppofed by many that the fifh occafionally changes the place of its refidence, by removing from one to another of thefe cells, through this pipe in the little hole; but this is by no means probable, as the body of the fifh muft neceffarily be crufhed to death, if it were poffible to make it pafs through fuch a hole. It feems, therefore, much more probable, that the fifh occupies always the largeft chamber in its fhell, that is, it lives in the cavity between the mouth and the firft partition; and that it never removes out of this, but that all the apparatus of cells, and a pipe of communication which we fo much admire, ferves only to admit occafionally air, or water, into the fhell, in fuch proportion as may ferve the creature in its intentions of finking or fwimming. *Rumphius*, p. 17. fig. b.

Ariftotle has evidently defcribed two fpecies of *nautili*, and fome authors have thought he defcribed three; of this number is Bellonius, whom Rondeletius treats very feverely for the error of this opinion; but it is cuftomary with Rondeletius to be fevere upon Bellonius. *Bonani*, p. 89.

Some authors call this fhell *concha margaritifera*; but this can be only on occafion of the fine colour of its infide, which is more beautiful than any other mother of pearl; for it has not been obferved that this fpecies of fifh ever produced pearls.

It muft be obferved that the polypus is by no means to be confounded with the paper-fhelled *nautilus*, notwithftanding the great refemblance in the arms and body of the enclofed fifh; nor is the cornu ammonis, fo frequently found foffile, to be confounded with the thick-fhelled *nautilus*, though the concamerations, and general ftructure of the fhell is alike in both, for there are great and effential differences between all thefe genera. See the article CORNU *Ammonis*, &c.

The three principal differences of the *nautilus* clafs are, that fome are papyraceous, fome are auriculated, and fome are umbilicated. *Rondelet.* p. 98.

The feveral known fpecies of *nautilus* are thefe: 1. The great, fmooth, and thick *nautilus*. 2. The little *nautilus*, with a fmooth and thick fhell. 3 The fmooth, and thick, umbilicated *nautilus*. 4. The common, concamerated *nautilus*. 5. The furrowed, and empty *nautilus*, with no diaphragms, or feparation within. 6. The thin, and flatted, papyraceous *nautilus*. 7. The auriculated *nautilus*, with a wider fhell. 8. The undulated, and furrowed *nautilus*, with dents on each fide the edge. 9. The *nautilus* with a ridged and ferrated back. This laft fpecies is often found in the cabinets with-

out

out its outer coat, and the shell then looks all over like the most beautiful mother of pearl. Hist. Natur. Eclair Part. 2. p. 249. See Tab. of Fossils, Class 9. and Tab. of Shells, N° 8.

NEALED, at sea, is used when the sounding is deep water close to the shore: it is then said to be *nealed to*; as also when the shore is sandy, clayey, oosy, or foul and rocky.

NEAPOLITAN *disease*, a name given by many authors to the venereal disease; and from hence came the name of the *Neapolitan* ointment, which is a mixture of quicksilver, and other things into an ointment, intended as a cure for it.

NEAR, or *No* NEAR, at sea, a word of command from him that conds the ship, to the man at the helm, requiring him to let her fall to the leeward.

NEBEL, in the Jewish antiquities, a kind of musical instrument See NABLUM.

NEBRITES, in natural history, a name given by the antients to a stone held sacred to Bacchus. It was of the brownish yellow colour of the skin of the young fawn, with some variegations, and was semi-pellucid: it seems to have been the same with some of our agates, with a yellow ground; the antients, however, do not appear to have been very determinate in their accounts of it, for Pliny mentions another kind of it, which was black.

NEBRUS, in natural history, a name given by the antients to the *hinnuleus*, a deer of one year old. In the next year it is called *pattalia*; in the third *dicrota*; and in the fourth *cladii*; the word *ceraste* was used as the name of this animal when of a greater age than this.

NEBULGEN, a word used by some of the chemical writers to express what they call a salt generated by the moisture of the air falling upon stones in the fields, and there indurated by the heat of the sun into the form of a dry salt.

NECESSARIO, in the Italian music. This word is prefixed to certain parts in music, as *a doi violini necessario*, i. e. that must be played by two violins; *canto necessario* is used to signify much the same as *concertante*. See CONCERTANTE.

Every mode has certain chords, which may be called its necessary, or essential chords. Vid. *Bross.* Dict. Mus. in voc.

NECHIASECH, an obscure word coined by Paracelsus, and very frequently used by him, and his followers; he seems to understand by it saline, corrosive, and corroding particles.

NECK (*Cycl.*) — There are several sorts of wounds in the *neck*; sometimes the seat of the wound is only in the common integuments, and muscular flesh; this is attended with very little danger: but the most dangerous, and, indeed, generally incurable wounds, are those of the larger blood vessels in these parts: such are those of the jugular veins, and carotid and vertebral arteries; or where the aspera arteria is wounded, or the gula, the medulla spinalis, the nerves that descend by the *neck*, or when several of these parts are wounded at the same time.

Wounds of the arteries of the *neck* are scarce ever to be remedied. The patient usually bleeds to death, before a surgeon can be had in these cases; but even if the surgeon were present at the instant the wound was inflicted, the largeness of the arteries, their vicinity to the heart, and the impossibility of making a sufficient pressure upon the wounded vessel in this part, give but little hope of relief.

Wounds in the external jugular veins are not of great danger, if a surgeon be applied to in time; but wounds in the internal jugulars are very dangerous, partly from their size, which is of the thickness of one's finger, and, partly from their situation, which is so deep that no proper application can reach them to any advantage. Wounds in this vein are usually esteemed mortal, but it is sometimes possible to save life in this case.

Wounds of the aspera arteria, or windpipe, are usually deemed mortal, where the windpipe is entirely divided, or is wounded in its lower part, within the cavity of the thorax, or joined with a wound of the carotid arteries, or internal jugulars, which is frequently the case: but if the windpipe is only wounded in its fore-part, and the neighbouring vessels remain unhurt, it is usually found curable.

Wounds of the gula, or œsophagus, afford very little hopes of recovery, where it is much wounded, or entirely divided, because, in this case, not only the office of deglutition is cut off; but the part is so situated that it is impossible almost to wound it, without injuring, at the same time, some of the neighbouring nerves, and blood-vessels. But when the gula only is wounded, and the wound small, there is some hope of a recovery.

Wounds in the medulla spinalis, in one part, are very dangerous, but more particularly so when inflicted on that part of it which presses through the neck. It is no wonder, therefore, that scarce any recover after a considerable wound of this kind; which it is impossible should happen without wounding the vertebral veins and arteries at the same time; and the situation of the part is such that it is impossible to convey proper remedies to them. Nor are wounds of the large nerves of the neck less dangerous than these; for, if they are divided, the parts of the thorax and abdomen to which nature has determined them, immediately lose their assistance, and of consequence become unequal to the offices for which they were intended.

For the cure of wounds in the *neck*, the method is as different as the nature of those wounds. Where the integuments, and muscular flesh alone are wounded, the common method of curing slight wounds takes place. Where the external jugular is hurt, the same methods used after bleeding in that vein prove sufficient. When the internal jugular has received a small wound, the hæmorrhage will be easily stopped by filling the wound well with dry lint; or with the puff ball, or dusty mushroom; lodging, over these applications, square bolsters, and securing all with a bandage, drawn as tight as the nature of the part will admit. Where this method does not take place, the surgeon should make a proper pressure on the wounded part with his finger, till the hæmorrhage is entirely stopped. The same methods must be used to the wounds of the vertebral veins; and when the hæmorrhage is once stopped, the dressings applied are not to be removed for three days, and then a vulnerary balsam and plaister applied to heal the wound. In large wounds, or an entire division of the internal jugular, the surgeon, if present in time, should make a firm pressure with his finger on the wounded part, and make incisions, lengthways, above the wound, till he can get at the vessel, and then make a firm ligature upon it, by the assistance of a crooked needle.

In case of a wound of the carotid artery, a surgeon, if present in time, should use the same method as in those of the internal jugular vein. This method is more likely to have success in wounds of the upper and middle part of that vessel, than in those of the lower part of it; and where the wound is not in the trunk of the artery, but in one of its branches near the head, you should fill up the wound with lint dipt in some styptic liquor, and then cover it up with thick compresses, securing all with a tight bandage, and ordering an assistant to make a pressure upon the part with his hand, for some time after: and, in these cases, the dressings are not to be removed till the third or fourth day.

In curing the wounds of the aspera arteria, the surgeon ought to clean the wound, and then endeavour to unite the parts by the help of sticking plaisters; or where the wound is large, by making two stitches with a crooked needle, dressing up the wound afterwards in the usual manner, and enjoining the patient to keep his head in a proper situation, that is, somewhat bending downwards. The wound, thus treated, if it has been made either by puncture, or by the cutting of a sharp instrument, will easily heal; but if it has been made by a bullet, and any part of the aspera arteria is carried away, the suture is to no purpose; wounds of this kind are only to be dressed with the vulnerary balsams. If the aspera arteria is entirely divided, and the lower end of it has shrunk into the cavity of the thorax, so that it cannot be laid hold on, there can be no remedy.

When the œsophagus is wounded, what is taken in at the mouth comes out through the wound, and the patient is usually affected with hiccoughs and vomitings. Where this is entirely divided, there is no remedy; but where it is only perforated or wounded in part, the cure may be attempted by dressing it with the vulnerary balsams, endeavouring to unite it by means of sticking plaisters, and enjoining the patient a strict abstinence for some days, and giving nourishing glysters of broth, milk, &c. If nourishment must be taken at length by the mouth, the wound must be perfectly cleaned every time afterwards, and be dressed daily till it heals. Wounds of the medulla spinalis are best dressed with balsam of Peru, or medicines of a like nature, mixed with a small quantity of honey of roses, and spread upon pledgits, and applied moderately warm. Slight wounds of this kind are sometimes healed by this means; but large ones in this part always bring on certain death. *Heister* Surg. p. 74.

In the Memoires de l' Acad. royale des Sciences, Ann. 1730. we have some curious observations by Mr. Winslow on the motions of the *neck*, as also on those of the head and spine.

NECK, in the manege. See CARRYING.

NECK *of the cascabel*, in artillery, is that part betwixt the breech mouldings, and the *cascabel*.

NECK *of a gun* is that part betwixt the muzzle mouldings, and the Cornish ring.

NECOPHORON, in botany, a name used by Pliny, and other authors for the *smilax aspera*, or *rough bindweed*. *Ger.* Emac. Ind. 2.

NECROLIUM, a word used by some of the alchemical writers to express a remedy almost always capable of averting death, and continuing life to its utmost period.

NECROSIS is used by many of the medical writers for a mortification.

NECTAR (*Cycl*) is used by some of the antients to express honey. This signification of the word was owing to the supposition that honey was the drink of the bees; as they esteemed the yellow matter collected on their thighs to be their food. They called the latter ambrosia. It seems that the antients have been more in the right as to their opinion of the ambrosia than other authors, who have usually esteemed that yellow substance to be true wax. But it appears from experiments that it is not really so; nor can wax be separated from it by any of the known processes of chemistry. It seems rather that the bees eat it, agreeably to the opinion of the antients, and that after having served them as nourishmment, it is converted

in

in their bowels into the ſubſtance we call wax. *Reaumur*'s Hiſt. Inſ Vol. 10. p. 50. See Honey.

NECTARINE, a fruit greatly eſteemed for its delicious flavour, and ſuppoſed to have its name from the nectar of the Gods, in heathen ſtories.

It differs in nothing from the peach, but in having a ſmoother ſkin, and a firmer pulp. See Peach.

We have ten kinds of *nectarine* cultivated by the curious in gardening.

1. *Fairchild's early nectarine*; this is a ſmall fruit of a red colour, and very well taſted, and ripens in July, the earlieſt of all this kind

2. The *Elruge nectarine*; this is a larger fruit, of a purple colour on that ſide which was toward the ſun, and of a greeniſh yellow on the other parts This is a very well flavoured *nectarine*, of a ſoft, melting juice, and parts from the ſtone: it ripens toward the end of July.

3. The *Newington nectarine*; this is a fair large fruit, of a fine red toward the ſun, and of a yellowiſh green toward the wall. It has a very rich juice, but the pulp adheres to the ſtone: this ripens in Auguſt.

4. The *ſcarlet nectarine*; this is of a fine glowing red toward the ſun, and of a pale red toward the wall; it ripens in the end of July.

5. The *Brugnon*, or *Italian nectarine*; this is a fair, large fruit, of a deep red next the ſun, but of a ſoft yellow next the wall. The pulp is firm, and of a rich flavour, but cloſely adheres to the ſtone, and is red in that part: this ripens in the middle of Auguſt.

6. The *Roman red nectarine*; this is a very fair large fruit, of a deep purple toward the ſun, and of a greeniſh yellow next the wall. The pulp is very firm and well taſted, but it is red about the ſtone, and adheres firmly to it: this is ripe in the middle of Auguſt.

7. The *Murry nectarine*; this is a middle-ſized fruit, of a dirty red next the ſun, and of a greeniſh yellow next the wall. The pulp is tolerably well flavoured: this ripens in the middle of Auguſt.

8. The *golden nectarine*; this is a fair handſome fruit, of a ſoft red next the ſun, but of a gold yellow next the wall, and its pulp is very yellow, but of a faint red about the ſtone to which it adheres: it is a very well-flavoured kind, and ripens at the end of September.

9. *Temple's nectarine*; this is a very fine kind: it is of a ſoft red toward the ſun, and of a yellowiſh green next the wall. It parts from the ſtone, and is of a very rich flavour; the pulp is white in other parts, but yellowiſh about the ſtone: this ripens in the middle of September.

10. The *Peterborough nectarine*, called by ſome the late, green *nectarine*; this is a middle-ſized fruit, of a pale green colour toward the ſun, and of a whitiſh green toward the wall; the pulp is firm, and well-flavoured: it ripens toward the end of September.

The pruning, planting, and whole culture of this plant is the ſame with that of the peach. *Miller*'s Gard. Dict. See the article Peach.

NECTARIUM, among botaniſts, expreſſes what is only a part of the corolla, ſometimes, though more rarely the whole. It is a part deſtined for the reception of the honey juice of the plant; and is very various in its figure. Sometimes, it is only a hollow in a petal; ſometimes, it is a little ſquamma; ſometimes a tubercle; and ſometimes a plain tube.

NECUIA, in botany, a name given by the antient Greeks to a ſpecies of *mullein*. See Mullein.

The Greeks and Romans both uſed the ſtalks of a peculiar kind of *mullein*, called *thryallis* by Nicander. For the making the wicks of lamps, we have a kind of *mullein* called *lychnites*, and candle-wick *mullein*, from the λυχνῖτις of Dioſcorides; but it is not certain that ours is the ſame plant.

The antients uſed the ſtalks of many different plants for the wicks of their candles, and lamps. The ruſh ſtripped of its bark was as commonly in uſe with them, as with us, for this purpoſe; and they alſo uſed the nettle, this *mullein*, and many other plants, whoſe ſtalks were compoſed of tough filaments, for the ſame purpoſe; beating them out like hemp, and when dry, dipping them in melted reſin, and other ſuch inflammable ſubſtances. When thus prepared, they were readily inflammable, like our flambeaux, and this *mullein* having ſtalks more long, and large, and more firm than all the others, was uſed to make thoſe lights with which they ſet fire to the funeral pile for conſuming the aſhes of their dead friends.

NEEDLE (*Cycl.*) — Needle, in ſurgery. It is to be obſerved, that *needles* of ſilver pierce more eaſily in ſtitching arteries after an amputation, than thoſe made of ſteel. *Monro*, in Med. Eſſ. Edinb. Vol. 5. Art. 41.

NEGATIVE (*Cycl.*) — Negative *power*, in algebra, is uſed for thoſe powers of a quantity which have a negative ſign. Thus a^{-m} is called a negative power. *Negative* powers ariſe from the diviſion of any power of a quantity, by a greater power of the ſame quantity. Thus, $\frac{a^4}{a^6} = a^{4-6} = a^{-2}$; and in general, $\frac{a^m}{a^{m+n}} = a^{-n} = \frac{1}{a^n}$ for $\frac{a^m}{a^{m+n}} = \frac{1}{a^n}$. See Power, *Cycl.*

Negative *ſign* The uſe of the *negative ſign*, in algebra, is attended with ſeveral conſequences that at firſt ſight are admitted with difficulty, and has ſometimes given occaſion to notions that ſeem to have no real foundation. This ſign implies that the real value of the quantity repreſented by the letter to which it is prefixed, is to be ſubtracted; and it ſerves with the poſitive ſign, to keep in view what elements or parts enter into the compoſition of quantities, and in what manner, whether as increments, or decrements, (that is, whether by addition or ſubſtraction) which is of the greateſt uſe in this art.

In conſequence of this, it ſerves to expreſs a quantity of an oppoſite quality to the poſitive, as a line in a contrary poſition; a motion with an oppoſite direction; or a centrifugal force in oppoſition to gravity; and thus often ſaves the trouble of diſtinguiſhing, and demonſtrating ſeparately, the various caſes of proportions, and preſerves their analogy in view. But as the proportions of lines depends on their magnitude only, without regard to their poſition; and motions, and forces, are ſaid to be equal, or unequal, in any given ratio, without regard to their directions; and, in general, the proportion of quantities relates to their magnitude only, without determining whether they are to be conſidered as increments or decrements; ſo there is no ground to imagine any other proportion of $-b$ and $+a$, (or of -1 and 1) than that of the real magnitudes of the quantities repreſented by b and a, whether theſe quantities are, in any particular caſe, to be added, or ſubſtracted. It is the ſame thing to ſubſtract a decrement as to add an equal increment, or to ſubſtract $-b$ from $a-b$, as to add $+b$ to it: and becauſe multiplying a quantity by a *negative* number implies only a repeated ſubſtraction of it, the multiplying $-b$ by $-n$, is ſubſtracting $-b$ as often as there are units in n; and is therefore equivalent to adding $+b$ ſo many times, or the ſame as adding $+nb$. But if we infer from this, that 1 is to $-n$ as $-b$ to nb, according to the rule, that unit is to one of the factors as the other factor is to the product, there is no ground to imagine that there is any myſtery in this, or any other meaning than that the real magnitudes repreſented by 1, n, b, and nb are proportional. For that rule relates only to the magnitude of the factors and product, without determining whether any factor, or the product, is to be added, or ſubtracted. But this likewiſe muſt be determined in algebraic computations; and this is the proper uſe of the rules concerning the ſigns, without which the operation could not proceed. Becauſe a quantity to be ſubſtracted is never produced in compoſition, by any repeated addition of a poſitive, or repeated ſubſtraction of a *negative*, a *negative* ſquare number is never produced by compoſition from the root. Hence $\sqrt{-1}$, or the ſquare root of a *negative*, implies an imaginary quantity; and, in reſolution, is a mark or character of the impoſſible caſes of a problem, unleſs it is compenſated by another imaginary ſymbol, or ſuppoſition, when the whole expreſſion may have a real ſignification. Thus $1+\sqrt{-1}$, and $1-\sqrt{-1}$ taken ſeparately, are imaginary, but their ſum is 2; as the conditions that ſeparately would render the ſolution of a problem impoſſible, in ſome caſes deſtroy each other's effect, when conjoined. In the purſuit of general concluſions, and of ſimple forms for repreſenting them, expreſſions of this kind muſt ſometimes ariſe where the imaginary ſymbol is compenſated in a manner that is not always ſo obvious.

By proper ſubſtitutions, however, the expreſſion may be transformed into another, wherein each particular term may have a real ſignification, as well as the whole expreſſion. The theorems that are ſometimes briefly diſcovered by the uſe of this ſymbol, may be demonſtrated without it, by the inverſe operation, or ſome other way; and though ſuch ſymbols are of ſome uſe in the computations by the method of fluxions, its evidence cannot be ſaid to depend upon arts of this kind. See *MacLaurin*'s Fluxions, B. 2. ch. 1.

NEGRO (*Cycl.*) — Mr. Boyle has obſerved, that the heat of climates cannot be the true cauſe of the colour of *negroes* For though the heat of the ſun may darken the colour of the ſkin, yet experience does not ſhew that heat is ſufficient to produce a true blackneſs, like that of *negroes*. In Africa itſelf many nations of Æthiopia are not *negroes*, nor were there any blacks originally in the Weſt Indies. In many parts of Aſia, under the ſame parallel with the African regions, inhabited by blacks, the people are but tawny. He adds, that there are *negroes* in Africa, beyond the ſouthern tropic, and that a river ſometimes parts nations, one of which is black, and the other but tawny. *Boyle*'s Works abr. Vol. 2. p. 42, 44.

Dr. Barrere alledges that the gall of *negroes* is black, and being mixed with their blood, is depoſited between their ſkin, and ſcarf ſkin. Diſſ. on the phyſ. cauſe of the colour of *negroes*.

We have a diſſertation on this head by Dr. John Mitchell of Virginia, in the Philoſophical Tranſactions, N° 476. Sect. 4. where he advances theſe propoſitions, and enters into a learned detail to ſupport them.

1°. The colour of white people proceeds from the colour which the epidermis tranſmits; that is, from the colour of the parts under the epidermis, rather than from any colour of its own.

2°. The ſkins of *negroes* are of a thicker ſubſtance, and denſer texture, than theſe of white people, and tranſmit no colour through them.

3°. The part of the ſkin which appears black in *negroes*, is the *corpus reticulare cutis*, and external lamella of the epidermis: all other parts are of the ſame colour in them with thoſe of other people, except the fibres which paſs between thoſe two parts.

4°. The colour of *negroes* does not proceed from any black humour, or fluid parts contained in their ſkins; there being none ſuch in any part of their bodies, more than in white people.

5°. The epidermis, eſpecially its external lamella, is divided into two parts by its pores and ſcales, two hundred times leſs than the particles of bodies on which their colours depend.

This is founded on Leuwenhoek's obſervation that a portion of the epidermis no bigger than what can be diſcerned by the naked eye, is divided into 125000 pores, and theſe pores muſt divide ſuch a portion of the ſkin into as many particles. But the particles of bodies on which their colours depend, are, by Sir Iſaac Newton's Optics, Lib. 2. P 3. Prop. 7. 600 times leſs than theſe which can be diſcerned by the naked eye. Therefore the particles of the ſkin muſt be about 200 times leſs than theſe; ſince $\frac{125000}{600} = 208\frac{1}{3}$. It may alſo be obſerved that ſuch a ſmall portion of the epidermis is diviſible into 250 ſcales, which muſt encreaſe the number of its parts.

6°. From theſe propoſitions, and from Sir Iſaac Newton's theory of light and colours, the doctor thinks he may conclude, that the proximate cauſe of the colour of *negroes* is threefold; *viz.* The opacity of their ſkin, proceeding from the thickneſs and denſity of its texture, which obſtructs the tranſmiſſion of the rays of light, from the white and red parts under the ſkin, together with its greater refractive power, which abſorbs theſe rays; and the ſmallneſs of the particles of this ſkin, which hinders it from reflecting any light.

7°. The influence of the ſun, in hot countries, and the manner of life of their inhabitants, are the remote cauſes of the colour of *negroes*, Indians, &c. And the ways of living in uſe amongſt moſt nations of white people, make their colours whiter than they were originally, or would be naturally.

In ſupport of this propoſition, the doctor obſerves, that the ſkin is deprived of its white colour, by the force and influence of the ſun, four ways. 1ſt. By being rendered opaque, from a diſſipation of its more aqueous, and pellucid juices. 2dly. By a concretion of its veſſels and glandules, from this diſſipation of their aqueous contents; which renders the ſkin both thicker and denſer, or more callous and rigid. 3dly. By a new accretion of many new membranes, which render it thick and opaque. 4thly. By encreaſing thoſe parts or principles, in the compoſition of the epidermis, which have the greateſt refractive power; as the terreſtrial and fixed ſaline; but eſpecially the tenaceous ſulphureous, which refract and abſorb light more ſtrongly than any other ſubſtances; while the more tranſparent and pellucid principles, as the aqueous, ſpirituous, and volatile ſaline, are evaporated by the heat, which cauſes the other more fixed principles to be accumulated; and theſe particles being likewiſe more comminuted by the ſun, will, on this account, be black; as happens to oil when well boiled. Theſe cauſes, with thoſe firſt-mentioned, may, the doctor thinks, by conſpiring make the ſkin quite black; eſpecially if we add another effect of the ſun's power, a peculiar necroſis of the epidermis, occaſioned by the f rcible vibrations, contractions, and exſiccations of its fibres by the ſun beams which cauſe it to turn black, as theſe, or other parts do, by the heat of an inflammation, or a fever, in gangrenes, black tongues, &c.

We cannot pretend to follow the author in all the detail of his obſervations on this ſubject, nor of his anſwer to a material objection already mentioned from Mr. Boyle, that the ſun cannot be the cauſe of the colour of *negroes*, becauſe ſeveral nations, in the ſame latitude with thoſe *negroes*, are not made black by it He ſeems to think the heat of Africa greater than that of other parts of the world. Whether it be ſo, or not, is we doubt, not eaſy to determine; but it would be a ſtrong confirmation of his doctrine, if we could ſee any people, originally white, become black and woolly by tranſplantation, or vice verſa.

NEGRO, in zoology, the name of a large bird approaching to the crane kind, and more uſually known among authors by its Braſilian name *jabiru*. See JABIRU.

NELANJENUM, in natural hiſtory, the name of a curious and peculiar foſſile ſubſtance found in the Eaſt-Indies.

It has much the appearance of ſome of our ſteel-grained lead ores, and is very ponderous, but it does not contain any lead; in this it approaches to the nature of that ſubſtance common in Europe, and called blende, or mock lead; but this laſt is foliated, and reſembles the plated lead ores, whereas this reſembles the cloſe ground ores. It is found in the beds of rivers in many places; they calcine it, and, reducing it to powder, mix it with the juice of herbs, and uſe it in ulcers.

NELLA *corvindum*, in natural hiſtory, a name given by the people of the Eaſt-Indies to a very hard ſtone which they uſe as we do emery.

It is of a talcky nature, being compoſed of flaky ſpangles, and a coarſer matter intermixed. They dig it at the foot of ſome mountains, and in ſome other places. It lies ſo near the ſurface that the rice-fields abound with it; and it is ſeen on ſtirring the ground. It is always found in nodules, or detached maſſes, and is uſually of a ſort of iron colour, though ſubject to ſome variations. It is uſed by the common people to ſcower arms, and other iron works; and by the lapidaries, among them, to poliſh rubies, and other ſtones. For this laſt purpoſe they grind it with ſtick lack, and make it into a ſort of cement, with which they daub over the face of the poliſhing machine.

NELLON, in botany, a name given by ſome to rice. It is an Indian word, and properly ſignifies the grain of rice taken off from the ſtalks, but covered with its proper pellicle. The firſt operation to be performed upon this, is the beating it with large ſtones, or other more manageable tools, till this ſkin flies off. Then it is to be dried in the ſun, and, after that beat a ſecond time, to get off its thin, internal, rediſh coat: when this is done, it is in a ſtate to be uſed, and it is then only that the Indians call it *ariſi*, the word from which we formed our word rice. Obſervations ſur les Coutumes de l' Aſie.

NELUMBO, in botany, the name of a genus of plants, uſually confounded with the nymphæa.

The characters of the *nelumbo* are theſe: The flower is like that of the nymphæa, but the fruit wholly different, not only in ſhape, but in ſtructure, being not divided into ſeveral cells, but having the ſeeds placed irregularly, at diſtances from one another in it

There is only one known ſpecies of this genus, which is the *nelumbo* of the Ceylonefe, called by others the *Indian nymphæa*, and *faba Ægyptiaca*, the *Ægyptian bean*. *Tourn.* Inſt. p. 261.

NENUPHAR. The antient writers on the materia medica, have all mentioned a peculiar ſpecies of this plant, under the name of *nenuphar indicum*. The roots of this they call *fel*, and Aviſenna ſays, that they have the ſame virtues with the mandrake. *Fel* is alſo the name of another very different medicine uſed in thoſe times; a fruit of a climbing plant, of the ſize and figure of a cucumber, as to ſtalks and leaves, but bearing for fruit this *fel*, which was a ſort of nut of the ſize of a piſtachea nut, and covered with a thick ſhell.

This *fel* was of the nature of the *bel* and *ſel*, two other fruits of a like ſort, all heating and drying. Theſe were qualities altogether oppoſite to thoſe of the mandrake; and the ſynonymous uſe of the word *fel* for theſe two things not having been obſerved, the author is accuſed of contradicting himſelf in different parts of his works, when, in reality, he is treating of contrary things, tho' unluckily called by the ſame name; the one a cold root, the other a hot fruit.

NENUPHAR, in botany, is alſo a name uſed by ſome authors for the *water-lilly*. *Ger.* Emac. Ind. 2.

NENUFARINI, a name given by the adepts to a kind of imaginary ſpirits which they ſuppoſe to inhabit the air, and to direct and govern many things on earth.

NEOCORI, Νεωκοροι, among the antients, perſons whoſe buſineſs it was to take care of temples, and other conſecrated places. They were otherwiſe called *æditui*. *Pitiſc.* in voc. See the article ÆDITUUS.

NEOENIA, Νεοινια, in antiquity, a feſtival celebrated in honour of Bacchus, when the new wine was firſt taſted. *Pott.* Archæol. T. 1. p. 416.

NEOMENIA, Νεομηνια, in antiquity. See NUMENIA.

NEOPTOLEMIA, Νεοπτολεμεια, in antiquity, a feſtival celebrated by the Delphians with much pomp and ſplendor, in memory of Neoptolemus, the ſon of Achilles, who was ſlain in an attempt to ſack Apollo's temple, which he undertook in revenge of his father's death, to which that god was acceſſary. *Pot.* Archæol. Græc. T. 1. p. 416.

NEOTTIA, in botany, the name given by Linnæus to the plant called by Tournefort and others *nidus avis*, and by Ruppius *corallorhiza*. *Linnæi* Gen. Pl. p. 434. See NIDUS *avis*.

NEPA, a word uſed by naturaliſts ſometimes to expreſs a *crab*, ſometimes for a *ſcorpion*, and ſometimes for a plant, called by the botaniſts *geniſta Spartium*.

NEPENTHES, in botany, the name of a genus of plants, the characters of which are theſe: the perianthium is divided into four roundiſh ſegments; there are no petals, and ſcarce any ſtamina; but four antheræ are affixed to the ſtylus near its top; the piſtil has an extremely ſlender germen; the ſtyle is pointed, and of the length of the cup; and the ſtigma is obtuſe; the fruit is an oblong, columnar, truncated capſule, faintly quadrangular, conſiſting of four cells, and ma e up of four valves. The ſeeds are numerous, pointed, and of a chaffy ſtructure, and are ſhorter than the capſule. *Linnæi* Gen. Pl. p. 437.

NEPETA, *catmint*, in medicine. See CATMINT.

NEPHALIA, among the Greeks, a feſtival called the feaſt of ſober men, at which the Athenians offered to the ſun and moon, to Aurora and Venus, a drink made of water and honey. They burnt all ſorts of wood on the occaſion, except the vine and fig-tree. *Danet* in voc.

NEPHRITICUM *lignum*, or NEPHRITIC *wood*. See TRANSMUTATION *of colours*.

NEPHRITIS, *(Cycl.)* in medicine, is uſed for an inflammatory affection of the kidneys, owing its origin to a ſtagnatory congeſtion of blood in them, which nature ſeems to have intended to direct to the internal, hæmorrhoidal veſſels, thence to be diſcharged to eaſe her of the load of a plethora.

The ſimple *nephritis* is thus carefully to be diſtinguiſhed from the

the calculofe one; for the former may, for a long time, affect a patient without any thing of a ftone being in the cafe; and, on the contrary, a ftone may be long lodged in the kidneys, without its bringing on any fuch complaint as the *nephritis*.

In the fimple *nephritis* there is always a fenfation of pain and heat about the loins, which is plainly perceived to lie deep within the flefh, but is never very acute. On the contrary, in the calculofe *nephritis*, the pain is violently fharp.

In the fimple *nephritis*, the urine, after it has ftood fome time, fhoots to the fides of the pot pellucid cryftals of a redifh colour. But, in the calculofe, the heavy matter immediately precipitates itfelf to the bottom, and is fabulous and gritty; and the fimple *nephritis* is always greatly relieved by a gentle motion of the body, as walking, or the like; whereas all motion of the body exafperates the calculofe *nephritis*.

The *nephritis* is diftinguifhed alfo from the ifchiatic pains, which fometimes run up to the fame parts, by its being evidently perceived to lie deep within the flefh, whereas thofe pains affect the external mufcles; yet there is fuch a connection and confent of parts in thefe cafes, that not unfrequently the one is taken for the other.

Signs of it. Thefe are a pain in the region of the loins, which does not ufually affect both, but only, or, at leaft, principally, one fide, ufually the left. The pain is at firft tenfive and dull, but afterwards becomes more acute; in the beginning it is often attended with a chillnefs, and general trembling, which is fucceeded by a heat, and acrid gnawing, fcarce to be fupported; and this is ufually attended with a want of appetite, and lofs of ftrength, and a continual, though not violent, thirft. The fleep is unfound, and there ufually is either a dull pain in the head, or a vertiginous complaint, more or lefs violent; and very frequently naufeas, and reachings to vomit, attend the fits, or prognofticate the accefs of them.

The pain never extends itfelf down the whole thigh, nor is that ever wholly numb'd, or rendered torpid by it; and the diforder does not feem continual, but attacks the patient at different times, and thefe after confiderably long intervals, if he live regularly. The bowels are ufually coftive at the time of the fits, and there is a frequent want of making water, though very little is voided at a time, and that thin, when the pain is violent; when it is more obtufe, the urine is commonly thick, and has, as it were, threads in it, of a fort of mucilaginous matter; and to this it is to be added, that fometimes the fpermatic veffels which run to the teftes become hard and tumid.

Men are more fubject to this difeafe than women, and of thofe, fuch principally as are plethoric; and people in the middle and later periods of life, are, in general, more fubject to it than thofe who are younger. In general, young people are not fubject to this difeafe, unlefs it be from an hereditary difpofition, or fome very powerful, and violent, external caufes. Men are much oftener tormented with the *nephritis* than women, and none fo often fall into it as thofe who have omitted the ufual evacuations, and afterwards fall into violent exercifes; and finally, people who have the gout and the fciatica, are ufually alfo *nephritic*.

Caufes of it. Thefe are principally the fuppreffion of natural evacuations; or the omiffion of habitual artificial ones; the abufe of hot medicines of the diuretic kind, fuch as the oils of turpentine, and juniper, and the balfam of fulphur; as alfo the over frequent ufe of venery, and the taking medicines to provoke to it; violent paffions, or great and fatiguing exercifes; external injuries by blows, falls, or the like; and the ufe of a too hot diet, and too much of ftrong liquors.

Prognoftics. The fimple *nephritis* may ufually be cured, if properly treated, but the calculous one fcarce ever can; and tho' all inflammations of the internal parts are juftly accounted very dangerous, yet this is the leaft fo of all others, becaufe the urine continually paffing through the part, abfterges and cleanfes it, and prevents corruption, or gatherings of matter. The greateft danger is in fuch as have a difpofition to generate calculous matter, and to hectics. In thefe cafes the difeafe is apt foon to change from its fimple nature.

It is very rare that both kidneys are feized with this diftemper, but ufually the left alone fuffers by it: the more inflammatory the ftate of the body is, the worfe it is with perfons afflicted with this difeafe, and the more they are fubject to it: thus young people who have often a turgefcence of blood, are more frequently fubject to this difeafe than old perfons, and are with more difficulty cured of it: and it is an obfervation as old as Hippocrates, that the coming on of hæmorrhages from the internal hæmorrhoids cures this difeafe.

Method of cure. In the time of the fit, the firft thing to be done is the opening the belly by a clyfter of the emollient kind, prepared of milk or broth. Simon Pauli exprefly directs, from repeated experience of its good effects, a decoction of the herb veronica, or fpeedwell, with fome oil, and a little falt. After this, powders of nitre, cinnabar, and tartarum vitriolatum, fhould be taken every three hours; and, towards the evening, there fhould be mixed with one of thefe dofes, eight grains of diaphoretic antimony, and four of crab's eyes. Emulfions of the cold feeds in the cooling fimple waters, are alfo of great ufe; and to the common feeds ufed on this occafion, may be added thofe of poppies, and of carduus mariæ. In the mean time external applications may alfo be ufed with fome fuccefs; fuch as bags of chamomile, melilot, and fenugreek feed dry, and heated at the fire; as alfo the fpirits of ferpyllum, and the like, and the foap plaifter: to all thefe may be added the ufe of leeches, which are, indeed, a great relief in all the diftemperatures of the urinary parts; and, finally, during the whole courfe of the cure, refrigerating and diluting liquors are to be drank in large quantities, as barley water, tea, and the like.

After the fit, the neceffary treatment to prevent a return, is to bleed regularly, fpring and autumn; to take, at times, gentle purges of rhubarb, fena, and the like; to keep the hæmorrhoidal difcharges in their proper ftate; and the habitual coftivenefs which ufually attends people in this difeafe is to be taken off by a moift and lubricating diet; and wine, and ftrong liquors, are to be avoided. *Junker's* Confp. Med. p 216, feq.

NEPHROMETRÆ, a name given by fome authors to the mufcles of the loins, called by the generality of medical authors *pfoæ*.

NEPHROTOMY, in furgery, the cutting into the kidneys, in cafe of the ftone being lodged there, and taking it out in the fame way as from the bladder.

This is an operation which has been very little practifed, and ufually fuppofed to be attended with very great danger: few authors who have treated of thefe difeafes have fo much as mentioned this operation, and the few that have named it, have generally condemned it. Sinibaldus fancying that it was an operation antiently practifed, ftrove very earneftly, indeed, to have it revived. He has called in the opinion of Hippocrates to fupport his account of its having been done with fafety, and advifes the furgeons to try their hand on brutes firft, and accuftom themfelves to the operation, and then not to fear it in regard to men.

It is certain that a ftone in the kidney is fo terrible a difeafe, that it is very much to be wifhed that fome fafe operation could be invented to cure it; but it is making too free with Hippocrates, to fay that he countenances or directs fuch an operation in general. His words feem to exprefs only the making an incifion near the kidney; but even if they are to be underftood as directing the cutting into it, it is under fuch reftrictions, that opportunities will very feldom offer; and, when they do, a common furgeon would not fcruple performing all that is directed, without either confulting Hippocrates, or trying his fkill upon brutes. Hippocrates only advifes it in cafe of a fwelling and impofthumation, where there is matter formed, and the tumor manifefts itfelf upon the furface. In this cafe every furgeon would know it was his bufinefs to make an incifion. Phil. Tranf. N° 223. p. 334.

Cafes requiring this are frequent, and that even without a ftone. An inflammation in a kidney degenerates into an abfcefs, and when matter is formed, the furgeon opens the tumor, and the matter is difcharged. Sometimes ftones bred in the kidneys caufe impofthumations; the furgeon opens thefe, and the ftones are brought away together with the matter. Nay, nature herfelf has done the whole for fome people, and the ftones have made their way through the kidney, and through the integuments, &c.

Tulpius gives an account, from his own obfervation, of a man who had a ftone in his kidney, which, after many years, difcharged itfelf through the loins, and occafioned a fiftula in the part, through which the urine was long voided, together with the matter. The attempts of many furgeons to heal this fiftula proved vain, and, at length, one fucceeding fo far as to ftop up the mouth of the ulcer, the matter which ufed to be difcharged from it was thrown into the abdomen, and the man died of a fever. Tulpius gives the death of this perfon as an objection againft the operation of *nephrotomy* in general, as he fuppofes a fimilar fate might attend the wounds made in thefe parts by the furgeon.

From an impartial examination of the works of Hippocrates, it does not appear that the cutting for the ftone in the kidneys was regularly practifed in his time, nor, indeed, for many ages after; for Celfus makes no mention of it, although he is very particular upon the operation of cutting for the ftone in the bladder. Galen is fo copious a writer, that he never miffes any thing practifed either in his own time, or before it, in his accounts of difeafes, yet he mentions nothing of this operation, though he is very long upon the article of the difeafes of the kidneys. Cardan, indeed, mentions this operation as one of thofe of the antients which were practifed in his time. His hafty reading the words of Hippocrates has led him into this error, and he lays the fault of its being now loft, in a great meafure, on Galen's omitting to mention it. It is wrong to accufe Galen of this omiffion, fince neither Celfus, nor Ruffus, who preceded him, nor Aretæus who was his cotemporary, nor, indeed, any of the Greek or Latin phyficians, have named it, though they, as well as the moderns, mention occafionally an abfcefs in the kidneys, and the manner of curing it.

The Arabians, indeed, mention the operation as practifed and countenanced by fome perfons before their time; but they all join in condemning it as a bold and hazardous operation, from which very little good is to be expected, and which fets the life of the patient in the moft imminent danger. Avifenna fpeaks of it as the act of a madman, and, it feems, that it was fometimes

ſometimes practiſed in his time, but by his manner of naming it, ſeems to have been only done by ſome mountebanks, who having no reputation to loſe, ventured boldly, and ſometimes had ſucceſs. The reſt of the Arabians are ſilent about the operation, and it ſeems to have been only practiſed by a few people in the days of this author, and wholly diſcountenanced afterwards, from its bad ſucceſs.

Among the moderns, the firſt who has named it is Rouſſet, in his treatiſe on the Cæſarian ſection. In order to invite men to countenance the Cæſarian operation, he recommends ſeveral other deſperate ones, and among the reſt, this of *nephrotomy*: but he is not able to produce one inſtance of its having been practiſed either in his own, or earlier times, but when there was an abſceſs and an external tumor. Cælius Rodeginus gives indeed a very remarkable inſtance of an operation of this kind being performed by chance, by a woman who, in the agony of her pain from the ſtone in the kidney, ſcratched with her own nails, till ſhe tore thro' the fleſh ſo deep, that eighteen ſtones were diſcharged at the wound.

The general opinion of authors is thus againſt the operation; and the moſt famed among thoſe who have treated of wounds of the kidneys ſay, that any wound which enters into the pelvis is mortal. Yet this opinion, tho' general, is not certain or determinate; and we have an account in the Philoſophical tranſactions of the operation of *nephrotomy* being performed with ſucceſs, by Marchetti of Padua, on Mr. Hobſon the Engliſh conſul at Venice. Phil. Tranſ. N° 223. p. 337.

NEPTA, a name uſed by ſome authors for the *aſphaltum*. It ſeems a corruption of *naphtha*.

NEPTUNE's *cap*, a name given by naturaliſts to a remarkable ſpecies of marine fungus, which is never found affixed to any ſolid body, but always looſe, and rolling about at the bottom of the ſea. Its uſual ſize is about five inches in height, and ſix or ſeven in diameter at the baſe. It gradually becomes narrower from the baſe to the ſummit, where it terminates in a round end, ornamented with cluſters of a foliaceous ſort of ſubſtances, reſembling a cock's comb, but of the ſame matter with the reſt of the plant.

Its internal ſurface is very different from this: it is lightly furrowed down the ſides, and beſet with a number of ſmall protuberances, with obtuſe points. Some of theſe, when ſmall, are found with a pedicle growing to them. This is always of a very brittle ſubſtance, and it is probable that all thoſe found looſe had originally ſuch pedicles, by which they adhered to ſome ſolid body, in the manner of the corals, and other ſea plants; but that its extreme brittleneſs occaſions it to be ſoon broken off, by the motion of the water, after which the plant rolls looſe about, and takes in its nouriſhment at its ſeveral pores, by means of the water which every way ſurrounds it. It is not probable that theſe and the like ſea plants are nouriſhed only by ſea water; but that there is in the ſea a ſort of mud continually formed out of the decayed particles of animals, and the foſter vegetables, which may be ſuppoſed much to reſemble the common vegetable mold in its uſes, as it has much the ſame origin; and this, or at leaſt its finer and lighter parts, may be conveyed by water into the pores of theſe plants, and nouriſh them. Mem. Acad. Par. 1700.

NERANTZIUM, in botany, a name given by ſome of the Greek writers to the citron tree. The antient Greeks were not acquainted with the word, and it ſeems to have been formed in the barbarous ages from the word *narange*, the name by which the Arabian phyſicians called the ſame fruit.

NERFLING, in zoology, the name of a freſh water fiſh of the leather-mouth'd kind, common in ſome of the lakes in Germany, and there called alſo the *erff* or *oorve*, and ſeeming to be the ſame with the common Engliſh rudd. See RUBELLIO. There are two kinds of this fiſh, the fleſh of the one of which, when dreſſed, is white, and that of the other yellowiſh or rediſh. The latter kind is moſt valued. *Willughby*'s Hiſt. Piſc. p. 252. *Geſner* de Piſc.

NERION, *oleander*, in botany, the name of a genus of plants, the characters of which are theſe: the flower is compoſed of only one leaf, and is of the funnel-faſhion'd kind, and divided into many ſegments at the edge. The piſtil ariſes from the cup, and is fixed in the manner of a nail to the hinder part of the flower: this finally becomes a fruit of a cylindric ſhape, compoſed of two pods, which contain ſeeds winged with down. See Tab. I. of Botany, Claſs 20.

The ſpecies of *nerion* enumerated by Mr. Tournefort, are theſe: 1. The red-flowered *nerion*. 2. The white-flowered *nerion*. 3. The narrow-leav'd Indian *nerion*, with ſingle ſweet-ſcented flowers. 4. The broad-leaved Indian *nerion*, with ſweet-ſcented double flowers. 5. The broad-leaved Indian *nerion*, with ſweet-ſcented, double, variegated flowers: and, 6. The climbing American *nerion*, with tuberoſe briony-like roots. *Tourn* Inſt. p. 654.

NERITA, a genus of ſhell fiſh, of the nature of the ſemi-circular-mouth'd cochleæ, and comprehended under the general term *cochlea ſemilunaris*. See Tab. of Foſſils, Claſs 9. and SEMILUNARIS *cochlea*.

NEROPHIDION, in ichthyology, a name given by Schoneveldt, and ſome others, to that ſpecies of the *acus* or *ſyngnathus* of Artedi, which is called by that author the hexagonal-bodied *ſyngnathus* with the pinnated tail; and by others, the *acus Ariſtotelis*, and *acus ſecunda ſpecies*, and *typhle*; by ſome alſo, *blennus*.

NERVE (*Cycl.*) — The antients found, that by cutting, tying or compreſſing any *nerve*, or any other way intercepting its communication with the brain, the parts to which it belonged were immediately deprived of all ſenſe and motion. One remarkable inſtance of this is, the making an animal dumb by tying the *nerves* near the wind-pipe. We read in Galen, of a boy who became quite dumb by having both the recurrent *nerves* divided.

The experiment of cutting theſe *nerves* in brute animals, was repeated and confirmed by Veſalius; and Dr. Martin aſſures us, he tried it ſucceſsfully on a pig; nor did the animal recover its voice, as ſome have ſuſpected it might. As the voice depends on a proper aperture of the glottis, it ſeems likely that when the recurrent *nerves* are cut, the glottis will always ſtand open, and be incapacitated from being ſhut at the will of the animal. See Med. Eff. Edinb. Vol. 2. Art. 8.

An anonymous phyſician offers what he calls an *experimentum crucis*, in proof of the *nerves* being compoſed of cylindrical canals, containing a fluid: it is the demonſtration of the optic *nerve* inflated and dried, which appears canular to the naked eye. See Preſent State of Rep. Let. Vol. 12. Art 16.

Wounds of the NERVES. Upon the diviſion of a *nerve*, the limb to which that *nerve* was extended becomes inſtantly rigid, void of ſenſation, and withers: ſo that it is no wonder that a man inſtantly expires, upon the diviſion of thoſe nerves which are ſent to the heart or diaphragm: a wound alſo is attended with great danger where the *nerve* is only partially wounded, and not entirely divided; for the wounded fibres contract themſelves, and thoſe which remain undivided ſuffer too great extenſion, which will bring on moſt violent pain, ſpaſms, convulſions, inflammations, and gangrenes, and ſometimes death itſelf. *Heiſter*'s Surg. p. 27.

NERVES *microſcopically examined*. Mr. Leuwenhoek endeavoured by his microſcope, to diſcover the ſtructure of the *nerves* in the ſpinal marrow of an ox: he ſaw there with great delight, minute hollow veſſels of an inconceivable firmneſs, inveſted with their proper membrane, and running out in length parallel to one another, and making up their compoſition: and tho' ſome hundreds of theſe veſſels go to the formation of the leaſt *nerve* that can be examined, he not only diſcerned the cavities in them, which he computed to be three times leſs than their diameters, but in ſome perceived the orifices as plainly as the holes in a pricked paper are to be ſeen when looked at againſt the ſun. It requires, however, great dexterity and expedition to make this examination with ſucceſs; for after a thin ſlice of the ſpinal marrow is placed before the microſcope, in leſs than a minute's time it becomes dry, and the whole appearance vaniſhes. *Baker*'s Microſcope, p. 145.

NERVOSE *leaf*, *nervoſum folium*, among botaniſts. See LEAF.

NESTLINGS, a name given to Canary birds brought up by hand. See CANARY and PASSERES *Canarienſes*.

NET (*Cycl.*) — The taking fowls by *nets* is the readieſt and moſt advantageous of all others, where numbers are to be taken.

The making the *nets* is very eaſy, and what every true ſportſman ought to be able to do for himſelf. All the tools neceſſary to it are wooden needles, of which there ſhould be ſeveral of different ſizes, ſome round, and others flat; a pair of round-pointed flat ſciſſars, and a wheel to wind off the thread. The packthread is to be of different ſtrength and thickneſs, according to the ſort of birds that are to be taken; and the general ſize of the meſhes, if not for very ſmall birds, is two inches from point to point.

The *nets* ſhould be made neither too deep nor too long, for they are then difficult to manage; and they muſt be verged on each ſide with twiſted thread. The natural colour of the thread is too bright and pale, and is therefore to be altered in many caſes, according to the occaſion.

The moſt uſual colour is the ruſſet: this is to be obtained by plunging the *net*, after it is made, into a tanner's pit, and letting it lie there till it be ſufficiently tinged; this is of a double ſervice to the *net*, preſerving the thread very greatly, as well as altering the colour. The green colour is given by chopping ſome green wheat, and boiling it in water, then ſoaking the net in this green tincture till it have ſufficient colour. The yellow colour is given in the ſame manner, with the decoction of celandine: this gives a pale and faint ſtraw colour, which is the colour of ſtubble in the harveſt time, and is juſt what is wanted. The brown *nets* are intended to be uſed on ploughed fields; the green on graſs grounds, and the yellow on ſtubble lands.

Great care is neceſſary in the preſerving of *nets*; and the principal thing to be conſidered in regard to this is, that all wet rots the threads: whenever they have been uſed in dew or rain, they muſt be hung up to dry in the ſun; and if there is any rent or breach made, it muſt be mended as ſoon as it is diſcovered. In the drying, they muſt be hung as far as may be from the walls, that they may be out of the way of mice and rats, which are very apt to deſtroy them. The utmoſt depth that ſhould be allowed to a *net* for fowl, is two fathom, and the utmoſt length ſix fathom.

The places for uſing fowling *nets* to moſt advantage, are the morning and evening haunts where the birds come to feed. The ſportſman is to be at the place at leaſt two hours before the time of their coming, and the *net* muſt immediately be

ſpread flat and even upon the ground, and the two ends faſtened down with ſtakes. At the lower part there is to be a long cord fixed to the upper edge of the *net*, by means of which it may be immediately raiſed, and pulled over. The ſportſman is to hide himſelf behind ſome natural or artificial ſhelter, at the extremity of this line, and ſome cut graſs muſt be ſtrewed all over the *net* as it lies on the ground, to hide it from the fowl; and ſome live bird, that has been taken before, ſhould be ſtaked down before the *net*, by way of a ſtall, to draw in the others.

As ſoon as a ſufficient number of birds are within the compaſs of the *net*, it is to be pulled ſwiftly over them, and the fowler having taken thoſe that are under it, may ſtake down two or three more live ones, and ſpread the *net*, covering it with graſs as before. This ſort of ſport may be continued from as ſoon as it is light in the morning till an hour after ſun-riſe; but after that time, the birds have done feeding ravenouſly, and the ſport is over for that day.

Cinque-port NET, in fiſhery, a name given to a ſort of ſquare *net*, reſembling a cage, and having five entrances into it, from whence it has the name.

It is a very ſerviceable *net* in any pond or river, and is equally good in ſwift or ſtanding water. In order to make this *net*, there muſt be provided four large and ſtrait poles, anſwerable in length to the depth of the water. The ends of theſe muſt be ſharpened in the manner of ſtakes, and there muſt be notches within a foot of the ſharp part to faſten the *net* to, and at a convenient diſtance, on the poles, there muſt be another ſet of notches, for the faſtening the other ends of the *net*.

The bottom of this *net* is four-ſquare, without any entrance. A boat muſt be taken out with this *net*, to place it properly. The four poles muſt be fixed in the bottom in ſuch a manner, that each may anſwer to the other in a direct line; and they muſt ſtand at ſuch diſtances, that the *net* may be drawn out as ſtiff as poſſible between them. If the *net* is to be fixed in a ſtanding water, this method alone will do very well; but if it be a ſmooth ſtream, ſomething more is neceſſary, otherwiſe the motion of the water will keep the *net* playing about, and this will frighten away the fiſh. To prevent this, four ſtrong ſticks are in this caſe to be faſtened along the tops of the others, ſo as to make a ſort of frame, to ſtreighten and ſtrengthen the others, and keep all tight.

When the *net* is perfectly fixed, it repreſents a cage, and the ſides, top, and bottom are kept ſo firm, that the fiſh do not regard them, but ſeem to take them for weeds; but going in at the entrances, there is no returning, and in rich places great numbers are taken.

Crow NET, in birding, a name given to a ſort of *net* contrived for the catching of wild fowl in the winter ſeaſon.

This *net* may be uſed in the day-time, and is to be made of double thread, or of fine packthread, and the meſhes are to be two inches wide. The length of the whole ſhould be about ten yards, and the depth about three. It ſhould be verged on the ſides with a ſtrong cord, and ſtretched out in length very ſtiff upon long poles, prepared for that purpoſe. When this *net* is brought to the place where it is to be uſed, it muſt be opened, and ſpread at full length and breadth: then its lower end is to be faſtened all along the whole length to the ground, ſo that it only can be moved up and down. The upper end of the *net* muſt ſtand extended on the long cord, the farther end of it being firſt ſtaked to the earth by a ſtrong cord, about five yards diſtant from the *net*, and ſtanding in an even line with the bottom of the *net*. The other end of the cord muſt reach at leaſt five and twenty yards, to ſome natural or artificial ſhelter, by means of which the ſportſman is to lie concealed from his prey. The *net* muſt be placed in ſuch exact order, that it will play upon the leaſt jerk of the cord, and that muſt always be given ſuddenly, leſt the prey eſcape. This *net* is principally uſed for crows and pigeons, on new-ſown corn fields, and it may alſo be uſed in ſtubble fields, where the ſtubble will hide the *net* from the fowl. If the meſhes are made ſmaller, it may be uſed at barn-doors and the like for ſmall birds, and a bait of chaff will bring them together under it. But the great uſe of the *crow-net*, is to ſpread it in mornings and evenings where the haunts of wild fowl are, which in hard weather fly in great flocks to and from land, with and againſt the wind, and then fly cloſe to the ground, in open countries and low lands, where there are few hedges. When a whole covey of theſe are within the reach of the *net*, it is to be let go over them, and they will be taken in great numbers at one caſt.

Tunnel NET. See the article TUNNEL.

Wolf NET. See the article WOLF.

NETE, *(Cycl.)* in the antient muſic, was a general name for one of the extreme chords of a tetrachord. Some ſay it was the higheſt, and others the loweſt ſound. But perhaps the truth of the matter is, that it was the higheſt or loweſt ſound, according as the aſcending or deſcending ſcales were conſidered. Vid. Phil. Tranſ. N° 481. p. 269. See HYPATE.

When the *nete* is ſaid to be one of the extremes of a tetrachord, it is to be underſtood of a tetrachord conſidered by itſelf: for, when tetrachords were combined, the *nete* ſometimes took another name, as appears from the Greek ſcale inſerted under the article DIAGRAM. Vid. *Wallis* App. ad Ptol. Harm. p. 158.

NETHINIMS, among the Jews, the poſterity of the Gibeonites, who were condemned by Joſhua to be hewers of wood and drawers of water for the houſe of God. *Hofm.* Lex. in voc. *nethinæi*. *Joſ.* ix. 22.

NETOPION, Νετωπιον, a name given by the antients to a very fragrant and coſtly ointment, conſiſting of a great number of the fineſt ſpicy ingredients. Hippocrates, in his treatiſe of the diſeaſes of women, frequently preſcribes the *netopion* in diſeaſes of the uterus; and in other places he ſpeaks of its being poured into the ears as a remedy for deafneſs, theſe compoſitions, by their attenuating qualities, dividing the viſcous and thick humors The word *netopion* is alſo ſometimes uſed to expreſs the *unguentum Ægyptiacum*, and ſometimes ſimply for oil of almonds.

NETTINGS, in a ſhip, are a ſort of grates made with ſmall ropes, and ſeized together with rope-yarn, and are laid in the waſte of a ſhip, ſometimes, to ſerve inſtead of gratings. See GRATINGS.

NETTING-*ſail*, in a ſhip. See the article SAIL.

NETTLE, in botany. See the article URTICA.

Dead NETTLE. See the article LAMIUM.

NETTLE-*tree*. See the article CELTIS.

NEURADE, in botany, a name given by Linnæus to a genus of plants, called by Juſſieu *tribulaſtrum*. The characters are theſe: the perianthium is very ſmall, and ſtands upon the germen of the piſtil: it is compoſed of one leaf, divided into five ſegments. The flower conſiſts of five equal petals, larger than the leaves of the cup: the ſtamina are ten filaments, of the length of the cup: the antheræ are ſimple: the germen of the piſtil ſtands under the cup, and is of a gibbous figure: the ſtiles are ten in number, and are of the length of the ſtigmata: the ſtigmata are ſimple. The fruit is an orbicular capſule, of a depreſſed figure on the ſurface, and convex underneath, and is every way ſurrounded with prickles. The inner part is divided into ten cells, in every one of which is lodged a ſingle ſeed. *Linnæi* Gen. Plant. p. 185.

NEURIS, in the writings of the antients, the name given to a ſpecies of marble, otherwiſe called *elaphoncſum*, and *proconneſium*. It was much uſed by the Roman ſtatuaries, and was dug in a ſmall iſland that lay between Paros and Cyzicus. It was of a duſky or blueiſh white, and was variegated with fine and ſlender veins of black, often beautifully diſpoſed, and in the bodies of the naked ſtatues reſembling the courſe of the veins.

NEUROBATES, in antiquity, a rope-dancer. See the article DANCE, *Cycl.*

NEUROPHYLLON, in natural hiſtory, a name given by Mr. Lhuyd to a ſpecies of foſſile plant, remarkable for the ridges on the leaf. See *foſſile* PLANT.

NEUTHA, a name given by authors to a pellicle covering the eyes or the ears of a child in the birth, and ſometimes the whole face.

NEVEW, in botany, &c. See NAPUS.

NEWT, or EFT, in zoology. See the article EFT.

The land *newt*, or as naturaliſts often call it, the land *ſalamander*, has ſomething very remarkable in its outer coat. Its ſkin often appears dry, like that of the lizard kind, but often alſo it appears wetted, and as if covered with a fine ſhining varniſh: the change from one to the other of theſe ſtates is uſually performed in an inſtant, and it frequently becomes immediately wet all over on the touching it. It alſo contains, under the ſkin, a ſort of milky liquor, which ſpurts out to a diſtance on preſſing the body of the animal.

The paſſages for this milk are a vaſt number of pores or holes, many of which are plainly viſible to the naked eye; and very probably the firſt-mentioned liquor, which covers the ſkin in manner of a varniſh, may be the ſame with this, its white colour not being diſtinguiſhable when it is ſpread ſo thin over the ſurface of the animal. This milk reſembles very much the milky juice which the tithymals, and many other of the ſucculent plants, afford on being cut or broken. It is of an inſupportably acrid and ſtyptic taſte; and tho' the tongue receives no injury from touching it, yet the ſenſation is ſo violent, that one is apt to imagine there muſt be a wound made in it. This animal, when bruiſed, yields alſo a very diſagreeable ſmell.

It has generally been ſuppoſed, that this animal is of a poiſonous nature; and the famous ſalamander of the old writers ſeems to be of the ſame genus, if not the ſame animal. Mr. Maupertuis, determined to inform the world of the truth in regard to theſe remarkable particulars, cauſed a large number of theſe animals to be brought to him, which the country people, who had caught them about the bottoms of old walls, brought to him with as much caution as if they had been vipers.

The firſt experiment he made, was that of the incombuſtible quality of this animal: to this purpoſe he threw ſeveral of them into a common fire; moſt of them periſhed immediately, but a few made ſhift to crawl out; but theſe could not get away on a ſecond trial, but periſhed like the reſt. It was obſerved, however, that the moment they were thrown into the fire,

fire, the whole quantity of milky juice they contained was driven out at all the pores, and drying in an instant, stood in round globules, like so many pearls, till wholly consumed by the heat.

It is possible that the observing this creature to have a power of throwing out these juices, and covering itself at pleasure with wet, might give rise to the imaginary property of its subsisting by the same means unhurt in the fire.

This trial being made, the next was to be certainly determined whether the creature were poisonous, or not. This Mr. Maupertuis proposed to try two ways; the first by making the creature bite some animal; the other by making some other creature eat the *newt*. But these experiments were attended with more difficulties than might have been imagined, for it was neither easy to make it bite any thing, nor to make any creature eat it. No provocation could make the *newt* bite, and when its jaws were opened by force, its teeth were found so small, and so placed, that they seemed rather intended to saw, or cut things to pieces, than to bite with; and when a chicken was brought to be bit, and the feathers removed from the part, the jaws had no force to make the teeth penetrate, and, when pressed together, the teeth rather broke, or were put out of their places, than entered the animal, so that it was necessary to take off the skin, and the chicken then received several wounds, by forcibly pressing the jaws of the *newt*, together with parts of the raw flesh between: after this the lips, and tongue, of a dog, and the tongue of a turkey, were bitten in the same manner by other *newts*. The animals were let loose, and not one of them received the least injury from the bite.

The following trial was made, whether the flesh of the creature, or its milky juice were poisonous, when received into the stomach. Several animals were kept hungry a considerable time, on purpose to make them eat the animal, but none of them would touch it, so well has nature defended this little creature by the acrid juice under its skin, of which other animals are warned, as by instinct, and refuse to swallow so disagreeable a repast. A dog was at length compelled to swallow a *newt* cut into several pieces, while alive, and a turkey was forced to swallow, in like manner, a small one. The dog's mouth was tied up for half an hour, and half an hour after they were untied, he vomited up the tail and the feet of the animal, and received no injury; nor did the turkey which swallowed the young one. After this, pieces of bread were soaked in the milky juice alone, and chickens were made to swallow them, and wounds inflicted with weapons dipt in the same juice, but no harm ever ensued to the creature from either.

From all these tryals, it appears very evident, that the stories of this creature's being poisonous, are as idle, and groundless, as those of its living in the fire.

One thing remarkable this gentleman observed in his dissections of the animal, which was, that he found in several of the females, at once clusters of eggs, and living young ones. The eggs formed clusters resembling those of the ovaries of birds, and the young ones were contained in two tubes, or long pipes, the coats of which were perfectly transparent, and the young ones were easily distinguished through them, and there were counted in one female fifty-four of these, all living and vigorous. Mem Acad Par. 1727.

NEXI, among the Romans, persons free-born, who, for debt, were delivered bound to their creditor, and obliged to serve him, till they could pay the debt. *Hofm.* Lex. in voc.

NEXT *taker*, among miners, is he that hath the next meer in possession. *Houghton's* compl. Miner in the Explan. of the Terms

NHAMBUGUACU, in botany, a name of the great American *ricinus*, or *palma Christi*. *Marggr.* p. 77. *Piso*, p. 180.

NHAMDIA, in zoology, the name of a fish caught in the rivers of many parts of America, and of a fine taste. It is of the anguilliform kind, and has a long and fat body, becoming smaller toward the tail; its belly is soft; its head flat; and its mouth of a parabolic figure, and armed with small teeth. It is usually of about eight or ten inches long; its eyes are small and prominent; and it has a beard composed of six filaments, four placed below, and two above; the last are much longer and thicker than the other four, and have a long furrow behind each. It has seven fins beside the tail; one of the back fins is thorny; the rest are covered with the common skin of the body, which is soft, and free from scales. Its tail is forked, and its head is covered with a strong shelly coat; this is of a dusky brown. Its back and sides are of a bluish grey; the larger back fin is of the same colour; all the rest are black; and, on each side, there is a red line reaching lengthways from the gills to the tail. *Willughby's* Hist. Pisc. p. 140.

NHANDIROBA, in botany, a name given by Plumier to a genus of plants, the same with the *fevillea* of Linnæus. *Plumier*, Nov. Gen. 27. See the article FEVILLEA.

NHANDUAPOA, the name of a Brasilian bird, called also *jabiruguacu*, but more frequently known by its Dutch name *scurvogel* See SCURVOGEL.

NHANDUGUACU, in zoology, the name of a Brasilian bird of the emeu, or cassowary kind, but smaller than the common, or African cassowary. Its body is considerably large; its neck long and strong; its legs very long and thick; its wings extremely short, and unfit for flying, but assisting it in running; its feathers are grey, and, on the back, are considerably long. It commonly carries its neck bent like a swan; its head is shaped like that of a goose; its back feathers cover the rump, and make a sort of tail; it runs as swift as a greyhound, and feeds on flesh and fruits. *Marggrave's* Hist. Bras.

NHAQUUNDA, in zoology, the name of a small fish caught in the American rivers. Its body is oblong, and every where nearly of the same thickness; its head and mouth are like those of the pike; and its usual length is about four inches. It can extend its upper lip, and round the opening of its mouth. It has no regular teeth, but its jaws are rough like a file. It has two fins at the gills, two on the belly, one long one on the back, but not reaching from head to tail, and one short, and almost square one, behind the anus. Its tail is covered with a hard shelly crust; its body is covered with moderately large scales; and its back and sides are of a silvery grey; its belly white It has on each side a single row of round black spots, of the bigness of a pea, and among these a number of small blue ones. The fins also are all variegated with blue spots, and it has a long streak reaching from the gills almost to the tail, and under the end of that another short one which runs into the substance of the tail; these are both raised above the surface of the rest of the body, and are of a fine gold colour. It is a very well tasted fish. *Marggrave's* Hist. Bras.

NICETERIA *Athenæ*, Νικητήρια Ἀθηνᾶς, in antiquity, an Athenian solemnity in memory of Minerva's victory over Neptune, when they contended which of them should have the honour of giving a name to the city afterwards called Athens. *Potter*, Archæol. T. 1. p. 416.

NICHILIANISTÆ, in church history, heretics who maintained that Christ had no being. *Hofm.* Lex. in voc.

NICOL, in natural history, a word used by the miners in Germany to express a greenish crust, covering several of the species of marcasites and cobalt; it emits fumes that smell of garlick in the calcination, and is very injurious to the workmen, causing contractions of their limbs, and other disorders. It is sometimes found in masses alone, but that more rarely.

NICOMIA, in natural history, a name given by some to a stone called by others *chert* and *ubern*. It is of a greyish, horny constitution, and has veins of red on it. It is very hard and semi-pellucid, much resembling the common agates, and it gives fire readily with steel. It lies in strata in Yorkshire, and many other parts of England: these strata are about three foot thick, and run a vast way among the rocks. It usually lies among lime stone, and is not regular in colour, being sometimes of a dusky or blackish hue, like the common flint. It is so hard that no common tool will touch it, and it breaks irregularly, and without any grain, in the manner of the common flint. *Woodw.* Cat. Foss. Vol. 1. p. 22. See CHERT.

NICOTIANA, *tobacco*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the infundibuli form kind, consisting of one leaf divided into several segments at the edges; the pistill arises from the cup, and is fixed in the manner of a nail to the hinder part of the flower; this afterwards becomes a membranaceous fruit, of a roundish or oblong figure, divided by an intermediate membrane into two cells, which contain a large number of seeds fixed to a placenta. *Tourn.* Inst. p. 117.

The species of *tobacco* enumerated by Mr. Tournefort are these: 1. The great, broad-leaved *tobacco*. 2. The great, narrow-leaved *tobacco*. 3. The great broad, and round-leaved *tobacco*. 4. The small *tobacco*, called *priapeia* by some writers. 5. The white-flowered, thorny, tree *tobacco*.

NIDDUI, in the Jewish customs, is used to signify, separated, or excommunicated. This, according to some, was to be understood of the lesser sort of excommunication in use among the Hebrews. He that had incurred it was to withdraw himself from his relations, at least to the distance of four cubits: it commonly continued a month. If it was not taken off in that time, it might be prolonged for sixty, or even ninety, days. But if, within this term, the excommunicated person did not give satisfaction, he fell into the *cherem*, which was a second sort of excommunication; and thence into the third sort called *schammatha*, the most terrible of all. *Calmet* Dict. Bibl. in voc.

NIDUS *avis*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the polypetalous, anomalous kind, and is composed of six dissimilar leaves, the five upper of which are so disposed, as, in some measure to resemble an helmet; the lower one is headed, and bifid at the end. The cup finally becomes a seed vessel, containing seeds of a very remarkable smallness, and appearing only as dust. The roots are fibrous, and so interwoven together as to resemble a bird's nest.

There is only one known species of this genus, which is the plant called by many *orchis abortiva fusca*, the brown, abortive orchis. *Tourn.* Inst. p. 137.

NIEKE *corondi*, in the language of the Ceylonese, the name of a species of cinnamon. The tree which produces it resembles the *nieke*, another tree very common there. This is

a very bad kind of cinnamon, and has very little tafte or fmell. It is very feldom fold as cinnamon, but is much in efteem among the natives for its medicinal virtues. They obtain a water, and an oil from it, by roafting, which they anoint themfelves with, to preferve them from noxious fumes, and infections of any kind; and ufe the expreffed juice of the leaves to cool the head, and ftrengthen the brain, rubbing it on externally. Phil. Tranf N° 409.

NIGELLA, in botany, the name of a genus of plants, the characters of which are thefe: the flower is of the rofaceous kind, confifting of feveral petals arranged in a circular form, and ornamented with a fort of corolla between thefe and the ftamina, made up of a fort of horn-like bodies. The piftil arifes from the center of the flower, and finally becomes a membranaceous fruit, of a roundifh, or oblong, form, and often divided into feveral parts.

The fpecies of *nigela* enumerated by Mr. Tournefort are thefe: 1. The horned, field *nigella*, called by many authors *melanthium*. 2. The horned, field *nigella*, with blue double flowers. 3. The horned, field *nigella*, with white flowers. 4. The broad-leaved *nigella*, with large, fingle, blue flowers. 5. The narrow-leaved *nigella*, with large, fingle, blue flowers. 6. The narrow-leaved *nigella*, with large, fingle, white flowers. 7. The great, double, blue-flowered *nigella*. 8. The *nigela* with fmall, fingle, white flowers. 9. The *nigela* with fmall, double, white flowers. 10. The Cretic *nigella*. 11. The broad-leaved, fweet-fcented, Cretic *nigella*. And, 12. The *nigella* with fingle, pale, red flowers. *Tourn* Inft. p. 258.

We have feveral fpecies of this plant propagated in the gardens about London: they are all raifed by fowing the feeds in the fpring, on a bed of light earth, where they are to remain; and, when they come up, they are to be thinned to proper diftances, and kept clear from weeds. *Miller's* Gard. Dict.

NIGHT (*Cycl.*) — NIGHT *angling*, a method of catching large and fhy fifh in the night. Trout, and many other of the better forts of fifh, are naturally fhy, and fearful; they therefore prey in the night, as the fecureft time.

The method of taking them on this plan is thus: the tackle muft be ftrong, and need not be fo fine as for day-fifhing, when every thing is feen; the hook muft be baited with a large earthworm, or a black fnail, and thrown out into the river; there muft be no lead to the line, fo that the bait may not fink, but be kept drawling along, upon, or near, the furface.

Whatever trout is near the place will be brought thither by the noife, and motion of the water, and will feize the worm, or fnail. The angler will be alarmed by the noife which the fifh makes in rifing, and is to give him line, and time to fwallow the hook; then a flight twitch fecures him. The beft and largeft trouts are found to bite thus in the night, and they rife moftly in the ftill and clear deeps, not in the fhallow fwift currents. Sometimes though there are fifh about the place, they will not rife at the bait; in this cafe, the angler muft put on fome lead to his line, and fink it to the bottom. Dict. Ruft. in voc.

NIGHT-*fhade*, in botany. See SOLANUM.

NIGHT-*walkers*. See NOCTAMBULATIO, and NOCTAMBULI.

NIGHTINGALE, *philomela*, in zoology. See PHILOMELA.

Virginian NIGHTINGALE, in zoology, the common, but improper, name of a bird of the grofs-beaked kind, called by authors the *coccothrauftes Indica criftata*.

It is a little fmaller than our blackbird; it has a black ring furrounding the eyes, and noftrils; the beak is very large and thick, but not altogether fo large as in the common grofs-beak; and its head is ornamented with a very high, and beautiful creft, which it moves about very frequently. It is all over of a very fine, and lively red, but paler on the head and tail than elfewhere. It is brought to us from Virginia, and is much valued in England, for its beauty, and delicate manner of finging. It is very fond of almonds, and the like fruits. *Ray's* Ornithol. p. 179.

NIGRITIES *offium*, among the antients. See CARIES.

NIL, in botany, a name given by the Arabians to two very different feeds, which are often, by this means, miftaken in their writings, one for the other. Avifenna tells us firft that *nil* is the feed of a creeping plant, of the bindweed kind, and that this plant had blue flowers, like the campanulas, or bell-flowers. But, in another place, he tells us that *nil* is the name of a plant ufed in dying, which feems to be the fame with our *ifatis*, or woad. They fometimes call this plant, and fometimes the paint prepared from it, by the name *nil*. The old interpreters of Diofcorides into the Arabic have every where tranflated the word *ifatis*, or woad, by the word *nil*, or the vegetable of which *nil* was made. The interpreters of the Arabians have been all mifled into errors by the double fenfe of the word *nil*, and have too often tranflated what is faid of the *nil*, as a dye, or paint, to belong to the feed; and what is faid of the feed by authors, is, by them, interpreted fo as to be expreffed of the *ifatis*.

Avifenna ufes the word *ufme*, as a name of the leaf of *nil*: this is to be always underftood as meaning that *nil* which is ufed in dying; and, after this, he has a felect chapter on the *ifatis*, under this name *nil*. It is probable that the convolvulus, or bindweed, called *nil*, obtained this name only from its flowers being of the fame colour with the fine blue pigment obtained from the other *nil*, or woad.

NILACUNDI, in natural hiftory, a name given to a ftone of the gem kind, which is half a fapphire, and half a ruby. See SAPPHIRE, and RUBY.

The word *nilaa* is the Indian name for the fapphire, derived from the word *nil*, the name of indigo, and given to this gem becaufe of its fine blue colour, which approached to the tinge of that pigment. The latter part of the word is not eafily accounted for, without making a little variation in the fpelling, but, with that, is very clear and eafy. *Jacut*, or *ja uti*, and, as fome fpeak it, *ja unti*, is the name given by the Indians to the ruby, and it is only fuppofing the word to be properly *nil-ja unti*, and it expreffes in their own language, exactly what we underftand by it, a ftone, part fapphire, and part ruby.

NILAHUMATU, in botany, a name given by feveral authors to the fmooth fruited *ftramonium* of Malabar. See the article STRAMONIUM.

NILIACUM *mel*, a name by which the antients expreffed the very fineft honey.

NILICANARAM, in botany, the name by which fome authors call the tree whofe fruit is the myrabolan ufed in medicine. Hort. Mal. Vol. 1. p. 69.

NILUFAR, in botany, a name given by the antient writers to the common *water-lilly*. They diftinguifhed this plant by that name from the Indian *nymphæa*, whofe root was of a cold and foporific virtue, like that of the mandrake. This they call always *nenufar*. The word *nilufar* afterwards gave rife to another name *linufar*: this was only formed of the fame letters a little tranfpofed, and was ufed to exprefs all the kinds of the *water-lilly*. The Greeks borrowed the word *nilufar* of the Arabians, and, at firft, wrote it *nilafaran*, but afterwards it became contracted into *noufaran*, and fo it ftands, at this time, in moft of the works of the modern authors of that nation. Neophytus runs into great errors on this account, and confounds together the trifoliate lotus, with the lotus of Ægypt, the leaves of which are like thofe of the *nymphæa*, or the *arum*.

Some writers have fuppofed the *andrafa e* to be a kind of *nilufar*, and to have been defcribed as fuch by the antients, and others have thought the fame of the *ftratiotes*; but all this is without foundation. Thefe plants are wholly unlike both to the *nymphæa*, and to one another, and were never confounded, either together, or with that plant, except in the brain of fuch authors.

NIMBUS, among the Romans, a fcarf embroidered with gold, which women wore on their foreheads.

NIMBUS was likewife ufed for the money thrown among the people, upon any public occafion. *Pitifc.* Lex. Ant. in voc.

NINTIPOLONG, in zoology, the Ceylonefe name of a fpecies of ferpent called alfo *ferpens hypnoticus*. It is a very poifonous fpecies, and its bite brings on a fleep upon the perfon, which terminates in death. It is of a deep, blackifh brown, variegated with fmall fpecks of white. *Ray's* Syn. Anim. p. 332.

NINZIN in the materia medica, a name ufed by fome authors for the famous Chinefe root, commonly called *ginfeng*. See GINSENG, *Cycl.*

NIPPERS, in the manege, are four teeth in the forepart of a horfe's mouth, two in the upper, and two in the lower jaw. A horfe puts them forth between the fecond and third year. See TEETH.

NIPPERS is alfo an inftrument in ufe among fmiths, and farriers, being a kind of pincers, wherewith, in fhoeing an horfe, they cut the nails before they rivet them. It is alfo ufed in taking off a fhoe.

NIPPERS, in a fhip, are fmall ropes about a fathom, or two, long, with a little truck at one end, and fometimes only a wale-knot. Their ufe is to help to hold off the cable from the main, or jeer capftan, when the cable is fo flimy, fo wet, or fo great, that they cannot ftrain it to hold it off with their bare hands.

NIPPLES (*Cycl.*) — The *nipples* of women, in their firft lying in, are frequently fo fmall, and funk into their breafts, that the infant cannot get at them to fuck its nourifhment. The readieft method in this cafe is to apply an infant fomewhat older, and which can draw ftronger; or, if this does not fucceed, to let a woman who has been practifed in the art, attempt to fuck.

When thefe do not fucceed, it is common to have recourfe to a glafs pipe, and the poorer people in fome places ufually make a tobacco pipe ferve the turn. Others apply a fmall cucurbite made of ivory in the form of a hat, which they fuck ftrongly in their mouth. The common fucking-glafs is alfo, when properly applied, of very fignal fervice. To do this, the fmall hole at the fide is to be ftopped with wax, and the glafs heated with warm water; or, by holding it before the fire, fo as to rarify, and in part, expel the air. It is then to be applied to the *nipple*, which, in this cafe, will not only be pulled

out, but will discharge a large quantity of milk, so as to take down the inflammation and tumor in the breast. When the sucking power of the glass is grown weak, the hole at the side is to be opened, and the milk poured out; the glass is then to be heated again, and the hole being stopped again, is to be a second time applied, and so on, till the intention is fully answered. *Heister's* Surgery, P. 2. p. 11.

NIPPLE-*wort*, in botany, &c. See LAMPSANA.

NIQUI, in zoology, the name of a fish of the cucullus kind, approaching to the figure of that species commonly called *draco*, and *araneus marinus*, and in English the *weever*. Its head is large and thick, and its mouth large and without teeth. The under jaw is longer than the upper, and the anterior part of the body is somewhat broad, and flatted; the hinder part, especially toward the tail, is rounded. Its usual length is four or five inches; the eyes are small, but they are placed, like those of the crab, out of the head. It is covered with a mixt colour of brown, black, and yellow on the back and sides, and is white on the belly; it is spotted all over the head, back, and sides, with small black spots as big as poppy seeds. It is common about the American shores, and is eatable when the liver and gall are taken out, otherwise it is said to be poisonous. *Marggrave's* Hist. Bras. See Tab. of Fishes, N° 49.

NIR, in the materia medica, a name given by the Arabian physicians to the pigment, or colour, made from the *isatis*, or woad. The word is derived from the Latin *nigrum*, black. The colour of this pigment is, indeed, not black, but a deep blue; but we find numerous instances of the Greeks and Latins, both using the proper appellatives of black for the same colour, a deep blue. We find Theophrastus calls the fine deep blue oriental sapphires black, μέλανας, and Virgil expresses the deep blue of the violet by the word *nigra*. Many of the Arabians call this plant, and the pigment, or colour, made from it, by the name *nil*, but that is a less determinate name, as they call also the seed of a kind of bindweed with blue flowers by the same name. See NIL.

NISAN, a month of the Hebrews, answering to our March, and which sometimes takes from February, or April, according to the course of the moon. It was made the first month of the sacred year at the coming out of Egypt. *This month shall be unto you the beginning of months, it shall be the first month of the year to you.* Exod xii. 2.

It was the seventh month of the civil year. Moses calls it *abib*. The name *nisan* is only since the time of Ezra, and the return from the captivity of Babylon. *Calmet* Dict. Bibl.

NISSOLIA, in botany, the name of a genus of plants, the characters of which are these: the flowers, and fruit, are the same with those of the lathyrus, but the leaves stand single, and the stalks have no claspers, or tendrils at their ends. There is only one known species of *nissolia*, which is the plant called by some the small, one-leaved *lathyrus*. *Tourn.* Inst. p. 656.

NISUS, in zoology, a name by which many authors call the *accipiter fringillarius*, or sparrow-hawk. *Ray's* Ornithol p. 51. See the article FRINGILLARIUS *accipiter*.

NISUS is also a name used by some old naturalists for the *haliaetus*, or *aquila marina*, called in English the *sea eagle*, or *osprey*. *Willughby*, Ornithol p. 29.

NISUS is likewise a name given by the barbarous writers of the middle ages to *alabaster*.

NITEDULA, in zoology, the field mouse. See MUS.

NITIDUM *folium*, among botanists. See LEAF.

NITRE (*Cycl.*) — NITRE is a salt found immersed in imperceptible particles, in earthy substances, as the particles of metals in their ores, and is discoverable in these bodies by an acrid and pungent taste, and a sensation of coldness with which it affects the tongue: sometimes also it is found native, and pure, in form of an efflorescence, or shapeless salt, either on its ore, or on old walls, and yields, after solution, hexaëdral prismatic crystals.

Many have been of opinion that *nitre* was, in part at least, an animal salt, and that where it was found on old walls, it was owing to the effluvia of animal bodies once inhabiting the place; but we find it now in vast quantities in several of the marly earths of the East-Indies, and some other places, which, however, though they abound with it, when they are in the naked cliffs, exposed to the air in a proper situation, yet when dug up from any depths in the earth, the same substances are not found to contain any of this salt.

This marly earth is frequent in China, Persia, and many parts of the east, and is chosen for working from places where it stands in barren cliffs, on hills facing the northern, or eastern winds. The manner of their separating *nitre* from this earth, is as follows; they dig large pits, which they coat over on the inside with a stiff and firm clay; this they fill half full of water, and into it throw the earth. When the water has stood some days to imbibe the salt, they draw it off into other pits, defended by slight walls on all but the north-east side. Here the sun exhaling the water, the salt which it had imbibed, affixes itself to the sides of the pit in small, brownish, white, hexaëdral, but very imperfect crystals, which are what we receive from the East-Indies, under the name of rough *nitre*.

This is the way the greatest quantity of this salt is made, but it is also procured from divers other materials, and by many other methods. In many of the eastern nations, the ruins of old buildings exposed to the north-east winds, and sheltered from rain, have their walls covered with efflorescences of a nitrous salt, which is usually thrown with the earth into the *nitre* pit. Earths moistened with the excrements of animals as the earths of pigeon-houses, and the like, all afford more or less *nitre*, and, in France, vast quantities are annually made from lime rubbish, and the ruins of old buildings.

By which ever of these methods *nitre* is procured, it is ever in all respects the same salt. Its crystals are of a hexaedral prismatic form, terminated by hexaedral pyramids. It dissolves in a moderate fire, and does not flame, unless a coal, or some other sulphureous body fall in. It requires near seven times its own weight of water to dissolve it perfectly. *Hill's* Hist. of Foss. p. 393, 391, 395.

This salt gives the greatest of all proofs of the effects of synthetical, or recomposing chemistry. It is first separated, or analysed, in the following manner: take two pounds of refined saltpetre in fine powder; pour upon it one third of its weight of oil of vitriol, and distill it in a glass retort, in a strong sand heat, there will be produced a strong acid spirit of *nitre*, which cannot, by any experiment, be found to participate at all of the nature of the oil of vitriol used in its preparation. Then take a pound of fresh *nitre*, melt it in a crucible, and throw into it, at times, pieces of charcoal, till it will no longer keep in fusion with the same degree of fire; then encrease the fire, and melt it, and then pour it into a proper vessel; leave it to cool of itself. This is fixed *nitre*, and is an alkali: now dissolve this fixed *nitre* in water, and exactly saturate that water with the acid spirit of *nitre* before distilled, this compound liquor will, by standing, shoot into true and perfect crystals of *nitre*. And the experiment succeeds as well, if a solution of pot ashes, or any other fixed alkali, be used instead of that of fixed *nitre*. *Shaw's* Lectures, p. 170.

Of all the salts which afford us those strong liquors commonly known by the name of the mineral dissolvents, salt petre, or *nitre*, is the only one which yields red vapours, or whose spirit rises in form of red vapours, as soon as it is separated by means of fire; but the reason of this fact has never been accounted for, till Mr. Hellot explained it to the Academy at Paris, in one of his memoirs.

Of the chemists who have before treated of it, some imagined that the redness of the vapours was owing to some part of the sulphureous substances which the salt had imbibed from the urine and dung of animals where it was formed; others that this colour was owing to particles of fire carried up with the vapours in their ascent. But these are weak conjectures, since, if the first were the case, the mixtures of sal armoniac with common salt of vitriol, ought to yield red vapours in distillation, which never is the case; and, if the latter be supposed, it is not easy to say, why oil of vitriol does not arise in the same coloured vapours; since it requires a more violent, and longer continued fire to raise it.

Vitriol is added to *nitre* in the distillations which yield these red vapours, and it is the first point to be determined in the investigating this phænomenon, whether the vapours owe their colour truly to the *nitre*, or whether they borrow it from the additional vitriol. Baldwin, Stahl, and many others are of opinion indeed, that the red vapours are owing to the vitriol, and essential to it, and call them the *anima nitri*; and they prove the assertion by the known observation that *nitre* melted with a tender white glass, turns it to purple, or some shade of red; whereas neither alum, common salt, nor the fixed alkalis give this colour; and it is probably some portion of an ammoniacal urinous salt, mixed in the *nitre* which gives the colour, since sal armoniac will give the same colour when fused with glass. What is it, however, in the sal armoniac which has this effect? not its volatile alkali, for that is dissipated in the mixture by the first efforts of the fire; neither can it be the acid spirit of sea salt, since experiment proves that it can have no such effect, when employed alone.

A little crocus martis, or any calx of iron, does the same thing to glass, and sometimes even the smoak of the furnace will do it, when woods of too resinous a kind are employed as fuel; many a large quantity of what was meant for pure crystalline glass having been tinged red, or purple, in this manner, and wholly spoiled; and all that we can judge on the whole, as to *nitre*, or sal armoniac tinging them, is, that it is a fatty, or unctuous matter in those salts which produces the colour: and, in all probability, *nitre* contains, beside a quantity of an urinous, or ammoniacal salt, a small quantity of a ferrugineous matter, in extremely minute and imperceptible particles.

Mr. Lemery has proved that all the salt petre made in Europe has been originally an ammoniacal salt; and, indeed, if *nitre* be rubbed for a considerable time in a glass mortar made warm, with a quantity of a fixed alkali salt, it will afford an urinous smell. It is not easy to prove that all sal armoniac contains ferrugineous matter; but when we con-

ſider that iron is always found in the aſhes of vegetables, and that it, therefore, evidently aſcends in extremely minute particles, with the juices of plants; and that ſal armoniac is prepared from a ſoot made of the excrements of thoſe animals which feed on plants, we ſhall find it no impoſſibility that iron ſhould be there; and we well know that iron, in any ſtate, cannot but give that colour to glaſs, which *nitre*, in a ſmaller quantity, and ſal armoniac, in a larger, are able alſo to give. Memoirs Acad. Scienc. Paris. 1736.

All obſervations and experiments would ſeem to prove that the red colour given to glaſs by *nitre*, can only be owing to ferrugineous, or ammoniacal matter contained in it; and it is no very raſh conjecture, to ſuppoſe that the ammoniacal matter contained in the ſalt-petre, rarifying, and extremely dividing the ferrugineous matter, during the time of the diſtillation, may diſtribute them in their disjunct moleculæ, to all that matter, or thoſe particles, which form thoſe vapours, and tinge them red by its diſtribution of them.

It is to be obſerved, however, that the vapour of ſpirit of *nitre*, or of aqua fortis, are not always red, but only are ſo when the fire is great enough to raiſe with the vapours the matter which colours them; for if ſpirit of *nitre* be made with the addition of alum calcined, with dry ſalt-petre, and with filings of zink mixed together, there will be obtained with a ſmall degree of fire, a ſpirit of *nitre*, which does not come over in red fumes.

If the fire be raiſed to a greater degree of violence, there will afterwards be obtained a ſecond ſpirit of *nitre*, which will come over in red fumes; but the firſt of theſe will ſhew the great experiment of taking fire on mixture with oil of turpentine, or the European oils of vegetables, better and more readily than the other.

It is therefore no eſſential character of ſpirit of *nitre* to riſe in red vapours, ſince the firſt riſes without; and this is truly the pure ſpirit of *nitre*; while the ſecond, which riſes in red fumes, is impure, being coloured by ferrugineous, or other foreign matter raiſed in vapour with the reſt, by the great violence of the heat.

It is obſervable, that if vitriol calcined to a redneſs be uſed with the *nitre*, for drawing the ſpirit, the vapours riſe of a perfect blood red. In the common way of diſtilling what is called ſimply ſpirit of *nitre*, the cuſtom is to put into the retort with the ſalt-petre, a very large quantity of a vitriolic earth; and in the making that ſpirit called aqua fortis, green vitriol, or Engliſh copperas is mixed with the *nitre*. This is abundantly known to contain a great deal of iron. Here, therefore, is in each caſe a quantity of ferrugineous matter added; and we well know that this can give a red colour to the vapours, with which it is by violence of fire compelled to riſe. Repeated trials of ſpirit of *nitre*, with mercurial preparations alſo, prove beyond contradiction, that there is ferrugineous matter in that ſpirit. Many of the common mercurial precipitates, when made with aqua fortis, or with plain ſpirit of *nitre*, may have abſolute plain iron ſeparated from them; and the chemiſts know well that this is not to be ſuppoſed to have been lodged in the mercury, ſince it is very difficult to conceive how that metal ſhould become amalgamated with it; but there can be no difficulty of ſuppoſing it ſeparated from the menſtruum, ſince it is evident that there is iron contained in the matters uſed in the diſtillation of it, and even in the ſalt itſelf from which it is originally drawn.

It would be very natural to ſuppoſe that the ferrugineous matter was raiſed only from the additions of pure vitriol or a vitriolic earth; but it is evident from the experiment of *nitre* alone turning glaſs red, that there is certainly alſo ferrugineous matter in that ſalt itſelf; nor is it at all difficult to conceive how iron comes to enter the body of that ſalt; ſince, if we conſider it as made in Europe, from the rubbiſh of old buildings, and the cleanſings of ſtables, &c. it is eaſy to conceive that pieces of iron of ſeveral kinds may have been ruſted away, and conſumed there, and ſo mixed among the matter from which the ſalt was afterwards made. The addition of wood aſhes always uſed alſo in the making it, may have lodged ferrugineous matter among it, ſince it has been often proved that the aſhes of all vegetables contain true iron. Memoirs Acad. Scienc. Par 1736.

It may ſeem a difficult thing to conceive, however, in what manner ſo ſmall a quantity of iron as there can be ſuppoſed to be in *nitre*, is able to colour ſo large a body of vapours as are ſeen to riſe in the diſtillation. But if we conſider the extreme diviſibility of the particles of metals into colouring matter, and the vaſt quantity of water that a ſingle grain of copper is capable of tinging blue, when diſſolved in an alkali, we ſhall be the leſs ſurpriſed at it; eſpecially if it be conſidered alſo that it has been proved already that there is true ſal armoniac in all *nitre*, and it is well known that this ſalt is capable of rarifying, and extremely dividing the particles of that, or any other metal; and if as much ſal armoniac as can be diſſolved in aqua fortis be added to that ſpirit, it is well known alſo that it will make it ſend up vapours much redder than before, which can only be owing to the ſal armoniac raiſing a larger quantity than ordinary of the ferrugineous matter contained in the aqua fortis than would naturally have been raiſed from it.

The moſt ready way of reducing *nitre* to powder, is to diſſolve a quantity of it in as little water as may be, and evaporate the water over a gentle fire, continually ſtirring it till dry, by which means the *nitre* will be found in form of a very dry white powder. This is the method uſed by the gunpowder-makers. *Shaw's* Lectures, p. 389.

The curious, in the hiſtory of *nitre*, and its preparation from vegetables, &c. and the purifying it for gunpowder, and other uſes, may conſult the works of Glauber, Stahl, and Clark, on the ſubject of this ſalt, and compare them with the diſcourſe of the younger Lemery on the origin of *nitre*.

Purified NITRE. See NITRUM *purificatum*.

Spirit of NITRE. See SPIRITUS *nitri*

NITRIUM *ſal*, in natural hiſtory, a name given by many writers to the ſalt ſeparated from the water of the lake Natron in Ægypt, which is the *natrum*, or *nitre* of the antients.

This lake is ſituated in the Nitrian deſart, ſo called from *Nitria*, a very large town there It is ſix or ſeven acres in extent, and lies about thirty miles weſt and by ſouth from Terana, and about the ſame diſtance north from the pyramids: from the bottom of this lake the ſalt called *natrum* ariſes to the ſurface of the water, and is there condenſed, by the heat of the ſun, into the hard and dry form in which it is ſold.

Four ounces of the water of the Natron being examined by evaporation in a glaſs veſſel, placed in a ſand heat, there will ariſe, as ſoon as it becomes warm, a ſort of ſcum to the top; this being taken off, another inſtantly ſucceeds, and ſo on, ſo long as any water remains in the glaſs.

This ſalt, thus ſcummed off, is the ſame in all reſpects with the *natrum*, or the Smyrna ſoap earth; being a fixed alkali, fermenting with acids, and boiling into ſoap with oil. This icy ſcum is the ſame as that called by Pliny *flos ſalis*, and ſeems to be the ſame with that which Herodotus ſays the Ægyptians made uſe of in the preparation of their mummies.

It is ſaid that the water of this lake, though it contains ever ſo large a quantity of this ſalt, will not ferment with any acids, tho' the leaſt particle of the ſalt ſeparated either by a natural, or artificial heat, will ferment violently with any acid What the heat of the ſand furnace does in this experiment, the heat of the ſun does in the lake itſelf; and the ſingular circumſtance of the water of the lake not fermenting with acids, is confirmed by this, that a clear ſolution of the ſalt in common water will not ferment with them.

The antients have attributed great virtues to the ſalt of this lake; and this being called *nitrum*, as a ſhort name for *nitrium ſal*, we have had ſome who have ſuppoſed the ſalt which we call *nitre*, to be the ſame, and theſe people have wondered that they did not find the ſame virtues in our *nitre*.

The mineral waters of all parts of the world ſeem to contain more or leſs of this ſalt, and to owe their virtues in a great degree to it; and, probably, it might be no ſmall improvement to phyſic, to bring it more into the preſent practice. Molenbroch recommends it greatly in the ſtone; and it may be the more probably uſed, as all alkali ſalts are known to be good in that diſtemper. Some add to this, that it ſeems qualified to diſſolve ſtony ſubſtances, it being of ſo piercing and penetrating a ſpirit, that no rock, or ſtone is found about the lake from the waters of which it is procured. Phil. Tranſ. N° 160.

NITROAERIAL *ſpirit*, a term invented by Mayow; and ſince uſed by many others, to expreſs a very active principle in the air, cauſing great changes in the bodies abſorbing it and expoſed to it.

The acid ſpirit of nitre is produced partly by the air, and partly by a terreſtrial matter making up the reſt of the body of that ſalt. Mr. Boyle, in his experiments on flame and air, has abundantly proved this; and that igneous particles of the air reſide in nitre, is as certain a concluſion from the ſame principles: theſe conſtitute its moſt active part, and by theſe the flame of kindled nitre is produced.

The aërial particles of nitre are truly no other than the igneoaerial matter of it, and this aërial matter is evidently lodged in the acid ſpirit of it, not in the fixed ſalt. This acid ſpirit is, according to Mayow, compoſed of a terrene matter, which is flexile and humid, and of etherial particles, which are rigid and dry, active and igneous, and proceeding from the air.

Theſe igneous particles are common to nitre and to air, and are therefore called *nitroaerial*; and the ſpirit of nitre derives, according to this ſyſtem, from theſe particles its active and corroſive quality, which makes it a ſort of potential fire; and on this the form of nitre chiefly, if not only depends.

Now as this *nitroaërial* or igneous ſpirit reſides in the acid ſpirit of nitre, it is thence inferred, that the *nitroaërial* ſpirit is of a nitro-ſaline nature, obtaining rather the nature of an acid than a fixed ſalt; conſidering alſo, that the effects of fire in general anſwer to thoſe of a very ſubtle and corroſive ſalt. Fire in general, on theſe principles, is eaſily proved to depend principally upon the ſaid *nitro-aërial* principle put into motion.

This *nitro aërial* ſpirit makes the moſt active, and, indeed, the principal part of the ſalt which we call *nitre* Its terreſtrial and acid parts make up the reſt of the maſs; and theſe are rather of uſe

ufe to form the whole into a body, and give it form and confiftence, than to add to any of its fat.

NITRUM, is ufed by the poet Martial to exprefs that fort of foulnefs in cryftal, which Pliny, and other of the antient Roman authors, diftinguifh by the name of *fal*. See the article SAL.

NITRUM *antimoniatum*, in chemiftry, the name of a falt procured by evaporating the filtrated waters ufed in making the *antimonium diaphoreticum* to a drynefs, continually ftirring them towards the end of the operation. There, at length, remains from thefe a white faline matter, of a particular tafte, not ungrateful, nor nitrous, but perfectly mild.

Hence we fee that *nitre* is changed into a new falt by detonation with antimony.

This falt is gently aperitive, and, in denfe, inflammatory blood, excellently refolves without violence. It fuccefsfully promotes perfpiration, fweat, and urine; hence it cools, and becomes greatly ferviceable in the fmall pox, meafles, pleurify, and peripneumony. We fee how erroneous has been the opinion of this water being noxious, and how valuable a medicine that opinion had led people for a long time to throw away.

NITRUM *calcarium*, in natural hiftory, a name given by Dr. Lifter to a peculiar fpecies of neutral falt, which he firft publickly defcribed in his book on the medicinal waters of England. He very improperly calls it *nitre*; becaufe it has none of the properties or qualities of *nitre*, but only a fort of general refemblance in its external form. He obferves that this falt, tho' very little known, was abundantly the moft copious of all the forts afforded by the mineral waters in general; and fays its cryftals were long and flender, and confifted of four fides, and were terminated by a point compofed of two triangular planes. He adds, that this falt doubtlefs had its origin from a mixture of the acid of fulphur, and a calcarious earth of an alkaline nature.

This falt is found in almoft all the mineral waters of Germany, and is very juftly obferved by Hoffman to be of the nature of Glauber's falt: that it is not *nitre* is evident from this, that it is not inflammable, nor will yield aqua fortis by diftillation. It feems, indeed, true Glauber's falt, compofed of the acid of vitriol, or fulphur, for this is in both the fame, and of that alkaline earth which is the bafis of fea falt: this is its origin, in the veffels of the chemift, as well as in the bowels of the earth, and probably the figure of the cryftals of that obferved by Dr. Lifter, was the fame in the point, as well as in the body, both being quadrilateral columns terminated by pyramids compofed of a number of triangular planes. *Hoffman* Opera, T. 5. p. 139.

This number in Glauber's falt is four, though Dr. Lifter obferved only two in the falt he examined; but it is frequently feen in the factitious, or common Glauber's falt, which naturally has four planes in the pyramid, that two of them are fo fmall, as fcarce to appear more than flat fparks at the verge of the point; in almoft all the cryftals, one of the four is thus fmall, fo that they feem to confift only of three, while the whole four are truly there. The fame is the cafe frequently in the common rock cryftal, whofe pyramid ought to confift of fix planes, and, in truth, always does fo, but one or more of them are frequently fo fmall, that a hafty obferver would fay it confifted only of four or of five planes.

If this may be allowed to be the cafe, in regard to Dr. Lifter's obfervation of his cryftals, there feems no doubt but that his *nitrum calcarium* is true and genuine Glauber's falt, as much as that of the chemift's laboratory; and, according to his own juft obfervation, it is compofed of the very fame principles with that chemical falt. The mineral waters of Egra abound with this falt, which Hoffman alfo has called, for that reafon, *fal Egranum*, when feparated from them by evaporation; but none contains fo great a proportion of it as the Sedelitz waters, a pint of which, on evaporation, leaves two drams of it.

The medicinal waters in the neighbourhood of Paris contain it alfo in a very confiderable quantity, though lefs than this. It is the opinion of Hoffman, that when any water before impregnated with a vitriolic acid, in its current under ground, paffes over this calcarious earth, it as readily joins a part of it with it, as the vitriolic acid does with the fea falt, or its bafis, in the making the common Glauber's falt, and thence produces a bitter purging falt, of the fame nature with that; and, indeed, if the acid of fulphur be mixed with any alkaline fubftance, a bitter neutral falt is produced, fomewhat analogous to this, and to the Glauber's falt.

NITRUM *nitratum*, in chemiftry, the name of a preparation of *nitre*, made by adding a fufficient quantity of fpirit of *nitre* to a lixivium of pure *nitre*, and afterwards evaporating it to a pellicle, and fetting it by to fhoot. The cryftals formed by this liquor are perfectly nitrous in their figure, but they will be of an acid tafte.

We fee, by this, that it is poffible to alter a falt, and to reduce it into the appearance of a different body, by means of fubftances before feparated from itfelf; and, in this cafe, the alteration is made, in almoft any degree, at pleafure; the falt produced being more or lefs acid, as more or lefs of the acid fpirit is ufed: but it is to be obferved that the more acid there is ufed, the more difficultly the falt dries, and the more difficultly it is kept dry, it being always fubject to run in the air. This preparation of *nitre* is a good medicine in burning fevers. *Boerhaave's* Chem. Part 2. p. 176.

NITRUM *purificatum*, *purified nitre*, is thus prepared: take *nitre*, or common falt-petre, one pound; pure water three quarts and a pint; fet them on the fire together, and diffolve the falt perfectly by boiling: then ftrain the hot lixivium through a double flannel, and fet it over the fire again in an earthern veffel. Evaporate it gently, till on taking out a little of the liquor in a fpoon as it cools, there are feen threads as it were fhooting in it; in this ftate the falt is ready to concrete. Set it in a cool place, putting clean fticks acrofs the veffel, and the falt will form itfelf into extremely pure and beautiful cryftals on the fide of the veffel, but principally on the fticks. Thefe dried in a colander are fit for ufe.

This is the beft of all the preparations of *nitre*, for medicinal ufe, in its native form. It diffolves immediately on entering the body, where it wonderfully cools, and thins the blood, giving it a fine florid colour. In all inflammatory difeafes attended with condenfations of the blood, this falt proves excellently cooling and attenuating. It is given from four or five grains to ten, twelve, or fifteen at a dofe. Some give more at a time, but it is more advifeable to have the dofes fmaller, and oftener repeated. It is alfo good in the fmall-pox, and fuppreffions of urine. It is alfo faid to be given by many in hæmorrhages with fuccefs. If there be any cafe in which caution is required, it is in a confumption where the lungs are ulcerated.

NITRUM *vegetans*, a name given by the chemifts to a preparation of *nitre*, which very readily fhoots out into beautiful cryftallizations. If, in the making Glauber's fpirit of *nitre*, there are ufed four parts of *nitre*, and one of oil of vitriol, and the fpirit be entirely driven off, the white falt remaining dry in the retort, on being expofed to the open air, will foon he covered with a thick and long down, as if it grew; but if this falt be diffolved in water, and there ftrained, and evaporated to a drynefs, in a cylindrical glafs, and kept expofed to the open air, its upper furface will often appear covered with beautiful branching little plants, all which will diffolve away upon the application of heat, and leave the furface even; but upon expofing the veffel again to the open air, in a quiet place, they will grow again as before, thus feveral times exhibiting the refufcitation of plants, as it were, from their own afhes.

Some chemifts have formed feveral fables upon fome fuch bafis as this; and, very probably, the whole fecret of their operations was no more than a concealed fraud of this kind, this having nothing to do with vegetation.

NITRUM *vitriolatum*, a preparation of *nitre* made as follows: Diffolve the mafs left in the retort after diftillation of a fpirit of *nitre*, in about eight times its weight of water; filtrate the folution, and, when perfectly clear, evaporate the liquor to fuch a ftandard, that the falt will no longer be fuftained in it; then fet it in a cool place, and collect the falt as it fhoots, laying it in an earthen colander to dry. This is of much the fame virtues with *tartarum vitriolatum*, and is frequently fold under its name. See TARTARUM *vitriolatum*.

NIVALIS *avis*, the *fnow-bird*, a name given by authors to a bird common in Poland in the fevereft months of the winter, and at no other time. The country people call it *fniegu ka*, which fignifies *fnow-bird* alfo: it is obferved to come with the fnows, and go away again with them. The country people ufe to prefage the mildnefs, or the feverity of the fucceeding winter from their flights in greater or in fmaller numbers, or earlier, or later, in the feafon.

NIURI, in botany, the name of a genus of plants, called by Linnæus *phyllanthus*. Hort. Mal. 10. 27. See the article PHYLLANTHUS.

NOAH's *ark fhell*, in natural hiftory, the name of a kind of fea fhell, which authors were always puzzled about referring to any genus, till a late French author has referred it to a new genus he has made under the title *cordiformis*, taking in the bucardia, and triangular heart-fhells. The cabinets of the curious afford us three fpecies of this fhell; the common kind, a yellow and white kind, with broad irregular lines, and a variegated kind. Hift. Nat. Eclair. p. 333.

Mathiolus and Rondeletius have called the *noah's ark fhell*, *rhomboides*, and *mufculus ftriatus*; and Lifter, who has followed thefe authors, has placed it among the mufcles. Rumphius has placed it among the pectens, and fome have made it a fpecies of oyfter. The impropriety of its arrangement under any of thefe genera is very obvious from the characters of each. It is indeed of a fomewhat different figure from the generality of heart-fhells, as it is from all the other fhells in the world, but it agrees with them in its general character, for it is deeply ftriated, as they all are; and it is of a figure, in fome meafure, refembling that of a heart, though running out into an irregular length at the point.

We have another fhell of this genus which no one ever doubted to belong to it, which yet is of an oblong figure, and fo much refembles the *Noah's ark*, as to plainly fhew they ought both to be reckoned fpecies of the fame genus. This is the oblong bucardium, or ox heart fhell, commonly called the *baftard Noah's ark*.

NOCERIANA *terra*, *earth of Nocera*, in the materia medica, a white

white earth used in medicine in Germany, Italy, and some other parts of the world, but not known in the English shops. It is now dug principally about Macerata, a city in the marquisate of Ancona, in the pope's territories, and is in great esteem in malignant fevers, and against the bites of venomous animals.

It is a dense earth, of a greyish white, very hard, and of an insipid taste, and does not effervesce with acid menstruums. *Hill*'s Hist. of Foss. p. 3.

NOCTAMBULATIO, *walking in the sleep*. This is a very remarkable distemperature of the imagination, and, in different persons, differs greatly in degree. Those who are but moderately affected with it, only repeat their actions of the day, and getting out of the bed, go quietly to the places they frequent at other times; but those who are afflicted with it in the most violent degree, go up to dangerous places, and do things that would terrify them to think of, when awake: these are by some called lunatic *night-walkers*, because fits are observed to return with most frequency, and violence, at the changes of the moon.

Causes of it. The only material cause that can be assigned in this case, is a plethora, or over-fullness of blood, but this is influenced by an immaterial one, that is, by the fancy, which is busily employed in dreams about particular objects.

Method of cure. The primæ viæ are first to be cleared of all their foulnesses by a strong purge; after this it is proper to bleed in the foot, taking away eight or ten ounces; then powders composed of nitre, cinnabar, and crab's eyes, should be taken three or four times a day, and particular regard should be had to the changes of the moon. It will be proper to set a vessel of water by the bed-side, in such a manner that the person will naturally step into it on getting out, and be awaked by that means; and if these things fail, a person should be set up to watch him, and beat him, every time it happens. *Junker*'s Consp. Med. p. 698.

NOCTIBO, in zoology, the name given by the Portuguese to a small Brasilian bird, a species of the *goat-sucker*, or *churn-owl*, more known among naturalists by its Brasilian name *ibijau*. *Marggr.* Hist. Brasil. See the article IBIJAU.

NOCTUA *aurita*, in zoology, a name by which some have called the smaller species of the *horn owl*, more usually distinguished by the name *otus*. *Ray*'s Ornithol. p. 63. See the article OTUS.

NOCTUA *canora*, in zoology, a name given by Nieremberg to a bird of the Spanish West-Indies, called by the natives *chicantli*, and sometimes kept by the Spaniards in cages. See CHICANTLI.

NOCTUA *minor*, in zoology, the name given by Mr. Ray to the *keutzlin*, or, as others call it, the *schaffilt*, a very beautiful little bird of the owl kind, and not exceeding the size of the common thrush. *Ray*'s Ornithol. p. 69. See SCHAFFILT.

NOCTUINI *oculi*, a name given by some to grey eyes, from their resembling those of the *noctua*, or *owl*.

NOCTUOLENT, among botanists, a name given to such plants as smell strongest in the night time. See DOG-*rose*

NODULUS, a word used in pharmacy for a knot tied in a rag, and including some medicinal ingredients to be suspended in any liquor. See NODULE, *Cycl.*

NOERA, a word used by some chemists for the head of an alembick, or the cover of a cucurbit, or any other vessel used in distillation *Castell.* Lex. in voc.

NOFESCH, in natural history, a word of Hebrew origin, used as the name of a precious stone. There has been much dispute among the commentators on the old testament, what stone it was. It seems derived from the root *fuch*, which signifies the ruby, or carbuncle, and, as a derivative of that word, it must be supposed to express a red stone, not one of any other colour As the ruby is signified by *fuch*, this cannot mean the same stone, and therefore probably meant the garnet, they having no other name, that we known of, for that stone, and it being very like the ruby.

NOCHETZLINOPALLI, or NOCHEZNOPATLI, in botany, a name by which some authors have called the *opuntia*, on which the cochineal insect loves to feed. *Jonf.* Dend. p. 56. See OPUNTIA.

NOISETIER, in botany, the name by which the French call the several species of hazel, and filbert-trees. See HAZEL.

NOLA, in botany, a name used by some authors for the *anemone*. *Ger.* Emac. Ind. 2.

NOME (*Cycl.*) — NOME, Νομη, in medical writers, is used for an eating, or corroding ulcer, and is much the same with *phagedæna*. See PHAGEDÆNA, *Cycl.*

The word is Greek νομη: it occurs in Galen. Some later writers, as Forestus, call it *ulcus obambulans*, and *obambulativum*. *Castellus.*

NOME, among the antient Egyptians, a division, or province, into which the whole kingdom was divided. The origin of the *nomes*, according to Diodorus Siculus, was this: the inhabitants being refractory, and much inclined to insurrections, in order to prevent these, the kings divided the whole country into different provinces, or *nomes*, and established the worship of some particular animal in each of them, prohibiting at the same time such animal to be eaten within the bounds where it was worshipped.

Hence, as every province was intoxicated with its own particular form, and object of worship; it entertained the highest contempt for that of its neighbours, and took a pleasure in profaning the animal, which among them had divine honours paid it. This religious opposition had the desired effect; for, all mutual confidence being thereby cut off, there were no more insurrections against the government. Mem. Acad. Inscrip. Vol. 13. p. 52.

NOME is also used for a kind of song, or hymn, in honour of the gods, said to have been invented by Terpander. For a further description of which, see Mem. Acad. Inscrip. Vol. 14. p. 342, seq.

NOMENCLATORES, (*Cycl.*) among the botanical authors, are those who have employed their labours about settling and adjusting the right names, synonyms, and etymologies of names, in regard to the whole vegetable world. *Linnæi* Fund. Bot. p. 2.

NOMOPHYLACES, Νομοφυλακες, among the Athenians, magistrates who were to see the laws executed, being not unlike to our sheriffs. They had the execution of criminals committed to their care, as also the charge of such as were confined prisoners. They had also power to seize thieves, kidnappers, and highwaymen, upon suspicion; and, if they confessed the fact, to put them to death; if not, they were obliged to prosecute them in a judicial way. *Potter*, Archæol. Græc. T. 1. p. 78.

NOMOPHYLACES were likewise officers belonging to the Olympic games, whose business it was to instruct those who were to contend, in all the laws of the games. See HELLENODICÆ.

NOMOTHETÆ, Νομοθεται, among the Athenians, were a thousand in number, and chosen by lot out of such as had been judges in the court *Heliæa*. Their office was not (as their name seems to imply) to enact new laws by their own authority, for that could not be done without the approbation of the senate, and the people's ratification; but to inspect the old, and, if they found any of them useless, or prejudicial, as the state of affairs then stood, or contradictory to others, they caused them to be abrogated by an act of the people. Beside this, they were to take care that no man should plough, or dig deep ditches within the Pelasgian wall; to apprehend the offenders, and send them to the archon. *Potter*, Archæol. Græc. l. 1. c. 13. T. 1. p. 79.

NON (*Cycl*) — NON *assumpsit*, in law, a plea in personal actions, whereby a man denies any promise made, &c.

NON *distringendo*, a writ not to distrain, used in divers cases. *Blount*, *Cowel.*

NON *implacitando aliquem de libero tenemento sine brevi*, a writ to prohibit bailiffs, &c. from distraining any man touching his freedom, without the king's writ. Reg. Orig. 171. *Blount*, *Cowel.*

NON *intromittendo quando breve præcipe in capite subdole impetratur*, a writ directed to the justices of the bench, or in eyre, commanding them not to give one that had, under colour of intitling the king to land, &c. as holding of him *in capite*, deceitfully obtained the writ called *præcipe in capite*, any benefit thereof, but to put him to this writ of right. Reg. Orig. 4. This writ having dependance on the *court of wards*, since taken away, is now disused. *Blount*, *Cowel.*

NON *merchandizando victualia*, a writ to justices of assize to enquire whether the magistrates of such a town do sell victuals in gross, or by retail, during the time of their being in office, which is contrary to an antient statute, and to punish them if they do. Reg. Orig. 184. *Blount*, *Cowel.*

NON-*spissum*, in the antient music. See APYCNON.

NON-*such clay*, a particular sort of earth, which, mixed with another clay brought from Worcestershire, makes a composition very useful for the making the melting-pots used in the green glass making. *Neri*'s Art of Glass, p. 246.

NONUPLA, in the Italian music, denotes a quick time, peculiar to jigs. This species of time is otherwise called *the measure of nine times*, which requires two falls of the hand, and one rise. There are three sorts of *nonupla*. 1. *Nonupla di semi-minime*, or *dupla sesqui quarta*, thus marked $\frac{9}{4}$, where nine crochets are to be in the bar, of which four make a semibreve in common time, i. e. in the down stroke, six, and but three up; it is usually beat *adagio*. 2. *Nonupla di crome*, or *sesqui ottava*, marked thus $\frac{9}{8}$, wherein nine quavers make a bar, instead of eight in common time, i. e. six down, and three up: 'tis beat *presto*. 3. *Nonupla di semi-crome*, or *super setti partiente nona*, thus distinguished $\frac{9}{16}$, in which nine semi-quavers are contained in a bar, whereof sixteen are required in common time, six down, and three up: 'tis ordinarily beat *prestissimo*. See ADAGIO, PRESTO, and PRESTISSIMO.

Beside these, there are two other species of *nonupla*, for which see TRIPLE, *Cycl.*

NOOZE, a name given by sportsmen to a sort of horse-hair springe made to take woodcocks, and very successful, when the proper precautions are taken. The *nooze* is made of several long and strong hairs twisted together, with a running *nooze* at

at one end, and a large knot at the other, which is to be paſſed through the ſlit of a cleft ſtick, to prevent the *nooze* from being pulled away when the bird is caught in it.

The ſportſman, when he knows his buſineſs, does not ſtay to watch theſe ſnares, but ſets them in the morning, and returns again to them at four in the afternoon, when he ſeldom fails of meeting with a ſufficient number taken. The ſticks are to be about the bigneſs of a man's little finger, and are to be made ſharp at one end, that they may fix the better in the ground: to each of theſe is to be fixed one *nooze*. The ſportſman is to take out with him ſeveral dozens of theſe bundled up together, and going into the coppice woods where there lie many leaves upon the ground, he is to ſearch among theſe for the marks of woodcocks frequenting the place; if there come any there, it will be ſoon found out by the leaves, which are ſpread about from ſide to ſide by thoſe birds, in ſearching under them for worms Their dung alſo, which is of a dark grey colour, being found about the place, is a proof of their frequenting it.

When the place is thus pitched upon, the ſportſman is to take a large circle at ſome diſtance from it, on each ſide, in the way where the woodcocks are ſuppoſed to come to the place; he is here to plant a ſmall hedge row of furze, or other buſhes, of a conſiderable extent, and pretty thick, leaving gaps in it here and there. The woodcocks, in making up to their place of feeding, when they come to this hedge, will run along by the ſide of it, till they come to one of the gaps, and then go through, for they hate to take wing, and will run, at any time, a long way under a hedge, rather than fly over it. On this depends the ſucceſs of the ſport.

The *noozes* are to be fixed one in each of theſe gaps thro' which it is known the woodcocks will paſs; the ſtick to which it is faſtened is to be ſtuck firmly in the ground, and the *nooze* to be ſpread wide open on the ground, leaving only ſome dry leaves to ſupport it. The whole gap being occupied by this *nooze*, the woodcock, when he comes, cannot eaſily eſcape being taken by the legs in it, and when once caught he will lie till the ſportſman comes. While a ſportſman is walking about a wood in this view, it is very common for him to find ſpringes, or *noozes*, of horſe-hair, fixed at ſix inches high, in ſeveral places. This may be looked on as a proof that there are partridges in the wood, and theſe are the means uſed by the country people to take them. The woodcocks, though in the day they lie in woods, yet, in the night, they go out, and frequent rivers and brooks, and, in the froſty nights, ſuch ſprings as do not freeze are particularly reſorted to by them.

The ſportſman, when he has ſet his *noozes* in the woods for the day-time, ſhould retire to the watery places near them, and ſearch for the marks of theſe birds coming to them by their dung, and other tokens. As ſoon as a place is found which they frequent, there muſt be a ſmall hedge row built there alſo in the ſame manner as in the woods; and in the gaps, which are to be made at the diſtance of about ſix foot one from another, there are to be placed either the ſame ſort of *noozes* as thoſe in the woods, or the ſpringes made with hazel boughs, and the horſe-hair tied to a packthread. In either caſe, there is no doubt of ſucceſs, for the birds which have once frequented a place, will come to it every night, as long as they remain any where near it; but particularly, if there be any ſpring near a wood, the water not freezing when other waters are iced over, will be ſure to bring the woodcocks together at it, and *noozes* planted properly about this place, will ſeldom fail of ſucceſs. If they have been left a night or two without ſucceſs, the ſportſman is not to deſpair; for though there ſhould happen to be no woodcocks there when they are firſt ſet, theſe birds change place ſo often, that it need not be doubted but ſo proper a rendezvous will be ſoon reſorted to by them.

NOPE, in zoology, an Engliſh name uſed by ſome for the *bull-finch*. See BULL-*finch*.

NORA, a word uſed by ſome of the chemical writers for *lime*, by others for *nitre*, and by others for all ſalts in general, as the word *ſal*.

NORTH (*Cycl.*) — NORTH-*weſt paſſage*. A *north-weſt paſſage* by Hudſon's bay, into the pacific ocean has been more than once attempted of late years, but, hitherto, without ſucceſs. Some greatly doubt of the practicableneſs of ſuch an enterprize, and think the obſervations made by the Ruſſians give us ſmall hopes. But, as they have not yet publiſhed the particulars of their diſcoveries, little can be ſaid about them. Some general things may be ſeen in the Phil. Tranſ. N° 482. Sect. 14. It appears from thence, that the Ruſſians have paſſed between the land of Nova Zembla, and the coaſt of Aſia, and, as the Dutch did formerly diſcover the northern coaſts of Nova Zembla, we may now be well aſſured, that that country is really an iſland.

NOSE (*Cycl.*) — *Bleeding at the* NOSE. An hæmorrhage of the *noſe* is an uſual remedy of nature to relieve herſelf, in caſes of a plethora, and a difficult circulation. It is often wholly ſalutary, and comes on, in ſuch caſes, leiſurely; proceeds without violence, and ſtops at a proper time. But it is ſometimes to be looked on as a diſeaſe coming on haſtily, continuing with violence, and bringing on very bad ſymptoms. Bleedings at the *noſe*, in acute diſeaſes, are ſometimes critical, happening on the days of the criſes, and theſe are uſually copious: ſometimes they are merely ſymptomatic, happening at indeterminate and uncertain times; ſuch are the bleedings from this part in the ſmall-pox, and in petechial fevers: the firſt are ſalutary, theſe rather of bad conſequence.

The lighter hæmorrhages of the *noſe* are often preceded by no ſymptoms, but break out placidly, and go off in the ſame manner. The more violent ones are uſually preceded by a congeſtion of blood about the head, a redneſs of the cheeks, an inflation of the face, a turgeſcence of the veſſels of the temples, and the neck, a noiſe and ringing in the ears, a heavineſs of the eyes, and often a ſparkling of light in them; a vertiginous diſorder of the head, a binding of the bowels, a thinneſs and diminution of quantity of urine, tenſions in the hypochondria, a ſuppreſſion of cuſtomary ſweats, and a coldneſs of the lower parts.

Perſons ſubject to it. Theſe are young people, principally thoſe between the age of fourteen, and one and twenty; and thoſe of plethoric habits. Women are leſs ſubject to them than men. Scorbutic habits uſually throw people into bleedings at the *noſe*; which is not wonderful, ſince the ſcurvy principally owes its riſe to a plethora. Theſe bleedings are brought on by violent emotions either of the mind, or body, by blows on the part, by a too copious uſe of wine, or hot foods, and ſpicey things; by great heat of the weather, or of the room where a perſon remains ſome time; and ſometimes by much lighter cauſes, as barely the waſhing the face, or bending the head too much toward the earth.

Prognoſtics. It is commonly known, that moderate bleedings at the *noſe* relieve people in heavineſſes of the head, and pains and numbneſs in the limbs, and occaſion a more chearful turn of mind. But when this diſcharge is injudiciouſly treated, or raſhly ſtopped by aſtringents, there often ſucceed violent fullneſs and inflations of the veſſels of the head, and dangerous inflammations of the eyes, and other parts. Too frequent bleedings at the *noſe* in young perſons ſometimes preſage conſumptions, for the congeſtions which occaſioned them turning upon the breaſt as the perſon grows up, occaſion ſpitting of blood, and finally a phthiſis. A critical bleeding at the *noſe*, if ſufficient in quantity, often happily carries off a fever. In petechial fevers, ſymptomatic hæmorrhages at the *noſe* are very bad ſymptoms; and, in the ſmall-pox dangerous, though leſs fatal than in this diſeaſe. An habitual hæmorrhage from the *noſe* in grown perſons, is often a ſymptom of ſome diſtemperature in the abdominal viſcera; and, in old people, they often preſage apoplexies, and vertigoes; for when there is a conſtant congeſtion of blood about the head, and this accuſtomed diſcharge is any way impeded, it is often ſeen that theſe diſeaſes are the effect.

Method of treatment. In all bleeding at the *noſe*, if the blood flows moderately, if it ſhews by its fluid ſtate, that it reſults from a plethora; if it is not too great for the age and ſtate of the patient, and if it be habitual, and uſe to be attended with good conſequences, nothing is to be done to impede or ſtop it. But if they be violent, and return often, or if the quantity of blood diſcharged be too great for the ſtrength of the patient to bear, and they are uſually attended with bad conſequences, then the aſſiſtance of medicine is neceſſary. Nitre, mother of pearl, cinnabar are to be given in powder, and decoctions of daiſy roots, comfrey, and poppy flowers in large draughts, with jellies of hartſhorn and ivory; and, if neceſſary, ſome gentle opiate, and a proper diet muſt be preſcribed; the abſtaining from ſpirituous liquors, and high-ſeaſoned foods being abſolutely neceſſary, and the keeping out of great heats, and avoiding violent paſſions, being equally neceſſary. Bleeding and purging are proper after the fit is over, to prevent a return; and to theſe may be added warm baths for the feet, and the common diaphoretics. *Junck.* Conſp. Med. p. 20.

Fracture of the NOSE. In the *noſe* both bone and cartilage are ſubject to fractures, which happen ſometimes on either ſide, and ſometimes in the middle from blows or falls; if either of the bones in the front of the *noſe* are fractured, it produces a flatneſs in the *noſe*, and the air meets with obſtructions in its paſſage through the noſtrils; and if the bone, on either ſide, is fractured, the part becomes hollow. When the cartilage is diſturbed, the *noſe* inclines too much on one ſide. Theſe fractures ſometimes happen without a wound, but more uſually they are attended with a wound of the common integuments. If the injury of the *noſe* is very great, the fracture can never be ſo perfectly cured, but that ſome deformity will remain. The vicinity of this part to the brain alſo, which is frequently injured at the ſame time, renders caſes of this kind often dangerous. A caries alſo, or an ozæna, or polypus, are no uncommon attendants on this diſorder. In order to reſtore the bones of the *noſe* to their proper ſituation, the patient is to be placed in a ſeat oppoſite to the light, and his head held back by an aſſiſtant. The ſurgeon is to raiſe the depreſſed parts with a ſpatula, a probe, or a quill, applying externally the thumb of one hand, and the fore finger of the other. If the bones of the *noſe* are fractured on both ſides,

they are to be raifed on each in this manner, and the cavity of the noftrils is to be filled up with long doffils, to prevent the bones from collapfing; covering the part alfo for this end with fome plaifter, and applying firft the dreffings common in recent wounds. If the bone is fractured into feveral fplinters, they are to be reduced into their proper places by the fingers; but if a fplinter is fo entirely feparated from the bone, that it will not eafily unite with it again, it is to be taken out with the forceps. The bones will unite, when properly replaced, in about fourteen days, if no caries, or abfcefs intervene. If the bone fhould require a ftronger fupport than what has been hitherto mentioned, one may be formed out of ftrong paper, either fingle, or double, and adapted to each fide of the *nofe*, and fupported by bolfters, and the whole muft be kept in its place by a four headed bandage not tied too tight. *Heifter*, Surg. p. 117.

Luxated Nose. It fometimes happens, though not often, that the bones of the *nofe* are feparated from each other, or diftorted out of their natural places, without a fracture. When this cafe happens, the patient is to be fpeedily placed in a high chair, and an affiftant muft ftand behind, and hold his head firm in a proper pofture: the furgeon is then to introduce with one hand a thick probe, a goofe quill, or a fmall ftick fhaped for that purpofe up the noftril internally, by which means the depreffed parts of the *nofe* may be thruft out into their places: in the mean time he is to apply his other hand externally, to guide, and direct the parts which are thus moved from within. This being done, and the bones properly replaced, there is fcarce any thing elfe to be done, but to let a piece of fticking plaifter lie upon the *nofe* for fome time. *Heifter*, Surg. p. 151.

Wounds of the Nose. Wounds of the *nofe* are generally cured by the dry future; but, where the wound divides the cartilage, and penetrates fo deep that the lips of it cannot be kept in contact by the application of fticking plaifters, the true future muft be made through the fkin, on each fide of the wound; and Bleyny affirms that when a part of the *nofe* has been actually cut off, and feparated from the reft, it has been afterwards united, by means of futures. When the nafal bones have been fractured, it is ufual to place fmall tubes of lead, or filver, under them for fome time, left the paffage of the *nofe* fhould be ftopped up by the fhooting of new flefh. Externally fome vulnerary balfam, or glutinous powder, is to be ufed, and covered with fticking plaifters, which muft be kept on by the four-headed bandage. *Heifter*, p. 81.

Nose-*band*, in the manege, called in French *muferolle*, is that part of the head-ftall of a bridle that comes over a horfe's nofe

NOSTOCH, the name of a vegetable fubftance which feems to differ from moft of the other bodies of that kind, in feveral particulars.

It is a fubftance of an irregular figure, of a greenifh brown colour, and fomewhat tranfparent. It trembles at the touch, in the manner of a jelly, but it does not melt when held in the hand. It has therefore fomewhat of the character of a vegetable leaf, but it has neither veins nor fibres.

It is found in all forts of foils, but moft frequently in fandy ones, fometimes on the gravel of garden walks, and moft ufually makes its appearance after rain. It is found only in the fummer months, and retains its humidity and perfect figure fo long as it is a moift feafon, but immediately dries up, and withers away, on the fun, or winds affecting it.

Many people have fuppofed this not to be a plant; it appears all on a fudden, and, as it were, by a fort of miracle, either from the earth or clouds, and fome have called it *flower of earth*; others *flower of heaven*; and the obfcurity of its origin has occafioned its being held in great efteem among the chemifts, who fuppofe that it contains an univerfal fpirit capable of converting other metals into gold. Memoirs Acad. Par 1722.

Mr. Magnol, and Mr. Tournefort, were the firft authors who afferted its true origin, and ranged it among the plants. Its nature, however, was never perfectly difcovered till Mr. Reaumur took it under confideration. This accurate obferver foon found that it was a leaf which naturally imbibed water in a very particular manner; that when it had enough of this liquor in it, it then appeared in its natural flourifhing ftate; and when it loft this again, it became thin, and wrinkled, and was not to be known for the fame fubftance, or, indeed, fcarce to be feen at all. Hence appears the reafon of its fuppofed fudden production, and decay. If it has, ever fo long, lain in the walks of a garden in its empty wrinkled ftate, it is never taken notice of; but, on a fhower of rain, it imbibes the water, and immediately fwells out into this jelly-like ftate, and, on the fun's evaporating that moifture, it falls into its undiftinguifhable ftate again; and thefe changes may affect the fame plant alternately for many days together.

Mr. Geoffroy imagined that he had found roots to the *noftoch*; but Mr. Reaumur pofitively afferts that it has none. He obferved, indeed, at certain times, on the furface of fome fpecimens of this, a vaft number of round tubercles of different fizes, which appeared to be the feeds of the plant: thefe be regularly fowed in earthen pots of mould, and thefe produced young plants like the parent *noftoch*, but even thefe were never difcovered to have any appearance of roots; and, to try farther whether they had any, Mr. Reaumur turned all the plants bottom upwards, and they received no harm from it, but grew juft as vigoroufly as before.

If the *noftoch* has truly no roots, as appears to be very evidently the cafe, it follows that it imbibes its nourifhment in the manner of the fea plants, which imbibe the water by which they are nourifhed at all their pores.

It fhould feem that there are two fpecies of this *noftoch*, the one only a plain flat leaf; the other curled, wrinkled, and varioufly undulated: and it is on this laft, that the fruits which produce the young plants are principally found. It may be, however, that the one of thefe may be the male, and the other the female of the fame fpecies, as in many larger plants; or poffibly the being in the ftate of fructification alone may make the difference.

NOSTRILS (*Cycl.*) — The *noftrils* are fometimes fubject to be preternaturally clofed; though this is a cafe that but rarely happens. It is fometimes owing to a carelefs treatment in the fmall pox, in the bad kinds of which the *noftrils* have been known to clofe, and adhere fo ftrongly to the upper lip, which is found turned back at the fame time, as to leave no poffibility of fhutting the mouth. In this unhappy cafe, the only relief is by the knife, feparating the lip from the nofe, and then opening a paffage through each of the *noftrils*. Thefe are to be kept open, either with tents, or leaden pipes, and the lip preffed downward into its natural pofition by a comprefs and bandage, and this continued till the wounds are ficcatrized. *Heifter*'s Surgery, p. 447.

Nostrils *of fifh*. See Nares *pifcium*.

NOSUS, a name by which fome of the barbarous writers of the middle ages have called *alabafter*: others alfo have called it *nifus*.

NOTHING (*Cycl.*) — Some modern mathematicians have diftinguifhed *nothing* into two kinds. They talk of *abfolute nothing*, and of *relative nothing*; but all this jargon is the refult of confufed notions, and ought to be banifhed out of geometry. See Infinitesimal.

NOTION (*Cycl.*) — This term, and the word *idea*, are often taken in the fame fenfe; but an ingenious author obferves, that we cannot ftrictly be faid to have an *idea* of an active being, or of an action, although we may be faid to have a *notion* of them. I have fome knowledge, or *notion*, of my mind, and its acts about *ideas*, inafmuch as I know, or underftand what is meant by thofe words. What I know, that I have fome *notion* of.

However, if the world will have it fo, the terms *idea* and *notion* may be ufed convertibly. But yet it conduces to clearnefs and propriety, that we diftinguifh things very different by different names. It is alfo to be remarked, that all relations including an act of the mind, we cannot fo properly be faid to have an *idea*, but rather a *notion* of the relations or habitudes between things; but, if in the modern way, the word *idea* is extended to fpirits, relations, and acts, this is, after all, an affair of verbal concern. *Berkeley*, Princip. of Hum. Knowl. Sect. 142. p. 160, 161. See Idea.

NOTONECTA, in natural hiftory, the name of a fpecies of water-infect, approaching to the nature of the cimex. It always fwims upon its back, and is very fwift in its motions. Its belly, which it fhews while in the water, is of a yellowifh white; its legs are long; when taken out of the water it hops. It is indeed a very beautiful, and very nimble little creature; and is common in the ponds of water in Hyde park, and in feveral other places about London. It has four wings, fix legs, and no antennæ; it is eight inches long, three broad, and two and a half thick. The body is black, and of a very particular form, being flattifh at the belly, and rifing to a ridge on the middle of the back; fo that when it fwims, which is almoft always on the back, its body refembles a boat in figure.

The belly is jointed, ftriated, and hairy, and has a large opening at the tail, out of which, when hurt, it thrufts forth fomething refembling a fting. The head and fhoulders are large, hard, and yellow, without any fpots; the eyes are large and red, and are of a fomewhat triangular form. The nofe is a long, green, hollow probofcis, terminating in a hard and fharp brown point; this, in its natural pofture, is kept under the belly, and reaches to the middle pair of legs. The outer pair of wings are of a pale flefh-colour, with fpots of a dead white; thefe are long, narrow, and fomewhat tranfparent: they terminate in a roundifh point, and perfectly cover the whole body. The triangular piece which ftands between the top of the wings, is hard and perfectly black; the inner wings are broader and fhorter than the outer ones; they are thin, and perfectly tranfparent, and are of a pale pearl colour. The legs are green and hairy; the foremoft pair are fhorteft; the middle ones longer than thefe; but the hinder pair are greatly longer than all the reft, fo that they ferve as oars, and are tufted with hair at the end to that purpofe. This creature moftly lives in the water, where it preys on fmall infects, killing them, and fucking their juices with its probofcis, in the manner of the water fcorpion, and many other aquatic infects; and it feizes its prey violently, and darts with incredible fwiftnefs to a confiderable diftance after it.

Though it generally lives in the water, it sometimes, however crawls out in good weather, and drying its wings by expanding them in the sun, takes flight, and becomes an inhabitant of the air not to be known for the same creature, unless to those who had accurately observed it before; when tired of flying, or in danger of an enemy, it immediately plunges into the water. If taken into the hand, it stings, and gives an intolerable pain, but this goes off in a very few minutes. This is the species most frequently met with, but it is not the only *notonecta* we have, three or four other kinds, different in size, and colour, being found not unfrequently in large waters.

NOVACULA *piscis*, the *razor-fish*, in zoology, the name of a sea-fish caught in the Mediterranean, and some other seas, and much esteemed at the tables of the great.

It is of a very singular shape, having a large and flatted head with no snout, or nose; but its mouth, which is very small, is no more than a simple gap, or slit, in the lower part of the head; there are four long teeth in the fore-part of it, and all the rest is furnished with very small, but very sharp ones The eyes are small, and situated in the upper part of the head. It has two large fins at the gills, and two small ones on the belly. Its back is furnished with one long fin, not very high, but reaching from the beginning of the back to the tail The anus is placed nearer the head than the tail; and, from this to the tail, there is another long fin: its tail is large and broad. It is altogether of a flatted form. and is covered with large scales of very beautiful colours; the head and gills have several streaks of a fine blue; the belly-fins, and the tail, are of a cancellated work of green and yellow; the back fin is red spotted with black; and the body of the fish of a fine yellowish red.

It is a small fish, seldom exceeding three or four inches in length, and, in its flat shape, somewhat resembles the faber. It keeps about the shores, particularly such as are stony, and seems never to go into deep water; and is caught on the shores of Majorca Minorca, the island of Malta, and elsewhere, and lives nn small fish. *Salvian*, de Aquat.

NOVACULARUM *lapis*, in natural history, the name given by De Laet to a stone which he describes from Ximenes, who has it under the American name *iztli*.

It is the stone out of which the natives of America made their weapons of war, and tools for other uses of life, before they knew the use of iron.

There are three species of this stone, the one blue, the other white, and the other black; they are all capable of a very high polish, and, when set in gold, or silver, are very highly esteemed by the natives: they reflect the images of things, in the manner of all other highly polished bodies, and the two first are considerably transparent.

There are several quarries of these stones in the neighbourhood of Mexico, whence the Indians used to get them; they naturally split, in the getting out, into angular, and edged figures, and these they afterwards fashioned to the purposes they wanted them for, and polished with the powder of a harder stone.

They still make knives of them, in a very expeditious, and very remarkable manner. They hold the mass of stone between their feet, and, with an instrument prepared on purpose, they cut off pieces of four or five inches long, and about one inch broad, rising to a prominence on each side in the middle, and growing very thin toward the edges: it is wonderful to see with what expedition they finish this odd workmanship. The knives, when made, are sharper than any other instrument in the world; but they are very tender, easily broken, and more easily battered, and notched at the edges. They make also longer weapons of the same shape out of this stone, which they fix into wooden handles, with a sort of gum, and these serve them as swords. They are very terrible weapons for one blow, but they seldom hold together so as to bear a second. They make alsc the heads of their arrows of them, and when these were first found by our travellers they were not supposed to be of human workmanship, but to have fallen from heaven in thunder, and were called by many authors *ceraunia*. *Ximenes* Hist. Ind. Occid. l. 10. c. 13. See Ceraunia.

NOVENSILES, among the Romans, heroes newly received into the number of the gods, or the gods of the provinces and kingdoms which the Romans had conquered, and to which they sacrificed under the name of *dii novensiles*. *Danet*. Dict. in voc.

NOUER *l' eguillette*, in the manege. See Yerk.

NOURISHMENT (*Cycl.*) — Nourishment *of plants*. The antients in general gave to the earth the power of producing plants and animals, and whatever else lives upon, or exists in it; and for this reason they gave it the general title of parent earth, and mother of all things. They supposed that into this common parent all returned again at last; and that after a time of dissolution in its bowels, they returned back again into the formation of more bodies of the same kind. Even those among them who asserted the doctrine of the four elements, yet allowed that the earth was the matter which constituted those bodies, and that the other three, that is, fire, air, and water, served only to convey, and distribute this, as there was occasion; and Thales is only misunderstood, when he is supposed to think differently from this general system of the antients.

But though the antients all gave earth the power of producing animals, and other bodies, the moderns have gone into an opinion that water is the origin of all. Lord acon was one of the first who argued on this principle: he says, that for the *nourishment* of plants water is almost all in all; and that the earth only serves to keep the stalk upright, and to defend the root from over-heat, and over-cold. since the time of this great author many have been yet more express in this opinion, and have asserted that water is the only principle of all natural things, supposing that by some secret process of nature water is transmuted into stones, plants, and other things. Phil. Trans N° 253. p. 193.

Helmont attempted to prove this doctrine by many experiments; and Mr. Boyle who followed him through the whole course of his experiments, seems to assent to his opinion, that water is transmuted by nature into wood and stone, though, in his usual way, he delivers his thoughts with great modesty, and candour. The two principal experiments they build their opinions upon, are, that of mint, and some other plants growing in water; and that of a tree being planted in a small quantity of earth, which being baked to a dryness, and weighed before the tree was set in it, and again baked, and weighed afterwards, will be found to have lost nothing of its own weight, though the tree has encreased to a very great degree, only from the water with which they have wetted this earth from time to time.

It might be objected to the last experiment, that it is not easy to bake earth to the same degrees of dryness twice over, so as to have any hopes of being exact in the weight; but allowing ever so great an exactness in that, the experiment brings no proof with it, unless they can prove that the water which was used in the wetting it was pure and homogeneous, and not charged with any terestrial matter; for, if it were, the plant may, after all, owe its encrease entirely to that earth alone, and the water may only serve, according to the doctrine of the antients, to convey and distribute this grand *nourishing* element, in a necessary and proper manner.

It is true that water often appears so clear and pellucid, that one would scarce suppose any portion of so opake a matter as earth could be contained in it; but we find by chemical experiments, that so opake a body as silver may be dissolved in aqua fortis, so as to give it no colour, nor render it in the least degree less pellucid than before Our water, however, is not so pure in any case, as is vulgarly imagined. The naked eye will often discover particles of earthy matter, though very small, floating in the very clearest we have: and experiment shews, that, when evapor ted, all water leaves behind it a large quantity of opake, earthy matter, which we could not see in it by the naked eye.

This remainder of evaporated water, generally consists of particles of two kinds: the one part are found to be earthy, and such as are fit for the *nourishment* of plants, and these seem so different among themselves, on a nice examination, that they seem fitted either for the *nourishment* of different plants, or for that of the different parts of the same plant; the other particles are of a sparry and crystalline nature, and seem calculated for the production of stones, &c. In some springs, we also meet with many other principles suspended, such as alum, vitriol, nitre, ochre, and other things, and often many of them in the same spring; the water, as it passes through the strata of stone, earth, &c. often washing off, and carrying away, in a state of solution with it, the particles of those bodies in considerably large quantities. These are carried suspended in the water to the mouths of the springs, but they are not so well suspended afterwards. Phil. Trans. N° 2, 3 p. 196.

Vegetable earth, or that kind of mould which is necessary for the *nourishment* of plants, is more light than spar and other minerals, and is both more readily dissolved, and more easily suspended in water than these. Hence the waters of all rivers contain a great quantity of this, though very little of the other particles, they being always found most plentifully in water near its source, and less and less so the farther it has run in the open air. River water contains also more of this terrestrial matter than rain water, as is proved by easy experiments, though that contains some: and it is evident from the whole, that earth is contained in all water, and, therefore, that all water whatever is capable of conveying it into the bodies of plants, and distributing it through their several parts, for their *nourishment* and encrease.

If the clearest water be put into a clean vial, and stopped so as to keep out dust, the earth in it will soon be discovered: the motion of the water, while in its natural state, keeps this earth in small particles, and, therefore, they are less discernible; but, on being set to rest in this manner, these particles get together, and form larger combinations, which become more visible, and finally so many of them will join together, that they will become apparent, in form of small clouds of opake matter floating in the water; and these will become larger and larger, as they have yet more and more fresh matter added to them.

If this earthy matter be of a vegetable nature, it will remain fufpended in the water by means of its lightnefs, and will by degrees acquire a green colour, and this will become every day more and more green, as it acquires more and more matter to it. This colour is not to be wondered at, fince we find how very great a fhare of it is deftined to appear of the fame colour in plants.

When the water fuftains a large quantity of mineral, or fparry matter, this forms its concretions in the fame manner as the vegetable; and being heavier than this light vegetable earth, it fubfides to the bottom, and fometimes not alone, but entangling its particles among thofe of the vegetable kind, it carries them down along with it. It is palpable from thefe, and from a great number of other the like obfervations, that water of whatever kind does fuftain in it the matter of earth, fuch as is neceffary for the encreafe and *nourifhment* of vegetables; and it appears very confonant to reafon, that, in paffing through the feveral fmall veffels of the plants into which it is received, it depofites, and leaves behind it, this earth arranged into a proper form This the ingenious Dr. Woodward has proved by the experiments of plants growing in glaffes of water; an accurate lift of each of which is given at large in the tranfaction referred to in this article.

NOVUS *auris mufculus*, in anatomy, a name given by Fabricius to the mufcle called by Albinus *laxator tympani*, and by others *externus auris*, and *exterior*.

NUAYHAS, the *ague tree*, a name given by the Indians to a fort of bamboe cane, the leaves of which falling into the water, are faid to impregnate it with fuch virtue that the bathing in it afterwards will cure the ague.

They ufe alfo a decoction of the leaves to diffolve coagulated blood, giving it internally, and, at the fame time, rubbing the bruifed part externally with it. It is faid that this plant bears its flowers only once in its life; that it lives fixty years before thefe appear, but that when they begin to fhew themfelves, it dies away in about a month afterwards, that is, as foon as it has ripened the feed.

There feems fomething of fiction in the account of many other particulars of this tree, in the hortus Malabaricus, but it feems certain that the length of the ftalks, or trunk, muft be very great; for, in the gallery of Leyden, there is preferved a cane of it of twenty-eight foot long, and another but little fhorter in the Afhmolæan mufæum at Oxford, which is more than eight inches in diameter; yet both thefe appear to be only parts of the whole trunk, they being nearly as large at one end as at the other.

NUBA, a word ufed by fome writers to exprefs a peculiar fort of manna, or honey-dew, of a rofe-colour. Some chemifts alfo ufe it as a name for *copper*.

NUBECULA, a name ufed by fome authors for the diftemperature in the eye called *albugo*, and *leucoma*, by moft writers, being fpots in the cornea of the eye. *Heifter*'s Surgery, p. 421. See Albugo.

NUBELOSA *linea*, a term ufed by the Latin writers on heraldry, to exprefs a fort of clouded line in certain coats of arms. Our heralds call it *nebule*, and the French *nuance*. It is figured fo as to reprefent clouds at the edge, and was given to the firft of the families who bear it, as a token of their fkill in aftronomy and navigation.

NUBES, in natural hiftory, a word ufed by the antients to exprefs that whitifh foulnefs which we frequently fee in the bottom of the fineft columns of cryftal; we exprefs this by the fame word *cloud*.

The columnar emeralds are fubject to the fame fort of foulnefs at their bottom, and this part was called the root of the emerald properly enough, as it was that end of the column where it grew to the ftone; but the word root of emerald has been fince applied to feveral very different fubftances of a green colour, and fome degree of tranfparence.

NUBIGENUM *æs*, a term ufed by fome hiftorians to fignify copper generated in the clouds, and falling from thence with rain, or in ftorms. They talk alfo of iron, and of ftones produced the fame way, and call them *ferrum nubigenum*, and *lapides nubigeni*

Many of the German hiftorians mention the falling of iron in duft, and in large pieces; and Avifenna tells us fuch things of Italy. Julius Scaliger fays that he had by him a piece of iron which came down in rain in Savoy; and Cardan tells us of twelve hundred ftones falling from heaven, one of which was of an hundred and twenty pound weight, and others thirty or forty pounds apiece; they were all, he fays, of the colour of iron. Dr. Lifter is for fuppofing them to be genuine pyritæ, which, he fays, is foluble into vapour, and thus raifed into the air may there concrete again into its own form, or that copper and iron may concrete from it. Phil. Tranf. N° 156. See *præternatural* Rains.

NUCIFRAGA, in zoology, a name given by many to the *coccothrauftes*, or *grofs beak*, from its breaking nuts, and the ftones of fruits. See Coccothraustes.

NUCULA *terreftris*, in botany, a name given by fome to the *bulbocaftanum*. See Bulbocastanum.

NUDIPEDALIA, among the antients, a feftival in which all were obliged to walk bare-footed.

This was done on account of fome public calamity, as the plague, famine, an intenfe drought, and the like.

It was likewife ufual for the Roman matrons, when any fupplication and vows were to be made to the goddefs Vefta, to walk in proceffion to her temple bare-footed. *Pitifc*. Lex. Ant. in voc.

NUFAR, in botany, the name of the *water-lilly*. This was the original name, and was firft ufed by the Arabians; from them the Greeks borrowed it, and varioufly changed it. The Arabians themfelves added the prefix *nil* to it, to exprefs one particular kind of *water-lilly* of Ægypt; this they called *nil nufar*, or, for a fofter way of fpeaking, *ninufar*, and *nenufar*.

The Greeks borrowed this word, and wrote it firft *ninufarium*, and afterwards, for fhortnefs, *nupharium*. The afterwriters tranfpofed the letters, and made out of it, *nilufar*, *linufar*, a word wholly unintelligible, but by their tracing it back to its original. See Nilufar.

NUHAR, a name ufed by fome chemical writers for *copper*.

NUMERAL (*Cycl.*) — Numeral *figures*. The antiquity of thefe in England has been fuppofed as high as the eleventh century, from an antient date found at Colchefter, at firft thought to exprefs 1090; the figure in the place of hundreds being taken for a cypher, by not attending to the infide ftrokes, which were pretty near defaced; but upon a more accurate view that miftake was difcovered, and the date found to be 1490. See Phil. Tranf N° 439 and 475.

NUMELLA, among the Romans, an engine of wood ufed in punifhing offenders, whofe necks and feet were made faft in it. *Pitifc*. Lex. Ant in voc.

Numella was likewife ufed to denote a rope or cord made of raw ox-hides to bind beafts with. *Pitifc*. in voc.

NUMENIA, Νεμηνια, or Νεομηνια, in antiquity, a feftival obferved at the beginning of every lunar month, in honour of all the gods, but efpecially Apollo, who was called Νεομηνιος, becaufe the fun is the author of all lights; for whatever diftinction of times and feafons may be taken from other planets, yet they are all owing to him, as the original and fountain of all thofe borrowed rays, which the reft have only by participation from him. For the ceremonies of this folemnity, fee *Potter*, Archæol. T. 1. p. 416.

NUMENIASTÆ, Νεμηνιασαι, among the antients, a defignation given to thofe who kept a feftival on every new moon. See the article Numenia.

NUMENIUS, in the Linnæan fyftem of zoology, the name of a diftinct genus of birds, of the order of the *fcolopaces*. The diftinguifhing characters of this genus are, that the feet have each four toes, and the beak is longer than the toes. *Linnæi* Syft. Nat. p. 47.

Numenius is alfo a name ufed by many authors for the curlew, a bird more ufually known by the name of *arquata*. See the article Arquata.

Numenius *Indicus*, the *Indian curlew*, the name given by Clufius to the *guara* of the Brafilians, a very beautiful large bird, of the nature of the curlew, but of the fize of the *platea* or fpoonbill. *Ray's* Ornithol. p. 219. See Guara.

NUMIDICA *avis*, in zoology, a name given by many to the common turkey.

NUMIDICUM *marmor*, in the natural hiftory of the antients, the name of a peculiar fpecies of marble, which was of no great beauty, but fingular in its remarkable hardnefs, and capable of a very elegant polifh.

It feems to have been one of the firft marbles the Romans brought into ufe in pavements. It is a very firm, hard and ftrong kind, of a clofe texture, and in colour of a pale afhcoloured blue. It is found in Italy, Spain, France and Germany, but no where fo plentifully as in the laft country. It is a very durable and ftrong kind; but its want of variety in colour, makes it but little efteemed. *Hill*'s Hift. of Foff. p. 465.

NUMMULARIUS, among the Romans, was ufed to fignify a *banker*, or perfon who deals in money.

It likewife denoted an affayer, or one who eftimated the goodnefs and value of money, as to its weight and finenefs of metal. *Pitifc*. Lex. Ant. in voc.

NUN (*Cycl.*) — Nun, in zoology, the common Englifh name for the *parus cæruleus*, or blue titmoufe, diftinguifhed from the common titmoufe by its fmallnefs, and by its having a blue head, furrounded by a white line. *Ray*'s Ornithol. p. 176. See Parus.

Nun is alfo the name of a peculiar fpecies of pigeon, called by Moore the *columba veftalis*. It is but a fmall pigeon, but fomething larger than the jacobine, and has a very particular plumage, from which it has taken its name, its head being as it were covered with a veil.

The body of this fpecies is all white, the head, tail, and fix of the flight feathers black, red or yellow; the eyes are pearlcoloured, and the hood white: this is a large tuft of feathers on the hinder part of the head, and the more numerous they are, the more the bird is efteemed.

This is a very beautiful fpecies of pigeon, and is very much efteemed. Some of its feathers, however, will vary fome-

times from their true colour. These birds are called foul feathered. But it is a mere accidental variety, the young of such being often as perfect and beautiful as of any others. *Moore's* Columbarium. p 47.

NUNCIATION, *nunciatio*, among the Romans, was particularly used to signify the report which the augur made concerning what he had seen.

This he did to the chief magistrate present, and the magistrate communicated the same to the people, and so dismissed the assembly, which was called *obnunciation*. *Pitisc.* in voc.

NUSIADAT, a name given by some of the chemical writers to sal armoniac.

NUSTAM, a word used by Paracelsus and his followers to express the cream of milk, or the pellicle which in some cases swims upon the surface of wine.

NUT, among botanists, a pericarpium of an extraordinary hardness. See the article PERICARPIUM.

NUT-*hatch*, in zoology, the English name of a bird, known among authors by that of *sitta*; and from its climbing trees in the manner of the wood-pecker, called by some, tho' improperly, *picus cinereus*, the grey wood-pecker. *Ray's* Ornithol. See SITTA.

NUT-*jobber*, in zoology, an English name for the *sitta*, more commonly known among us by the name of the *nut-hatch*. See the article SITTA.

NUTRITION (*Cycl*) — *Defect of* NUTRITION, or ATROPHY. This takes its origin from the infarctions of the glands of the mesentery, and evidently manifests itself in the patient by a successive decay and attenuation of the parts.

An *atrophy* differs from a hectic in this, that there is in it only an infarction of the mensenteric glands, whereas in the other case they are generally ulcerated: and in degree the difference also is manifest, all the symptoms being more violent in the hectic than in the simple *atrophy*.

Signs of it. An *atrophy* is known by a general languor both of body and mind; a depraved and unhealthy look of the face; a light and unsettled sleep; an uncertain appetite, sometimes voracious, sometimes nauseating all things, but usually most desirous of cold foods; a straitness of the breast, and an uneasiness after eating; great internal heat, and dryness of the tongue. The bowels are usually lubricous and moist, and throw out the food half undigested: in some cases, however, they are observed to be dry and costive. The urine often appears to be a chylous matter: the abdomen is tumid and hard in the first stages of the disease, but afterwards it becomes more flaccid, and then on feeling it there may be several nodes and lumps perceived. The body by degrees wastes away, and there is a continual feverishness and thirst, and that especially in the night-time: and these symptoms often increase to that violence, as plainly to resemble a hectic, and bring on an equal loss of strength and spirits.

Sometimes the *atrophy* arises from worms, and then the whole face is always pale; the nostrils are full of a mucous matter, and sometimes become excoriated: the appetite is voracious, and the patient feels an insufferable restlessness when hungry, which goes off, and they generally become inclined to sleep after a full meal. When this is the case in young subjects, the rickets and swellings about the joints usually succeed the other symptoms, and crookedness of the legs, gibbosity of the back, and various distortions of the spine follow it: these often put an end to the *atrophy*; but as they continue, and become lasting deformities, they are a very unhappy remedy.

Persons subject to atrophies. Children, while very young, are most of all subject to this disease, and often fall into it from improper food: the use of heavy and fæculent malt liquors, and of acids, which coagulate the milk, that usually makes a large part of their nutriment. The suppression of their sweats is another frequent cause of *atrophies*, especially when occasioned by large draughts of cold liquors when they are hot in the night, and sometimes by an improper use of astringents to stop those diarrhœas to which they are frequently subject. Youths more grown up are often thrown into an *atrophy* by eating voraciously of crude, thick, heavy and obstruent diet, or from the drinking spirituous liquors: sometimes from their having been injudiciously treated in fevers, and sometimes from their being violently infested with worms in their bowels. Men grown up usually fall into it after being debilitated by other illnesses, and by the remains of the causes of those illnesses being left in the body; and by nothing oftener are reduced to this distempered state than by inordinate hæmorrhages. Persons who are scrophulous, or have infarctions of the external glands, usually also are at one time or other afflicted with this infarction of the internal ones, and few escape it that labour under any other violent concretions of the internal parts.

Prognostics. A recent *atrophy* is not difficult of cure; and even the most inveterate one, tho' stubborn enough, is always much less dangerous and difficult of cure than an hectic. The more complicated this disease is, the more difficult it always is in the cure; and it is hence that grown persons are not so easily or so often cured as children, because with them it is usually complicated with many other disorders; and, in general, that *atrophy* which is brought on by hæmorrhages, or by ill-treated illnesses, is much more difficult of cure than that which arises from a wrong diet. And, finally, in *atrophies* arising from worms, when they are destroyed, the disease usually ceases.

Method of cure. The first thing to be done in this case is, to thoroughly absterge and cleanse the primæ viæ by gentle purges, among which nothing is so proper as calomel, assisted by syrup of rhubarb, or the like, and these purgatives are afterwards to be repeated at different intervals, during the course of the cure. After the first purges, resolvent and attenuating medicines are to be given; and finally, the preparations of steel, decoctions of arum and pimpernel root, with ground-ivy, are very beneficial, as is also the juice of ground-ivy given alone; and the resolvent salts, as tartar of vitriol, nitre, and the like, with some of the aperient tinctures of steel. *Junker's* Consp. Med. p. 112, 214.

NUX (*Cycl.*) — NUX, the *wallnut-tree*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the amentaceous or catkin kind, and is composed of a great number of leaves affixed to an axis, and disposed in a squammose manner: under each of these there is placed a large cluster of apices. These flowers, however, are barren, and the embryo fruit appear in other parts of the tree. These finally become a hard shell, covered by a soft or fleshy one, and easily dividing into two halves, having within it a kernel usually consisting of four lobes, divided by a sort of woody septa.

The species of *wall-nut* enumerated by Mr. Tournefort, are these: 1. The common *wall-nut* 2. The great *wall-nut*, called the French and horse *wall-nut*. 3. The tender-fruited, or brittle-shell'd *wall-nut*. 4. The double-bearing *wall-nut*. 5. The harder fruited *wall-nut*. 6. The jagged-leav'd *wall-nut*. 7. The late ripening *wall-nut*. 8 The *wall-nut tree* with very small fruit 9. The *wall-nut tree* with plain, not ferrated leaves. *Turn.* Inst. p. 581.

NUX *maris*, in natural history, a name given by many writers to a peculiar species of sea shell It is one of the *dolium*, or *concha globosa* kind, and of that genus called *gondola*, and is the first species mentioned under that word. See GONDOLA.

NUX *regia*, the *royal nut*, a name given by some authors to the *walnut* C. *Bauhin*, Pin. p 417.

NYCTICORAX, in zoology, the name of a bird called in English the *night raven* It is of the heron kind, and is called by Mr. Ray *ardea cinerea minor*, or the small grey heron. It is much smaller, and shorter-neck'd, than the common heron; its head and back are black; its neck grey, and its throat and belly yellowish; it has on each side of the head a white streak from the angle of the beak to the eyes; and on the hinder part of its head has a crest made of three feathers, or hairy substances of five fingers breadth long: its wings and tail are grey: it flies principally by night, and makes a very hoarse and disagreeable croaking. *Ray's* Ornithol. p. 204.

NYCTOSTRATEGI, Νυκτοςρατεγοι, among the antients, officers appointed to prevent fires in the night time.

At Rome, they had the command of the watch, and, from their number, and office, were called *nocturni triumviri*. *Pitisc.* in voc.

NYGMA, a word used by some of the medical writers to express a wound by puncture.

NYMPHAGOGI, Νυμφαγογοι, among the antients, an appellation given to those who led the bride from her father's house, to that of the bridegroom. Vid. *Pitisc.* in voc. See BRIDE.

NYMPH (*Cycl.*) — NYMPHS *of flys*, in natural history, is that state of the fly class, which is between their living in the form of a worm, and their leaving that form for that of their parent fly. See Tab. of Insects, N° 29, seq.

In this state, in many genera of the flys, the worm, or maggot, makes a shell of its own skin, which hardens, and becomes brown, or redish, while the whole of its body becomes detached from it; and, after having lain some time in form of an oblong ball, without any visible parts of the creature that is to be produced from it, acquires, by degrees, the form of the fly, and all its limbs, and appears an embryo fly wrapped up in an extremely thin, and fine membrane. This is properly the *nymph* state, and, in these flys, when the parts of this *nymph* are more confirmed, and hardened, it is, in reality, no other than the fly wrapped up in this bag, which is so very transparent that every lineament of the insect it contains may be clearly discerned through it. The wings, however, in this state, appear as if they were not yet perfectly formed, but the truth is, that they are only very nicely, and regularly folded together. The creature, however, in this state, though ever so perfect, seems quite inanimate. When all the parts, however, have acquired their due strength, the creature puts itself into motion, and gets loose from its covering, which is no small difficulty; for though the skin of this is very fine and thin, yet as it serves as a nice case to every part of the animal, the effects by which it is to get rid of it must be somewhat difficult to the creature. A much greater difficulty, however, it will necessarily be imagined to be for the embryo fly to get out of the outer shell, or case, which is usually firm, hard, and rigid; but nature has so ordered it, that no more force shall be required for this great work than the creature is able to exert.

Out of the two forts of fhells of thefe infects, the one in form of an egg, and the other of the worm itfelf, there are two ways for the fly's egrefs.

For the firft of thefe, it is always from the fame end of the fhell, in form of an egg, that the embryo fly is feen to make its way out. This is always that end which is near the head of the fly, and which was, originally, the head of the worm. The head of the fly, however, is provided with no inftrument to make this great opening. The point of the trunk is yet very foft, and, even when at its utmoft hardnefs, it could only make a very fmall, and, in a manner, imperceptible hole. Nature has furnifhed the creature with another means of freeing itfelf from this fhell. The cap at the top of this is made, as it were, of two halves, and they fo loofely attached both to one another, and to the other part of the fhell, that they very readily feparate with a fmall force, and fall off from it. But this is not all; for in every one of thefe fhells, toward the joining on of the cap to the head part, there are two ribs, or prominent lines, diametrically oppofite to one another, and reaching to fome diftance in the fhell. Thefe feem formed to ftrengthen the fhell, but they are, in reality, intended to weaken it, and are the places at which it not only eafieft breaks, but even fplits, and opens, with a fmall force. This, with the falling off of the cap gives fufficient room of egrefs to the fly, and may be eafily difcovered to be intended fo to feparate by nature itfelf; fince in breaking any other part of the fhell, it cracks irregularly, and indeterminately; but here it feparates only at thefe lines.

It is eafy, indeed, for us by a flight force to feparate the two pieces of the cap of the fhell in thefe cafes, and a fmall force does it; but this, though fmall to us, is great in proportion to the ftrength and circumftances of the *nymph*, enclofed as it is on all fides.

The fkull of the fly, it is to be confidered, however, is folid and cruftaceous, and of a conftant and regular figure, as in other larger animals; yet the fly, in this ftate, is able to inflate and contract its head alternately, and, by that means effects much of the great bufinefs of its liberty. This extending the bulk of the head, is affifted by a fort of bladder which the creature, at each of thefe inflations, pufhes out to fome diftance from its head, and which, fometimes, even equals the head itfelf in fize. The air is the only means by which the fly can, in this manner, inflate and fwell its head; and, when neceffary, it fwells its whole body in the fame manner. The inflation of the head, and the throwing out this fort of bladder, which is an operation the fly is never able to do afterwards through its whole life, are evidently meant to diflodge and throw off the cap, and open the fide lines of the fhell. *Reaumur*, Hift. Infect. Vol. 4. p. 332, feq.

NYMPH-*animal*, in natural hiftory, one of the terms ufed by Swammerdam, in his claffing the infects according to their ftates and productions. It expreffes thofe creatures which are produced in their perfect form from the egg, and are fubject to no changes of any kind afterwards. See TRANSFORMATION *of infects*.

NYMPH-*chryfalis*, or NYMPH-*aurelia*, a name given by Swammerdam in his hiftory of infects, to one of the four general claffes into which he has reduced all thofe animals in regard to their changes.

The creatures of this clafs are not hatched from the egg in their proper form, but in that of a worm, or caterpillar, and, after hatching, they obtain their perfection by flow degrees, not as the *nymph* vermicles of the grafhopper do, in a manner obvious to the eye, but under the covert of their fkin, and muft appear chryfalis's before they are perfect flies. The common day and night butterflies, and many other infects are of this clafs. *Swammerd.* Hift. Infect.

NYMPHA *vermiculus*, in natural hiftory, a term ufed by Swammerdam to exprefs one of the four general claffes of the tranfmutations of infects, or, as he more properly ftiles them, their manner of growth.

The animals of this clafs are not produced from the egg in their perfect figure, nor yet in the worm fhape, as the caterpillar of the butterfly, and maggot of the fly, but the parts of the infect are imperfectly fhaped in the egg, and, after hatching, it does not appear properly itfelf, but acquires its perfection vifibly by means of outward food. The locuft, grafhopper, &c. are of this clafs. *Swammerd.* Hift. Infect.

NYMPHA *vermiformis*, in natural hiftory, a word devifed by Swammerdam, and by him ufed to exprefs one of his four great claffes on infects, according to their production.

Thofe of this clafs are not hatched from the egg in their own form, but in the fhape of worms, and differ from the caterpillar kind in this, that they always remain fhut up in the fkin of the worm, till they throw off both fkins at once, and appear in their winged ftate. The common flies, &c. are of this clafs. *Swammerd.* Hift. Infect.

NYMPHÆA, the *water lilly*, in botany, the name of a genus of plants, the characters of which are thefe: The flower is of the rofaceous kind, confifting of feveral petals arranged in a circular form; the feed veffel arifes from the cup of the flower, and is, when ripe, of a globofe or conic figure, multicapfular, and filled with oblong feeds. See Tab. 1. of Botany, Clafs 6.

The fpecies of *nymphæa* enumerated by authors are thefe: 1. The great white *nymphæa*, or *water lilly*. 2. The great American *water lilly*, with very large rounded leaves, beautifully crenated, and purple underneath, and with large white flowers. 3. The American *nymphæa*, with fmaller rounded leaves, obtufely crenated, green underneath, and with white flowers. 4. The fame fpecies of *water lilly* are known when not in flower, by their large leaves, which float upon the furface of the water. *Tourn.* Inft. p 260.

NYMPHARENA, in natural hiftory, the name of a ftone found in the beds of fome rivers, and having the appearance of a fea horfe's tooth. Doubtlefs it was a petrified tooth of that or fome other fuch animal, fuch things being often found now, though in thefe early ages they were little known or regarded.

NYMPHARIUM, in botany, a name given by the Greek writers of the later ages to the *water lilly*.

The word is formed of *nymphæa*, and is of the fame kind with many other names of plants devifed about the fame time, which feem a fort of diminutives formed on the before received names of the fame plants. Thus *fcillarium* is a name given by Aëtius to the *fquill*, when the roots were fmall. Moft of thefe words were formed of the Arabian names of the things thofe new ones expreffed.

NYMPHARUM *oculi*, in natural hiftory, a name given by fome of the antient writers to the ftone we call *oculus Beli*, and fometimes to the operculum of a fhell-fifh, common on the fea fhores in many places, and called *umbilicus veneris*. We are told of Caligula that he carried his foldiers armed to the fea fide, to pick up the *nympharum oculi*, and fhells. It is certain in this place, the word only means the *umbilicus veneris*, for the other *oculi nympharum* are found only on the fhores, and in the beds of fome particular rivers, not on the fea fhores among fhells.

NYMPHOIDES, in botany, the name of a genus of plants, approaching to the nature of the water lilly, or *nymphæa*, in external appearance, and thence ufually efteemed fpecies of that genus, but improperly.

The characters of this genus of plants are thefe: the flower confifts of one leaf, ufually of a rotated form, and divided into feveral fegments at the edge. The piftil arifes from the cup, and perforates the bottom of the flower, and finally ripens into a foft fruit, or capfule, of an oblong, compreffed figure, having only one cell, and containing many feeds wrapt up in a calyptra. See Tab. 1. of Botany, Clafs 2.

The fpecies of *nymphoides* enumerated by Mr. Tournefort are thefe: 1. The common *nymphoides*, which fwims on waters: this is called by moft other authors the *yellow water lilly*, with fimbriated flowers. 2. The *nymphoides* with leaves beautifully ftained with purple fpots. 3. The Indian *nymphoides*, with white fimbriated flowers, called by authors *nadil ambel*. *Tourn.* Inft. p. 153.

NYSSA, in botany, the name of a plant defcribed by Gronovius, and made by Linnæus a diftinct genus of plants, under the fame name. The characters are thefe: it produces male and female flowers; in the male flower the cup is a five-leaved, expanded perianthium. The flower is monopetalous, but divided into five fegments, of the fhape and fize of thofe of the cup. The ftamina are ten pointed filaments, longer than the flower. The antheræ are double.

In the female flower the cup is of the fame figure as in the male, but it remains upon the fruit. The flower is the fame as in the male; the piftil has an oval germen under the cup; the ftyle is fingle, and flender, and is longer than the flower. The ftigma is oblong, compreffed, and bent. The fruit is a drupa of an oval figure, containing one cell, in which is contained an oval nut, fharp pointed at the ends, and rib'd with longitudinal lines. *Linnæi* Gen. Pl. p. 482. *Gronov.* Virgin. p. 121.

O.

O (*Cycl.*) — It was not, ſtrictly ſpeaking, the letter O, but the figure of a circle ○, or double ○○, by which the modern antients, in muſic, uſed to expreſs what they called *tempo perfetto*, or triple time. Hence the Italians call it *circolo*. This circle was ſometimes pointed, and ſometimes barred, thus

 or thus, 

But theſe equally ſignified a triple time. *Broſſard.*

The ſeven antiphones, or alternate hymns of ſeven verſes, &c. ſung by the choir in the time of Advent, was formerly called *O*, from their beginning with ſuch an exclamation.

OAK, *quercus*, in botany. See the article QUERCUS.

Holm-OAK. See the article ILEX.

OAK-*apples*, a name given to the common galls, uſed in dying. See the article GALL.

OAK-*leaf galls.* Theſe are of ſeveral kinds; the remarkable ſpecies called the muſhroom gall, is never found on any other vegetable ſubſtance but theſe leaves; and, beſide this, there are a great number of other kinds.

The double gall of theſe leaves is very ſingular in that, as the generality of productions of this kind affect only one ſide of a leaf, or branch, and grow all one way; this kind of gall extends itſelf both ways, and is ſeen on each ſide of the leaf, in form of two protuberances, oppoſite the one to the other. Theſe are of differently irregular ſhapes, but their natural figure ſeems that of two cones, with broad baſes, and very obtuſe points, though ſometimes they are round, or very nearly ſo. See Tab. of Inſects, N° 25.

Theſe make their firſt appearance on the leaf in April, and remain on it till June, or longer. They are at firſt green, but afterwards yellowiſh, and are ſofter to the touch than many other of the productions of this kind: they are uſually about the ſize of a large pea, but ſometimes they grow to the bigneſs of a nut. When opened, they are found to be of that kind, which are inhabited each by one inſect only, and each contain one cavity. The cavity in this is, however, larger than in any other gall of the ſize, or even in many others of three times the ſize; the ſides of it being very little thicker than the ſubſtance of the leaf.

It would be natural to expect, in this large lodgment, a large inſect, but what is uſually found is only a ſmall browniſh ſubſtance, of a kidney-like ſhape, looking like the ſeed of ſome plant. This is hard and motionleſs; but is, however, the chryſalis of an inſect which may be found living in the gall, when opened in an earlier ſeaſon, and is a ſmall white worm, owing its origin to the egg of a fly. This creature has a method of depoſiting its eggs within the ſubſtance of the leaf, and the young ones, when hatched, eating on each ſide, form the double tumor.

The life of the creature in this ſtate is but ſhort, and its duration in the chryſalis conſiderably long. The ſhell under which it paſſes this ſtate is not made in the manner of that of moſt other worms, of its own ſkin, but is formed of the woody fibres of the ribs of the leaf, which it gnaws into ſmall pieces, and forms into that ſhape by means of a viſcous humour, ſecreted from its own pores. At length the fly makes its way out of this caſe by breaking off one end of it, and then eats itſelf a paſſage through the gall, and flies at large. The flies hatched of theſe inſects are very ſmall, yet Mr. Reaumur has obſerved them ſo carefully, as to be able to diſtinguiſh three or four kinds of them.

The moſt common fly produced of theſe galls, is a very beautiful ſmall one, of the four-winged kind. Its body and breaſt are black; its wings gawſy, and colourleſs; and its antennæ conſiderably long, and of the conic, granulated kind. The body of this fly is very ſhort. A ſecond ſpecies is very different from this firſt; it is of a brown colour, much longer bodied, and has antennæ of the club kind. There is another which reſembles this in ſhape, but its body is of a fine ſhining green, with an admixture of a gold colour; the wings of this exhibit all the rainbow colours in the manner in which they are ſeen on a bubble of ſoap ſuds.

It is not eaſy to aſcertain the origin of the ſeveral ſpecies of flies, which are, at times, ſeen in this manner to come out of the ſame ſpecies of galls. It ſeems the common courſe of nature, that only one ſpecies of inſect forms one kind of *gall*; yet it may be, that two or three kinds may give origin to the ſame kind. There is, however, another occaſion of our ſeeing different ſpecies come out of different *galls* of the ſame kind; and this is the effect of the enemies of the proper inhabitants.

It might appear that the parent fly, when ſhe had formed a *gall* for the habitation of her worm offspring, had placed it in an impregnable fortreſs: but this is not the caſe; for it frequently happens that a fly as ſmall, perhaps, as that which gave origin to the *gall*, produces a worm which is of the carnivorous kind, as the other feeds on vegetable juices. This little fly, well knowing that where there is one of theſe protuberances on a leaf, there is a tender and defenceleſs inſect within, pierces the ſides of the *gall*, and depoſits her egg within it. This, when it hatches into a worm, feeds upon the proper inhabitant, and, finally, after devouring it, paſſes into the chryſalis ſtate, and thence appears in the form of its parent fly, and is ſeen making its way out of the *gall*, in the place of the proper inhabitant

On opening theſe *leaf galls*, which are properly the habitation only of one animal, it is common to find two, the ſtronger preying upon the body of the other, and ſucking its juices as it does thoſe of the leaf; often it is found wholly employed in devouring its unoffending neighbour at once: this is probably the caſe when its time of eating is nearly over; and, in fine, when we find the *gall* inhabited by only one inſect, or containing only one chryſalis, as it ought in its natural ſtate to do, we are never certain that this is the proper inhabitant, as it may be one of theſe deſtroyers who has eaten up the other, and ſupplied its place. *Reaumur's* Hiſt. Inſ. Vol. 6. p. 197, ſeq.

OAK *puceron*, a name given by naturaliſts to a very remarkable ſpecies of animal of the *puceron* kind. The generality of ſuch animals live on the ſurface of the branches and leaves of trees, and plants; but theſe bury themſelves in the clefts of the *oak*, and ſome other trees, and getting into the crevices, where the bark is a little ſeparated from the wood, they there live at eaſe, and feed to their fill, without being expoſed to their common enemies.

Theſe are the largeſt of all the ſpecies of *pucerons*; the winged ones are nearly of the ſize of a common houſe fly, and the naked, or ſuch as have no wings, though leſs than theſe, are yet greatly larger than any other ſpecies of *pucerons*; the winged and naked kinds in theſe, as well as in the other ſpecies of *pucerons*, are all mothers, and great number of young ones may be preſſed out of the body of either kind, when gently ſqueezed. The winged ones are black, and the others of a deep brown, or coffee-colour; they have the moſt remarkable trunk of any animal in the world; it is more than twice the length of their bodies, and has not its origin at the extremity of the head, as in other inſects, but is fixed into the breaſt near the origin of the firſt pair of legs. When the creature is walking, it carries this ſtrait along the belly, and trailing a conſiderable length behind it, but with the point turned up, that it may be out of the way of accidents, and be ready to ſuck. When the creature has a mind to ſuck a part of the tree that is juſt before it, it draws up, and ſhortens the trunk, till it brings it to a proper length, and direction; but when it ſucks in the common way, it crawls upon the inner ſurface of the bark, and the turned up end of the trunk, which reſembles a tail, fixes itſelf againſt the wood that is behind it, or contiguous to its back, and ſucks there. The extremity of this trunk holds ſo faſt by the wood, that when it is pulled away, it frequently brings a ſmall piece of the wood away with it.

The ants are as fond of theſe as of the other ſpecies of *pucerons*, and that for the ſame reaſon, not feeding upon them, but on their dung, which is a liquid matter of a ſweet taſte, and is the natural juice of the tree, very little altered. Theſe creatures are the ſureſt guides where to find this ſpecies of *puceron*; for if we at any time ſee a number of theſe crawling up an *oak* to a certain part, and there creeping into the clefts of the bark, we may be aſſured that in that place there are quantities of theſe *oak pucerons*.

The mechaniſm by which this trunk of the *oak puceron* is ſhortened, is like that by which we alter at pleaſure the length of our teleſcopes which are compoſed of ſeveral parts running one into another. This trunk is, in the ſame manner, compoſed of three joints, which, at the pleaſure of the animal, are received more or leſs into one another's cavities, and, in all ſtates, are ſo flexile, that the animal can bend, and direct them to any part at pleaſure.

The laſt joint of the trunk, or that which is fartheſt from the body is terminated by a very hard and ſharp point; it is made only to pierce into the ſubſtance of the hard wood, and as, if this had been hollow, it muſt have been both weaker, and thicker, both which are great diſadvantages in regard to its uſe, nature has made it ſolid. In this it departs from the general nature of other trunks of inſects, which are always open at the end: but inſtead of that, this has an oblong ſlit on its upper part, a little above the end; by this means, it is able at once forcibly to enter the wood, and to imbibe its juices. This ſlit is not to be perceived without the largeſt magnifiers, but there is always to be ſeen a drop of tranſparent liquor on the place where it is, if the creature be a little ſqueezed when newly taken off from the wood.

This whole trunk is beautifully tranſparent, and there are two long bodies like hairs ſeen within it. It is hard to gueſs at the

the uses of so minute parts, but, probably, these serve either to assist the motions of that trunk in lengthening, or shortening, or else as pistons, in drawing up the juices for food.

Though the trunk already described appear very singular in this insect, there is something in the mechanism of the parts by which it receives its nourishment still more wonderful, more out of the common method of nature than that: this is, that the creature has, properly speaking, a double trunk, for it has, beside this long one, another which is shorter, being about the lengthened diameter of those of the other insects of this kind, and placed, as they are, at the extremity of the head. The creature can elevate, and protend, this lesser trunk at pleasure, but, in its natural state, it is lodged in a small channel, in the long and large trunk before described, made to receive it. The use of this seems very plain, though very singular; as the creature was to feed upon the juices of a hard and solid wood, it required an organ of peculiar strength to enter its substance; this nature has provided it with in its long trunk, but, as the uses that was destined for required its being placed on the breast, this was a p rt too far distant from the head to be proper for the receiving the juices. This scheme of nature for the nourishment of the animal, seems therefore to have been this; the larger trunk is to receive, and convey to its upper part, the juices of the tree, and the smaller trunk is there to be inserted at pleasure into it, and to suck up from thence the juice into the body, as, in common cases, its office is to do it immediately from the plant itself. *Reaumur*'s Hist. Inf. Vol. 6. p. 64, 78.

The ants are so extremely fond of the juices of the tree, when prepared for them by passing through the body of this animal, that when the *puceron* has a drop not yet evacuated, but hanging only in part out at the passage, an ant will often seize on it there.

The distinguishing characters of the *pucerons* of all kinds, is their having two passages for the excrements on the hinder part of the body, beside what resembles the anus in larger animals; these passages, in most species, are formed into a sort of horns, or short hollow tubes, sticking out from the body of the creature, and serving as a very obvious distinction of it from all other animals: in this, however, and in some other species, these passages are not formed into horns, but are only two round tubercles a little more elevated than the rest of the surface of the body, and placed where the horns in others stand. *Reaumur*'s Hist. Inf. Vol. 6. p. 78.

OAK *snake*, in zoology. See DRYINUS.

OAT, *avena*, in botany. See the article AVENA.

Some physicians have greatly recommended a diet drink made of *oats*, in various distempers. The method of preparing the drink is as follows: take of recent *oats* entire, and well washed, one pound and an half; of the fresh root of succory, cut into slices, one handfull; spring water twelve pints; boil all together in a clean earthen vessel to the consumption of half, and then strain the liquor through a linnen cloth, and add to it six ounces of coarse sugar, and half an ounce of sal prunellæ; let it boil again, and afterwards be taken off the fire, and set by, for a day and a night, in a cool place; then pour off the clear liquor, and keep it in a cellar in vessels close stopped.

Two ordinary cup-fulls of this liquor given twice a day, three hours before, and as many after dinner, are said to do wonders in the cure of all kinds of fevers, colic pains, pleurisies, itches, cutaneous tumors, and hypocondriacal disorders; as also in cleansing the kidnies from sand, and opening the obstructed viscera. The use of it is ordered to be continued thirteen days, and, if the patient be cacochymic, a gentle purge is to be given before it is taken. It is accounted a great preservative against illness, if taken thrice a year, in spring, in autumn, and in the dog days; and the inventor of it, Joannes de St. Catharina, is said to have kept himself alive by it to the age of an hundred and twenty years, without any disease.

Dr. Lower having tried it, and found its good effects, by repeated experience, made it public, and the celebrated Hoffman has written an express treatise about it, in which he recommends it both in intermittent and continued fevers, but advises purified nitre to be used instead of the sal prunellæ, and observes that the two boilings ordered by Dr. Lower are not necessary, but that the sugar and nitre may be added at first. It must be kept carefully in summer, otherwise it soon becomes sour, and unfit for use.

Those who desire to have it coloured may boil in it an ounce of alkanet root, and two ounces of red saunders, which will give it a fine red colour, without at all affecting its virtues.

It is, unquestionably, a very valuable medicine, affording singular relief wherever obstructions of the vessels are to be removed, or salts to be washed out of the habit; where the viscid juices are to be diluted, or a due degree of moisture, and humidity restored. It is also excellent for allaying thirst in fevers, and for stopping hæmorrhages.

Black OATS. These are commonly sown upon an etch crop, or on a lay, which they plough up in January, when the earth is moist, taking care to turn the turf well, and to lay it even and flat. *Oats* are to be sown earlier in the northern parts of England than in the southern.

Oats are sown with a broad cast at twice as they do barley, harrowing it well in; but this must always be harrowed the same way that the furrows lie of a lay, or but very little cross, for fear of raising the turf, but upon an etch, as soon as the land is ploughed on an edge, they sow and harrow it in once; then sow it a second time, the full quantity, and harrow it five or six times over, observing to harrow once or twice across, which breaks the clods, and covers the seed better than harrowing all one way. They commonly sow them upon a broad ridge, which they give the land but one ploughing for.

The usual time of sowing black *oats* is in the beginning of February, or a very few weeks later, sometimes not till the beginning of March: they are a hardy grain, and will bear any thing of wet or cold. Four bushels of seed is the qu ntity for an acre; but they grow best on a moist land, though they will not miss any where. The farmer knows that his *oats* are ripe when the stalk turns yellow, the grain feels hard and the husk begins to open, and shew the seed. After they are cut, they should lie for the dew and the rain to plump them, and make them thrash well; and, if weedy, to kill the weeds: but, if there happen much rain, they must be got in again as soon as dry, otherwise the *oats* will soon fall out of the husks, and great part of the crop be lost.

Red OATS. The red *oat* is a kind of corn very common in Staffordshire, and some of the northern counties; it is a sort of naked *oat*, and is very proper for making oatmeal, because the kernel thrashes out of the hull, without carrying it to the mill, or drying of it. This *oat* is cultivated in the same manner as barley.

White OATS. This kind of *oat* is commonly sown upon an etch, after wheat, rye, or barley: they only give the land one ploughing, and sow them, and harrow them, as they do the black *oats*, except the land is subject to weeds; in that case it is good to plough up the wheat, or rye stubble, in November, which will make it rot the better, and be a kind of winter fallowing. Only if you have a very dry burning ground, which black *oats* will not delight in, in that case, they often sow them upon a lay. March and April are the usual time of sowing white *oats*, and the drier the weather is when they are sown, the better; they grow best upon a dry, gravelly, or sandy land, and they are the best of all to be sowed upon a land very subject to weeds, because, being sowed late, they allow a very late ploughing, and growing very quick after this, they over-top the weeds sooner than any other plant. The reaping of white *oats* is the same with that of the black, and they generally yield about the same quantity, that is, twenty bushels, or thereabouts, from an acre. *Mortimer*'s Husbandry, p. 134.

Wild OAT, in husbandry, a kind of *oat*, or *oat* grass, which comes up of itself, without sowing, and is much hated, and dreaded by the farmers. This, in many counties of England, is the greatest of all hinderances of the good crops of barley, and often of other grain. It is a rough and hairy *oat*, and usually black. In the wetter years, and after much frost, this is found to be most troublesome.

The best remedy the farmer has against this, is to sow the land most apt to produce it with beans, and when they are come up to about three inches high, to turn in sheep upon the ground, about twenty sheep to an acre; these will eat up all the shoots of the wild *oat*, and not touch the beans so long as there is any of the *oat* shoots left. *Morton*'s Northampt. p. 480.

OAT-*snail*. See the article SNAIL.

OBELISCUS *marmoreus*, in natural history, the name of a very remarkable species of shell-fish, unknown to us in its recent state, but met with very frequently fossile in the Swedish stone used for pavements, and in some other kinds, and more accurately named by late authors *polythalamium*, and *orthoceratites*, and by Klein *tubulus marinus concameratus*. *Klein*. de tubul. p. 7. See TUBULUS *concameratus*.

OBELISK (*Cycl.*) — One of the uses of *obelisks* among the antients, was to find the meridian attitudes of the sun, at different times of the year. Hence they served instead of very large gnomons. One of the *obelisks* now standing at Rome, that of St. John's Lateran, is, in height, 108 English feet, without the pedestal; and the other *obelisk*, buried under the *campo Marzo*, wants but little of the same height. Pliny gives us a description of this gnomon, lib. 36. §. 15. From him it appears that there was laid down, from the foot of the *obelisk* northward, a level pavement of stone, equal in breadth to the breadth of the *obelisk* itself, and equal in length to its shadow at noon, upon the shortest day; that is to say, that its length was to the height of the *obelisk*, almost as 22 to 10, and that, under this pavement, there were properly let in parallel rulers of brass, whose distances from the point, directly under the apex of the *obelisk*, were respectively equal to the lengths of the shadow thereof at noon, on the several days of the year, as the same lengths decreased from the shortest day to the longest, and again increased from the longest day to the shortest. Vid. Phil. Transf. Nº 482. Sect. 5. where we also find some remarks by Mr. Folkes on Hardouin's amendment of a passage in Pliny's natural history, lib. 2. §. 74. Edit Parif. 1723. fol. about the length of the shadows of gnomons in different latitudes.

OBEY, in the manege. A horse is said to *obey* the hand and heels, to *obey* the aids, or helps, when he knows and answers them according to demand.

OBLADA, in ichthyology, a name given by ſome to the *melanurus* of authors, a fiſh of the *ſparus* kind, diſtinguiſhed by Artedi by the name of the *ſparus variegated with longitudinal lines, and with a large black ſpot on each ſide near the tail.*

OBLATÆ (*Cycl.*)—Oblata is alſo a word uſed by ſome authors to expreſs a ſort of purging tablet, made of fine flower and ſugar, with ſome purging ingredients.

Oblatæ is alſo uſed to ſignify the conſecrated wafers, or hoſts, diſtributed to the communicants in the maſs or ſacrament of the altar; and ſometimes the cuſtomary treats in religious houſes have been called by the name of *oblatæ*.

OBLIGATO, in the Italian muſic, ſignifies *for*, *on purpoſe for*, or *neceſſary*, as *doi violini obligato*, on purpoſe for two violins; and ſo of other things, as *conſagotto obligato*, that muſt be played with a baſſoon, &c.

Sometimes it ſignifies confined, or reſtrained, by certain rules, ſubjected to certain limits or laws, in order to perform ſome particular thing, to give ſome particular expreſſion of a paſſion, action, &c. In this ſenſe we ſay, *contrapunto obligato*, *fuga obligata*, &c. We alſo ſay, the baſs is *obligato*, when it is only a ground of a certain number of bars, which are to be repeated over and over; ſuch is the baſs to chacones, &c. and every baſs wherein one is obliged to keep a certain movement, and to perform only certain notes, &c.

OBLIGEE, in law, is the party to whom an obligation, or bond is made. *Blount.*

OBLIGOR, in law, the party who enters into, or executes, an obligation, or bond.

OBLIQUE (*Cycl.*) — Oblique *circle*, in the ſtereographical projection of the ſphere, any circle that is *oblique* to the plane of projection.

OBLIQUO, in the Italian muſic, ſignifies two breves tied together, which make but one body, whence it is named in Italian *nota d' un corpo ſolo*; ſometimes there is a tail, or the right, or left ſide, either aſcending, or deſcending. (See Note, Ligature, and Virgula.) However it be, the two extremes mark the ſound, the middle ſerves only to tie them, thus:

OBLIQUUS *brevis*, in anatomy, a name given by ſome authors to the muſcle uſually called the *obliquus inferior oculi*, the *ſextus oculi* of Fallopius.

Obliquus *externus*, in anatomy, the name of a muſcle of the abdomen, which is broad and thin, fleſhy on its upper and back part, and tendinous on the anterior, and greateſt portion of the lower part. It reaches from half the lateral and inferior part of the thorax, to almoſt half the lateral and ſuperior part of the pelvis: and from the back part of the regio lumbaris to the linea alba. It is fixed by its upper part to the ribs, by its lower to the os ilium, ligamentum Fallopii, and os pubis, and by the fore-part to the linea alba; the poſterior portion next the vertebræ of the loins has commonly no true muſcular inſertions. It is called alſo the *obliquus deſcendens*, *obliquus ſuperior*, and *obliquus major*.

It is fixed to eight ribs by the ſame number of angles, the inſertions in the bony extremities of the ribs are at different diſtances from the cartilages, and the name of digitations, or indentations, have been given to theſe angular inſertions, becauſe they join a like number of the ſame kind belonging to other muſcles, as the fingers of the hands may be locked between each other; theſe digitations appear to be entirely fleſhy, but they are almoſt all truly a little tendinous in their back part; they ſeem to encreaſe in breadth alſo as they deſcend, and often unite with the intercoſtal muſcles, as they paſs over them; there are in theſe muſcles other internal inſertions, covered and hid by thoſe which appear outwardly. The firſt digitation is longer than the reſt, and has about the breadth of two fingers; the ſecond is about an inch in breadth; the third is about three fingers broad; the fourth mixes, by ſome of its anterior fibres, with the ſerratus major, as the firſt does with the pectoralis major, and the ſecond with the ſerratus major; the fifth mixes both with the foregoing, and with the firſt digitation of the latiſſimus dorſi; the ſixth is about two fingers broad, and ſends off a faſciculus of fibres to the ſerratus major; and the ſeventh is of the ſame breadth with the former, and ſome of its fibres are ſent off to the ſerratus poſterius inferior. *Winſlow*'s Anatomy, p. 163.

Obliquus *internus*. This is another name for the *obliquus aſcendens*. It is a broad thin muſcle like the former, with nearly the ſame extent and inſertions, that is in the lower ribs above, in the criſta of the os ilium, and ligamentum Fallopii below, and in the linea alba before; but it differs from it in this, that the lower part of it is more fleſhy than the upper. One portion of its lower extremity, which is intirely fleſhy, is fixed by very ſhort tendinous fibres in the middle ſpace between the two labia of the criſta of the os ilium, from the back part of the tuberoſity of that criſta, near the ſymphyſis of the os ſacrum, almoſt all the way to the ſuperior, and anterior ſpine of the os ilium; ſo that its inſertion reaches farther back than that of the obliquus externus. The fleſhy fibres thus fixed run up firſt from behind, obliquely forward, and then this obliquity encreaſes proportionably, as the fibres lie more anteriorly, and they croſs thoſe of the fleſhy portion of the external obliquus, being afterwards inſerted exteriorly in the lower edges of the cartilages of all the falſe ribs, and thoſe of the two loweſt true ribs, reaching to the extremity of the cartilago enſiformis. *Winſlow*'s Anatomy. p. 165.

Obliquus *capitis ſuperior*, a muſcle ſituated laterally between the occiput, and firſt vertebra, and nearly of the ſame figure with the two recti. It is fixed to the end of the tranſverſe apophyſis of the firſt vertebra, from whence it runs upward, and very obliquely backward, and is inſerted in the tranſverſe line of the os occipitis, almoſt at an equal diſtance from the criſta, and the maſtoide apophyſis between the rectus major and the complexus minor, which it covers a little. *Winſlow*'s Anatomy, p. 237.

Obliquus *capitis inferior*, a muſcle ſituated in a contrary direction to the obliquus ſuperior, between the firſt and ſecond vertebræ of the neck, and reſembles the ſuperior in every thing but ſize. It is fixed below to one branch of the bifurcated ſpinal apophyſis of the ſecond vertebra, near the inſertion of the rectus major, from whence it runs obliquely, upward and outward, and is inſerted in the end of the tranſverſe apophyſis of the firſt vertebra, under the lower inſertion of the obliquus ſuperior. *Winſlow*'s Anatomy, p. 237.

Obliquus *capitis inferior* is alſo the name given by Albinus to a muſcle called by Winſlow *obliquus major*; and, by Veſalius, and the old authors, *ſextus capitis movVentium*. Fallopius makes it the *ſeptimus capitis*, and Euſtachius, in his treatiſe, *De motu capitis*, calls it *parvus muſculus a ſecundæ vertebræ ſpina in proceſſum tranſverſum ſpinæ obliquè inſixus*.

Obliquus *ſuperior oculi*, in anatomy, a name given by Albinus, and others, to the muſcle called *obliquus major*, and *tertius palpebrarum*, by others.

Obliquus *naris muſculus*, in anatomy, a name given by Winſlow to the muſcle ſince called by Albinus the *levator labii ſuperioris alæque naſi*.

OBLONG *leaf*, among botaniſts. See Leaf.

OBNUNCIATION, *obnunciatio*, in Roman antiquity. See Nunciation.

OBOE, or Oboi, in the Italian muſic, is uſed to ſignify an *hautboy* or *hoboy*, or that a part is to be played on that inſtrument.

OBRANG, in botany, the name given by the people of Guinea to a very ſingular and remarkable plant, the virtues of which they greatly praiſe. They boil it in water, and uſe the decoction by way of a fomentation to take down ſwellings of the teſticles. Its leaves have ſome faint reſemblance to thoſe of our liquorice, whence Petiver has called it *glycyrrhizæ folio ſingulari frutex Guineenſis ſpinis gemellis*. Phil. Tranſ. N° 232.

OBRIZUM, in antiquity, a kind of gold. Pliny ſays [a], that they call the gold that has been ſeveral times purified in the fire, *obrizum*. *Auri experimento ignis eſt ut ſimili colore rubeat quo ignis*; *atque ipſum* obrizum *vocant*. *Abriz* in Arabic, or Perſian, ſignifies fine gold without mixture, which the Greeks and Latins call *obrizum* [b]. — [[a] *Plin.* l. xxxiii. c. 23. [b] *Calmet*, Dict. Bibl.]

OBSIDIANUS *lapis*, in the natural hiſtory of the antients, the name of a ſtone which they have alſo deſcribed under the name of the *Chian marble*. It is a very ſmooth and hard marble, extremely difficult to cut, but capable of a fine poliſh, and was uſed among the antient Greeks for the making reflecting mirrors. See the article Chium *marmor*. The later writers have ſuppoſed the name *obſidianus* derived from ſomebody of the name of *Obſidius*, who was the inventor of this uſe of it; but it ſeems only a falſe ſpelling of the word *opſianus*, ἀπὸ τοῦ ὄψεως, from ſeeing the images of things in it. *Hill*'s Hiſt. of Foſſ. p. 460.

OBSTITA, among the Romans, a term uſed to ſignify places that had been thunder-ſtruck, which were otherwiſe called *bidentalia*. *Hofm* Lex. Univ. in voc. See Bidental.

OBSTRUCTION *of the bowels*, *obſtructio alvi*, in medicine, the name by which authors expreſs what we call *coſtiveneſs*, that is, a retention of the ſtools a longer time in the bowels than they ſhould be kept there, from whatever cauſe that retention happens.

An *obſtructio alvi* is ſometimes idiopathic, where there is no other diſeaſe concurring to it; ſometimes it is ſymptomatic, and depends entirely on other diſeaſes, as on fevers, congeſtions, and the like.

Signs of Costiveness. The firſt, and moſt obvious, of theſe is, the not going to ſtool in the ſpace of twenty-four hours; this is uſually ſucceeded by a dizzyneſs, and vertiginous diſorder of the head, painful congeſtions of blood about the head, flatulencies, oppreſſions of the ſtomach, and ſtraitneſs and anxiety about the præcordia. *Junker*'s Conſp. Med. p. 590.

Perſons ſubject to Costiveness. Men of ſedentary, and idle lives, are more ſubject than others to this complaint, eſpecially when ſubject to commotions of the blood, and of a dry choleric temperament, and ſuch as are ſubject to hypocondriac

condriac affections, and to the gout, or to nephritic complaints, and to acute fevers.

Causes of COSTIVENESS. These are observed by writers to be of two kinds, the active, and the passive. The active cause is a certain stricture which comes on in the rectum in many different disorders; as in the stone, in nephritic complaints, and in general, in all the congestions of blood toward the upper parts of the body. What is called the passive cause of *costiveness*, is that occasioned by a sort of sluggishness in nature, which leaves the peristaltic motion of the guts too languid, on occasion of which the fæces are easily indurated in the bowels. The occasional and accidental causes which contribute to this induration of the fæces are the following: a neglecting the usual time of going to stool; and checking the natural tendencies, and motions toward it; an extraordinary heat of the body, and copious sweats; a larger quantity of solid food taken into the stomach than is proper for the quantity of fluids swallowed, and a common use of such food as is dry and hard of digestion.

Prognostics in COSTIVENESS. It is the origin of a great many disorders; and, in particular cases, is often attended with imminent danger. In choleric habits, in which persons are subject to large quantities of bilious matter being lodged in the primæ viæ, *costiveness* is usually attended with colics, and violent heats. The indurated excrements also, when they press upon the veins in the guts, very often prevent the circulation, and, by that means, bring on dangerous inflammations in the parts; and, in general, whatever disease is attended with *costiveness* is rendered worse and more violent by it.

Method of treatment in COSTIVENESS. An idiopathic *costiveness*, when grown into a habit by long sufferance, is best cured by means of drinking more liquids than usual, and giving the body a greater share of motion; but this motion must, by no means, be violent, for that always encreases the disease, but when placid and easy, it tends greatly to the restoring the peristaltic motion of the bowels to its proper state. To this it is to be added, that many people have restored themselves from this distemperature to a good state, only by going to the close-stool every day, at a certain hour, and only endeavouring for some time, but without great violence, to force a stool; the consequence of a continual practice of this, for some weeks together, has brought nature to expect it, and, in fine, to be prepared for it, and always to have fæces at the time ready to be discharged. The eating a small piece of bread with a large quantity of butter spread over it every day before dinner and supper is also a good custom; and purges taken every spring and autumn are a method of bringing nature into a proper course. When the case is violent, and calls for the assistance of medicine, there is always more benefit obtained from clysters, than from purging medicines given internally. These last, when given, must never be violent.

In a symptomatic *costiveness*, the primary disease is always to be first regarded, and this is, generally, not a little relieved by a proper removal of the *costiveness*. In chronic cases, the same rules are to observed as in the cure of the idiopathic *costiveness*; but, in acute cases, recourse is to be had to clysters, and large draughts of warm, and weak fluids, such as barley water, and the like.

When *costiveness* is attended with no other complaint, but people enjoy their perfect health with it, there is no occasion for medicines, nature being in some constitutions habituated to it, and doing well with it. There are many persons who, in general, do not go to stool oftener than once in three days; some once in a week; and there have been instances of people, who, while they have enjoyed a perfect health, and eat very heartily, have not gone above once in three or four weeks. When habitual *costiveness* is to be cured by motion, and drinking more fluids, these must be always used together; for otherwise drink alone more relaxes the bowels, and motion alone dissipates the already too little humidity. Thus either of them alone must add to the disease, which, when given together, they cure. The common method of attempting to cure *costiveness* by repeated doses of purges, brings on a great many inconveniencies, particularly they always leave the bowels more bound than before, and by that means add to the complaint they were meant to relieve, and even the gentlest purging medicines have this effect. *Junker's* Consp. Med. p. 391.

In cases of this kind, Dr. Huxham recommends a medicine prepared with salt of hartshorn, saturated with spirit of vinegar, which not only takes away the fœtid smell of the oil of the salt, but changes it into an agreeable aromatic. Obs. de aere, et morb. epid.

OBTUNDENTIA, a word used by some authors to express such medicines as are given to obtund, or edulcorate the acrimony of the humors.

OBTURATOR (*Cycl.*) — OBTURATOR *externus*, a small flat muscle, which fills up the foramen ovale of the os innominatum exteriorly, and reaches from thence to the great trochanter of the os femoris behind the neck of that bone. It is fixed by fleshy fibres to the outer, or anterior side of the os pubis, all the way to the foramen ovale, to the edge of that hole next the small ramus of the ischium, under the acetabulum, where a tendon is formed, which continues its course behind the neck of the os femoris toward the great trochanter, and is inserted between the gemelli, and quadratus, in a small fossula, between the apex of the great trochanter, and the basis of the collum femoris. *Winslow's* Anatomy, p. 211.

OBTURATOR *internus*, a flat muscle, almost triangular, situated in the bottom of the pelvis; it covers the foramen ovale, and almost all the inside of the os pubis and ischium. It is fixed to the internal labium of all the anterior half of the foramen ovale, a little to the neighbouring part of the *obturator ligament*, and also both above and below the foramen. It is likewise fixed to the upper half of the inside of the os ischium, from the upper oblique notch in the foramen ovale, to the superior part of the great posterior sinus of the os ilium.

From all this extent, the fleshy fibres contracting in breadth, run down below the spine of the ischium, where they go out of the pelvis through the posterior notch in the ischium. The inside of the body of this muscle, or that turned to the cavity of the pelvis, is pretty uniform; but the outside, or that turned toward the foramen ovale, and which touches the bone, has four middle radiated tendons, which uniting at the posterior notch of the ischium, run over it from behind forward, as over a pulley, each tendon sliding in a particular cartilaginous channel. Afterwards the four tendons having got out of the pelvis, are pretty strictly united in one large flat tendon, which, crossing over that of the pyriformis, unites with it, having first received on each side, some additional fleshy fibres from the two gemelli. The great tendon slides freely, in a sort of membranous vagina, formed by these muscles, and is inserted in the middle of the superior part of the cavity of the great trochanter, adhering closely to the capsular ligament of the joint, and being united to the tendons of the glutæus minimus, and pyriformis. *Winslow's* Anatomy, p. 209.

OBTURATOR *ligament*. This is one of the proper ligaments of the ossa innominata, and fills up all the great foramen ovale, except the oblique notch at its upper part. It is fastened precisely to the edge of the circumference of that hole, from the anterior part of the oblique notch, all the way to the symphysis between the os pubis, and os ischium. From thence to the posterior part of the inferior notch, it is fixed to the internal labium of the edge of the circumference, forming a kind of small channel with the external labium; and afterwards it is fixed to the common edge of the foramen ovale, and cotyloide notch. By this disposition, an opening is left between this ligament, and the superior oblique notch, and immediately below this common opening, there are two small perforations in the ligament alone. *Winslow's* Anatomy, p. 124.

OBULARIA, in botany, the name given by Linnæus to a genus of plants, the characters of which are these: there is no cup to the flower, but, in the place of one, there stand two leaves of the plant. The flower is composed of only one leaf; the tube is of a bell shape, inflated, and pervious, and the edge is divided into four segments, which are shorter than the tube, and are of a bifid figure. The stamina are four subulated filaments, arising from the segments of the flower, and two of them are somewhat smaller than the others. The antheræ are small. The germen of the pistil is oval, and compressed. The style is cylindric, and of the length of the stamina; and the stigma is oblong, bifid, and remaining. The capsule is of an oval, compressed figure, and contains numerous seeds, in form of a fine powder. *Linnæi* Gen. Plant. p. 297.

OCCATION, a term in the antient husbandry, by which they expressed what we do by harrowing, though they performed it with a different instrument, a kind of rake.

With the teeth of this instrument, they levelled the ground, and broke the clods, and, with the hand, strewed the corn over this level ground. Then they brought on the plough, and ploughed it in; so that the grain was sown in furrows, as we express it, and usually came up, as we see it does at this time with us, in the same case, in the lower parts only. After it had got a few leaves, they went over the ground again with the same instrument a second time, to clear away the weeds, and move the earth about the roots of the young plants. If they did this lengthways of the furrows, the earth being somewhat hardened, there fell but little of it among the corn; but if they did it crossways of the furrows, a great deal fell down upon, and among, the young plants, and, in a manner, buried them; they were usually observed to grow the better for this cross harrowing, except in cold places; and the husbandmen thought the vigour of the plants was owing to the burying them with new earth; but this was really rather prejudicial to them, and the advantage they had arose from the more deep stirring of the ground. *Tull's* Husbandry.

OCCHIO, in glass-making, the hole in the floor of the tower of the leer. *Neri's* Art. of Glass. p. 243.

OCCIDENS, an affected name given by some of the chemical writers to *vinegar*.

OCCIDENT, in geography, the westward quarter of the horizon, or that part of the horizon where the ecliptic, or the sun therein, descends into the lower hemisphere.

Equinoctial OCCIDENT, that point of the horizon where the sun sets, when entering *aries*, or *libra*.

Estival OCCIDENT, that point of the horizon where the sun sets at his entrance into the sign *cancer*, when the days are longest.

Hybernal OCCIDENT, that point of the horizon where the sun sets, when entering the sign of *capricorn*; at which time, the days, with us, are shortest.

OCCIPITAL (*Cycl.*) — The *os occipitis*, or *occipital bone*, is situated in the posterior and lower part of the cranium; it represents a kind of lozenge, irregularly indented, and is convex without, and concave within. It sometimes, but very rarely, is found to consist of two pieces, being divided, in that case, by the continuation of the coronal suture. It consists of an external, and internal side, of the upper, lower, lateral, and middle parts; the first four of which may be looked upon as so many angles; and has four edges, the two superior of which are indented, the two inferior are more or less unequal in different subjects. Near the middle of the convex outside of this bone, the *occipital* protuberance, or rising, is observable; under this protuberance are two superficial transverse arches; these are more remarkable in some subjects, than in others, one superior, and larger, the other inferior, and less, and both reaching to the mastoide process on each side: the inferior arch is cut at right angles by a perpendicular line, called the external, *occipital* spine, or crista. Under the superior arch are two rough planes, one on each side of the spine; and between the extremities of the two arches are two other such planes, one on the right hand, and the other on the left. We see likewise two condyles, or condyloide apophyses, crusted over with cartilages, gently convex, of an oblong oval figure, and situated obliquely; their posterior extremities being at a greater distance from one another than their anterior. Also a large, cuneiform, production, which, from the condyles, is directed upwards, and, in adults, is often joined inseparably to the os sphenoides. This may be termed the apophysis basilaris, or the great apophysis of the *occipital* bone. Lastly, there are some unequal tubercles on the lower part of this apophysis, and two little angular productions in the edge of the bone, over against the condyles.

There are likewise in this bone two large notches under the lateral angles, which receive the posterior apophyses of the ossa temporum, two small notches, or portions of the jugular fossæ, and of the foramina lacera; each of these is often divided by a small bony production: also the great *occipital* hole, on the anterior edge of which there is an impression for the insertion of a ligament, two anterior, and two posterior condyloide fossulæ, two anterior condyloide holes for the ninth pair of nerves, which are sometimes double, and two posteior condyloide holes for small veins, which are sometimes wanting. The upper part of this bone is thick, as being much exposed to blows, and other injuries; the lower part is thinner, but is well guarded by muscles. It forms the back part of the head; serves for the articulation of the head with the trunk; contains a part of the brain, and almost all the cerebellum; and gives passage to the medulla oblongata, and a great many of the nerves, and vessels; and insertion to a great many of the muscles. *Winslow's* Anatomy, p. 25.

OCCUPIERS *of walling*, a term in the salt works for the persons who are the sworn officers, that allot, in particular places, what quantity of salt is to be made, that the markets may not be over-stocked, and see that all is carried fairly and equally between the lord and tenant. These persons always appoint how many houses shall work at a time; and, when, there is salt to be made, these appoint a cryer to proclaim it to all the workers, that they may put to their fires at the same time; and a like proclaiming of the time when they shall leave off; and those who continue to work after this prohibition, are to have their salt spoiled, or destroyed. *Ray's* English Words, p 173.

OCELLATI *lapides*, in natural history, a name given by the antients sometimes to express certain stones, found on the shores, and in the beds of rivers, and naturally marked with the figure of an eye; and sometimes for small round stones of the shape of the globe of the eye, made by art for children to play with, and of the nature of what we call marbles. Suetonius tells us, that Augustus Cæsar used to divert himself sometimes with playing *nucibus et ocellatis*.

The word *lapidibus* is understood after the last word, and the meaning of the author plainly is, that he played, like a boy, with nuts and marbles. The word *ocellatus*, therefore, here, as in many other passages of the antients, plainly expresses those little round stones, formed by art, of little or no value, and intended only for boys to play with. But we have abundant testimony among the antient naturalists of the word having been used also as the name of the gem which we now call *oculus beli*, and all those other stones of the agate, or other semi-pellucid kinds, which had the figure of an eye naturally impressed upon them, that is, a round spot of a different colour, in the center of a small roundish stone. These were scarce among the antients, because they had none but the true *oculi beli*, or such stones as were of a particular species, and were found naturally of the shape and size of an eye; but we have them much more common, because our jewellers, whenever they find a natural spot in an agate, surrounded with a white circle, cut it out from the rest of the stone, and sell it as a natural *oculus beli*.

The name *ocellati lapides*, is not, by any means, a strange, or unnatural one for the genuine stones thus shaped, and marked with the resemblance of a pupil; for the antients used the name of the eye in a much larger sense, expressing by it any thing that appeared rounded and protuberant. Pliny, speaking of the Callais, or Turquoise stone, says, that it protuberated from the rocks in the form of an eye, and means no more by it, than that the masses of it were round, and prominent, as we see those of copper oreturquoise at this day.

OCHNA, in botany, the name of a genus of plants, the characters of which are these: the cup is a perianthium, composed of five small leaves, of an oval, but pointed shape, standing expanded, and falling with the flower. The flower is composed of two roundish petals, with very obtuse ends, and with ungulæ of the length of the leaves of the cup. The stamina are a number of fine slender filaments, converging at the ends. The germen of the pistil is oval, and terminates in a pointed style, which is erect, and longer than the stamina. The fruit is a very large, and fleshy receptacle, of a roundish, truncated form, in either side of which there is lodged a single berry, of an oval figure. The seeds are single, and of an oval figure also. *Plumier*, 32. *Linnæi* Gen Pl. p 819.

OCHRA, or *gallinula* OCHRA, in zoology, the name of a species of moorhen. It is all over of a dusky, and obscure, yellowish green, and is browner on the breast, and belly, than on the back, yet with the same yellowish green predominant. The head, neck, breast, and wings, have several white spots; and the face is in part white; the beak is part black, and part red; and the legs are of a yellowish colour. *Aldrovand.* de Avib. l. 20. c. 48.

OCHRA *vitrioli*, in natural history, a name given to that yellow earth, or *ochre*, which is one of the principles, or constituent parts of all vitriol. This is separated from it by solution in water, and falls to the bottom of the vessel; and the yellow substance that tinges the sides of fountains, and springs of chalybeat waters, in many places, is the same substance, and shews that they are only solutions of vitriol, which, as such, must needs deposit that earth, which, though retained imperceptibly in the vitriol, yet cannot be sustained in water so well as while that salt was solid.

Basil Valentine tells us, that repeated solutions of the same quantity of vitriol, will, at length free it from all its earth; and that then it will be found a very different substance from what it was before, and fit for several wonderful experiments, which he describes. This separation of the earth of vitriol has been tried in vain, by twenty repeated solutions; but there is a much shorter way of effecting it, which is this: Powder a good quantity of Dantzick, or Hungarian vitriol; put it into a high and narrow cucurbit, and add to it a considerable quantity of water; keep a fire under it for four days, and the earth will, in a very great quantity, subside from it, when cold, in much greater quantity from this one operation, than from several repeated ones of the common kind.

Another method, which separates more than its earth from it, is this: Let the vessel containing the powdered vitriol, without any addition of water, be placed in a balneum Mariæ, and kept hot in the same manner for four days; the vitriol will, in this case, melt as if water were put to it. While it continues in this fluid state, the *ochre*, or earth, and not only that, but with it, the metalline parts, and the gross sulphur, will in a great measure subside, and become a hard cake, the vitriol continuing fluid about it Let this be poured off, and when cold, it will crystallize, leaving only a small quantity of a liquamen behind. This operation may be repeated two or three times, and the vitriol then becomes a very different substance from what it was before, and is fitted for several operations, which it would not otherwise succeed in. Many have tried to effect this separation by liquation, by means of a dry heat, placing the vessel in sand, in filings of iron, or over the flame of a lamp, burning spirit of wine, or oil; but it never will succeed this way, though the vitriol be ever so long kept in a state of liquation. Phil. Trans. N° 103.

The *ochra vitrioli* may be obtained also in a great proportion, though in another form, if, after a long, and intense calcination, the vitriol is freed from its salt by an ablution of warm water often repeated The far greater part of the remaining colcothar, thus dulcified, is earth, with an admixture only of a small quantity of some metalline parts.

Another way of obtaining it, is dissolving vitriol in common water, and adding to the solution filings of zink, or salts of tartar, or some other alkali. See the article VITRIOL.

A great proof of the earth called *ochra vitrioli* being contained in large quantity in that salt, is, that it requires no earth beside to be mixed with it in distillation: whereas common salt, nitre, and the other salts, require a great quantity of common earth to be added to them, to prevent their fusion.

Alum,

Alum, and vitriol alone, require no such additions, the first of these containing a very large quantity of an alkalious, white earth, as the other does of an ochreous yellow one.

OCHRES, in natural history, the name of a large genus of earths, used principally by the painters. The most common kinds are either yellow, or red, though there are brown, blue, and green *ochres*, and a number of distinct species of all these colours. Of the yellow *ochres*, Dr. Hill, in his history of fossils, describes eleven species. Of the red, the same number. Of the brown two. Of the blue, and green, one species each; and of the black, two.

The greater number of these are, or have been, at one time, or other, in use in painting, in different parts of the world. Some, however, there are, especially of the yellow and red kinds, which that author has, himself, discovered in different parts of our own, and other kingdoms, which are worthy the tryals of the persons concerned in that branch of trade, as they have already been proved, at his request, in small quantities, and found to answer very well. *Hill's* Hist. of Foss. p. 51.

The species of the yellow *ochres* are these: 1. The *ochra levissima, friabilis, pallidissime flavescens*; or very light friable pale yellow *ochre*. An earth found of late years in Pensylvania, Virginia, and some other of our American plantations, which has been tried both in water, and oil, and makes a very pale straw colour in the former, and a fine yellow, though somewhat deeper, in the latter; but making no good colour, when burnt.

2. The *ochra ponderosa, dura, pallide flavescens*; the hard, heavy, pale, yellow *ochre*. This is found in Germany, Saxony, France, and England, and is well known to the painters, and much used by them for a pale yellow. They call this French *ochre*; but it is dug in considerable quantities in Dorsetshire. This makes but a dull colour, when burnt, and is, in its native state, much inferior to the common kind.

3. The *ochra levissima, flava, friabilis*; the light, crumbly, yellow *ochre*. This is frequently thrown out at the mouths of chalybeate springs, and, sometimes, from such as are not manifestly impregnated with the particles of that metal; and is found in great abundance on Hampstead heath. This is not used by the painters, but is a bright yellow, and very fine, and is, therefore, worth trying.

4. The *ochra levis, aurea, friabilis*; the light, friable, gold-coloured *ochre*. This was the *ochre* of Theophrastus, and of the earliest ages we have accounts of. It is common in our gravel pits, in large loose lumps. The painters of the present age are not acquainted with this; but it is a very valuable substance, making a fine strong yellow in its native state, and a very bright, and beautiful red, when burnt. *Hill's* Hist of Foss. p. 52.

5. The *ochra crocea, laminata, levis*; the light, plated, saffron-coloured *ochre*. This was also well known to the antient painters, though not so early as the former, and is the Attic, or Athenian, *ochre* of Dioscorides. It is, like the former, common in small plated masses, in our gravel pits, and, though not known to our present painters, has been tried, and proves a very fine yellow, both in water, and oil, in its native state, but does not make a bright red, on burning. *Hill's* Hist. of Foss. p. 53.

6. The *ochra ponderosa, flava, friabilis*; the heavy, friable, yellow *ochre*. This is common in England, and is well known, and very much used in its native state among the painters. It is dug in Buckinghamshire, Somersetshire, and Oxfordshire, but is greatly inferior to the two former kinds. *Hill's* Hist. of Foss. p. 54.

7. The *ochra argillacea, ponderosa, lutea, dura*; the hard, heavy, clayey, yellow *ochre*. This is dug in Buckinghamshire, Yorkshire, and some other counties, and is sent up to London, and used by the painters, making a very lively yellow in its native state, and a pleasant, though not a strong red, when burnt. *Hill's* Hist. of Foss. p. 55.

8. The *ochra durissima, ponderosa, flava*; the stony, hard, and heavy, yellow *ochre*. This is well known to the painters, and much valued by them. It is dug in Buckinghamshire, Staffordshire, and Yorkshire, but most plentifully in Oxfordshire, whence it is continually sent up in great quantities to London. It makes, in its native state, a fine yellow, and, when burnt, a very beautiful red, and is the sort used for burning into red *ochre* in the colour-shops.

9. The *ochra argillacea, sordide flavescens*; the dull, dusky, yellow, clayey *ochre*. This is dug in Buckinghamshire, Staffordshire, and Oxfordshire, and is sent up to London, and used in the coarser mixtures at the colour-shops, in its native state, but, when rightly managed, it burns to a very fine valuable red. This, and the former, and some other of the before-mentioned, contain in them a considerable quantity of a genuine clay, and thence are more compact and stiff than the more pure kinds.

10. The *ochra argillacea, luteo-fusca levis*; the brownish, yellow, light, clayey *ochre*. This is common in Buckinghamshire, Northamptonshire, and many other counties, and though not so florid in its colour as many other *ochres*, yet makes a very pleasing paint, and has what the painters call a good body. This is not yet known among the painters, but is worth their being acquainted with. *Hill's* Hist. of Foss. p. 56.

11. The last is the *ochra ponderosa, friabilis, aureo-crocea*, commonly called *giallolino*, and by our painters *Naples yellow*. See the article GIALLOLINO.

The species of the red *ochres* are the following: 1. The *ochra rubra friabilis ponderosa, quæ sil Syricum antiquorum*; the red, heavy, friable *ochre*, the Syrian *sil* of the antients. See the article SIL.

2. The *ochra purpurea friabilis alkalina, quæ almagra recentiorum, sil Atticum antiquorum*; the friable, purple, alkaline *ochre*, the *almagra* of the moderns, and Attic *sil* of the antients. See the artcles SIL, and ALMAGRA.

These are both used at this time in painting, and the latter also in medicine. The first of them is common in many parts of England; the latter seems peculiar to Spain.

3. The *ochra purpurea ponderosissima dura*; the hard, heavy, purple *ochre*. This is well known among the painters, and called by them *Indian red*, and by Lemery *terra persica*. It is dug in the island of Ormuz, in the Persian gulph, and thence is dispersed over all the East-Indies. There is also some of it dug about Bombay. It is used both there, and with us, as a fine red in painting. *Hill's* Hist. of Foss. p. 58.

4. *Ochra friabilis floride rubescens*; the bright red, friable *ochre*. This is much esteemed in painting in many parts of the world, but is less known in England than in any other of the European nations. It is dug in vast quantities in the country above Bengall, and is used by the painters in France and Germany, as a fine red. It would be worthy our traders in these commodities better acquaintance. *Hill's* Hist. of Foss. p. 59.

5. The *ochra friabilis pallide rubescens, quæ bolus Veneta vulgo*; the pale red friable *ochre*, commonly called *Venetian bole*. See the article VENETA *bolus*.

6. The *ochra friabilis levis, pallide rubescens, alkalina*; the light, friable, alkaline, pale, red *ochre*. This is a very fine, and valuable earth, at present unknown in painting, but very easy to be had, and worthy the bringing into use. It is thrown up in digging in our American plantations, and proves, on tryal, to be a bright and fine colour in oil. *Hill's* Hist. of Foss. p. 60.

7. The *ochra argillacea pallidissime rubescens*; the pale red, clayey, *ochre*. This is a substance yet unknown to the world, but produced in great plenty in Pensylvania, and Virginia, and will, at least, supply to those countries all the purposes of the English reddle.

8. The *ochra purissima levis purpurascens*; the fine, light, purple *ochre*. This is a substance common in many parts of England, but not yet universally known among our painters. They often use it, indeed, without knowing what, or whence, it is; some considerable quantities of it having, at times, been sent to London, from the forest of Dean in Gloucestershire, and one or two of the colour-men engrossing it to themselves, and selling it, when prepared, under the name of *Indian red*, the third species of red *ochre*, to which it is, at least, equal in beauty of colour.

9. The *ochra purpurea ponderosa purissima, quæ rubrica sinopica antiquorum*; the fine, heavy, purple *ochre*, the *rubrica sinopica* of the antients. See SINOPICA *rubrica*.

10. The *Ochra argillacea indurata rubra, quæ Creta rubra auctorum*; the indurated, clayey *ochre*, called *red chalk*. See the article CHALK.

And the 11th, and last, the *ochra saxea rubra, quæ sil marmorosum antiquorum*; the red, stony *ochre*, the marbly *sil* of the antients. *Hill's* Hist. of Foss. p. 62. See the article SIL.

The species of brown *ochres* are only two; the first is, what the painters call *umber*; and the second what they call *Cologn earth*. See the articles UMBER, and COLOGN *earth*.

The blue, and green, are the substances called *lapis armenus*, and *bergruen*, which see under the articles ARMENUS *lapis*, and BERGRUEN.

Of the black *ochres* there are, lastly, two species; the first of these is the *ochra friabilis, ponderosa, nigrescens*; the heavy, friable, black *ochre*. A very fine, and valuable earth, worthy to be brought into use among the painters, though, at present, unknown to them. It is found in perpendicular fissures of the strata of stone in Leicestershire, and some other counties of England, and would make a very fine black, either in water, or oil. *Hill's* Hist. of Foss. p. 65.

The second is the *pseudo ochra levis, nigrescens, quæ Creta nigra pictorum*; the light, black, bastard *ochre*, called *black chalk*. See the article CHALK.

These are the several species of *ochres* at present known; and it is very plain, from this short account of them, that both our own country, and our plantations abroad, contain many treasures of them, the value of which is yet unknown.

Dr. Lister observes, that ochreous earths are separated in greater or less quantities, from all the medicinal springs of England, and it is to these, and the nitrous and muriatic salts, that they all owe their virtues. The *ochre* they contain is usually of the nature of that which our painters, to distinguish it from the yellower kind, call *brown ochre*. This is produced from the iron ores that are met with in the way of the current of

these

these waters; and, among the rest, the pyrites affords a great deal of them. All kinds of the pyrites, and all the lime-stones of England, when they are subject to be much moistened under ground, will, in time shoot out their salts, and part with their earths. *Lister* de Font Med. Angl.

The earth of the pyrites is *ochre*, and the salt of the lime-stone is the calcarious nitre, an alkaline salt of the nature of the natrum of Ægypt; and from these two substances, and a small portion of common salt, which the waters take up in their passage through the earths that contain it, all the virtues of them are owing. The salt of the pyrites being green vitriol, it might be expected that this should be found in the waters impregnated by that substance; but Dr. Lister observes that though there are many springs in England which are well known to receive their virtues from this fossile, yet there is no such thing as vitriol to be obtained from any of them; and this is not wonderful, since we know that the pyrites will not yield its vitriol when newly taken out of the earth, but must be exposed a considerable time first to the air; so that the *ochre* only is the sensible thing that it receives from this substance, and, perhaps, with it some saline matter which is the basis of vitriol, and would be vitriol in time, on a due exposition to the air.

OCHROPUS *gallinula*, in zoology, a name by which many authors have called a bird more usually known by the name of *tringa*. *Gesner* de Avib. See the article TRINGA.

OCHROPUS, or *gallinula* OCHROPUS, the *yellow-legg'd moorhen*, a species of the *gallinula*, or *moorhen*. It is of the size of the common kind; its beak, as well as its legs, is yellow, or of a sulphur colour; its back is of a redish brown; the tips of its wings of a very fine red; it has white variegations on its head, and in the middle of its wings, and on its belly; the longest feathers of its wings are black; and there are also spots of black on the back in several places. The edges of its eye-brows are of a deep saffron colour; and it has, beside all these colours, a great deal of grey in the wings. It has no hinder toe. It builds in thickets, in watery places, among rushes and high grass. *Aldrovand.* de Avibus, l. 20. c. 48 *Gesner* de Avib.

OCHRUS, in botany, the name of a genus of plants, the characters of which are these. The flower is of the papilionaceous kind. The pistil arises from the cup, and finally becomes a pod, which is usually of a rounded, or cylindric form, and contains a number of roundish seeds. To this it is to be added, that the leaves are sometimes single, sometimes of the conjugated kind, and terminating in tendrils.

The species of *ochrus* enumerated by Mr. Tournefort, are these: 1. The *ochrus* with undivided leaves, sending out tendrils from their ends, and with yellowish seeds, called *ervillia* by some authors. 2. The *ochrus* with undivided leaves, terminated by tendrils with brown seeds. 3. The *ochrus* with undivided leaves terminated by tendrils, with black seeds. And 4. The yellow-flowered, woolly, American *ochrus*. *Tourn.* Inst. p. 396.

OCIMUM, in botany. See OCYMUM.

OCNUS, in zoology, a name by which Aristotle, and other of the antients have called the *bittern*, or *butter bump*. See the article BITTERN.

OCOB, a name given by some chemists to *sal armoniac.*

OCREA, (*Cycl.*) among the antients, a kind of military shoe, or short boot, which was made of white tin, and ornamented with gold, or silver, about the ankles. Its use was very antient, the Greeks were so well provided with them in Homer's time, that he thence gives them the appellation of ἐυκνήμιδες Ἀχαιοὶ. Among the Romans, none were allowed to wear the *ocreæ*, but the two upper classes of the people, or such whose estate exceeded 7500 drachms. See *Hofm.* Lex. Univ. in voc.

OCTAETERIS, Ὀκταετηρὶς, in antiquity, a cycle, or term, of eight years, at the end of which three entire lunar months were added This cycle was in use till Meton, the Athenian, reformed the calendar, by finding out the golden number, or cycle of nineteen years. *Potter*, Archæol. Græc. T. 1. p. 460. See CYCLE, and CALENDAR, *Cycl.*

OCTANDRIA, in botany, a class of plants with hermaphrodite flowers, and eight stamina, or male parts in each. See Tab. 1. of Botany, Class 1.

The word is formed of the Greek ὀκτὼ eight, and ἀνὴρ male. The plants of this class are the maple tree, heath, &c.

OCTAVE (*Cycl.*) — *Diminished* OCTAVE, in music. See DIMINISHED *octave*.

OCTAVINA, in the Italian music, a kind of small spinnet, easily moved, having only one row of keys, and those not to the usual number, perhaps not to above three octaves, the common ones going to four, or more. See SPINET, *Cycl.*

OCTOPHORUM, among the antients, a carriage with eight wheels.

It also signified a chair, or litter, *lectica*, carried by eight chair-men, which kind of chair was mostly used by the women. *Pitisc.* in voc.

OCTUNX, a word used by some dispensatory writers to signify eight ounces.

OCULATA, in zoology, a name given by many to the fish more usually called *melanurus*. It has the name *oculata* from the remarkable largeness, and fine golden iris of its eyes. *Willughby's* Hist. Pisc. p. 310. See MELANURUS.

OCULATUS *lapis*, the *eyed stone*, a name given by Mercatus, in his Metallotheca Vaticana, and by many other writers, to what we call the *pudding stone*, a stone formed of a great number of pebbles, of a small size, immersed, and formerly bedded, in a flinty cement, little less hard than the stones themselves, and in some species not at all so. The resemblance of these round pebbles, when the mass was cut, to the eyes of animals, probably gave origin to this name. It is easy to conceive that at the time when these stones were formed the matter of the cement was soft as mud, while the stones which are bedded in it were hard, and perfectly formed, otherwise they could never have had admission into it. It is also natural to suppose, that as these stones are placed very irregularly in the mass, the ends and sides of many of them must be prominent above the rest, and above the surface of the cement; and this we usually find to be the case: but in some places we find large lumps of this stone, whose surfaces are naturally smooth, as if wrought by art; the external pebbles being thus cut off, as it were, down to the level of the surface, and their internal lineations appearing. We find several stones rounded and smoothed on the surface in this manner, by long lying on the shores of the sea, and being there washed about among other hard bodies by the tides. But these masses are also found in gravel pits, and those such as have evidently been so ever since the formation of the crust of the earth after the deluge, and have never been disturbed, or removed, since that time. As a hurry, and violent motion of the water, alone can have occasioned the wearing down of these pebbles on the surface of the *pudding stone*, and as they have never been in the way of such a motion of water since the time of their subsiding from among the waters of the deluge, it must have been at that time that they were thus rolled about, and rounded; and this is one great proof of the Woodwardian system of things at that time; and that the waters, in departing from off the surface of the earth, ran with great violence, and carried stones, &c. a long way in their current, in which course they suffered all that the dashing, and rolling about in the waters of the sea, could do to such stones in a long period of time. See Tab. of Fossils, Class 5. *Mercati* Metall. Vat. p. 139. *Woodw.* Cat. Foss. Vol. 1. p. 46.

This *pudding stone* is not the only instance of this effect of the rapidity of the waters of the deluge in running off from the face of the earth, for there are found in many places great numbers of stones which have been parts of strata, or larger masses, and which have been broken off, and rolled into the form of pebbles at that time. And among what we commonly understand by the name pebbles, we find many which have prominent ridges running round them, which have been veins harder in their matter than the rest of the stone; and therefore, while the rest has been worn away, these have remained less worn, and consequently standing higher than the other parts.

OCULIPETA, in zoology, a species of serpents. See the article TEXMINANI.

OCULUM *aperiens*, in anatomy, a name given by several authors to a muscle of the face, called by the generality of writers *aperiens palpebram*, and *aperiens palpebram rectus*; by Albinus, *levator palpebræ superioris*.

OCULUS *beli*, in natural history, the name of one of the semi-pellucid gems of the genus of the *hydrophanæ*, and called by Dr. Hill *hydrophanes albido-cinereus, flavo-variegatus, nucleo centrali nigerrimo*, or the greyish white *hydrophanes*, variegated with yellow, and with a black, central, nucleus. See Tab. of Fossils, Class 5.

It is a very elegant, and beautiful gem. Its basis, or ground, is a whitish grey, variegated with yellow, and sometimes with red, and a little black, but that more rarely, and is found in small masses from half an inch to an inch in diameter; of a rounded figure, and thickest in the middle, tapering away gradually to the sides. The outer part of the stone, or that toward the edges all round, is ever of a whitish grey, more or less variegated with yellow, &c. and its central nucleus is always of a deep and fine black, surrounded by a broad circle, of a pale yellow, and representing very beautifully the pupil and iris of the eye; these are enclosed in the matter of the stone, and are often surrounded by other very fine concentric circles, of a pale flame colour; but more frequently there is only the black pupil, surrounded by the yellow iris, and that placed in the body of the stone which represents the white of the eye: the shape of the stone also favours its resemblance of an eye, and the whole is very elegant. It is of the hardness of the agate, and takes a tolerable polish; when thrown into water, it has, in a great measure, the property of the oculus mundi, the whole stone becomes greatly more bright, and lucid, and the grey part becomes of a plainly yellowish cast.

There are many things improperly called *oculus beli* by our jewellers, but the genuine species is very rare. Nothing is more common than to find in the agates little circular veins of different colours round a central spot; these the lapidaries frequently cut out, with a proper quantity of the stone about them, and call them *oculus beli*. They are not peculiar to the agate, but are common also in the cornelian, and stand sometimes,

times single, sometimes two or three together, and according to the colours of the circles, represent the eyes of various animals. *Hill's* Hist. of Foss. p. 470.

OCULUS *cati*. See the article ASTERIA.

OCULUS *leporinus*, a distemperature of the eyes, called also *ectropium*. *Heister's* Surgery, p. 432. See ECTROPIUM.

OCULUS *marinus*, the *sea eye*, a name given by some authors to the *umbilicus marinus*, from its resemblance to the shape of an eye. See UMBILICUS *marinus*.

OCULUS *mundi*, in natural history, the name of one of the semi-pellucid gems of the genus of the *hydrophanæ*. It is of one plain and uniform colour, which is a whitish grey, and has no veins, or other variegations. It is found in small masses, of the shape of our common flints, and pebbles. It has but a very obscure degree of transparence, and is not capable of a fine polish. This stone, however, though of little beauty, has this very singular property, that, when thrown into a bason of water, in the space of half a minute, it begins to change its appearance, and, very soon, instead of a pale grey, becomes of a very bright, and considerably pellucid, pale yellow, like that of amber, or the yellow cornelian; this it retains as long as it remains in the water, but as soon as taken out, and dried, it resumes its grey colour, and becomes as opake as before. It is found so far as is yet known, only in China; but the shores of some of our own rivers afford us stones coming up to its qualities in some degree, though not so beautifully transparent in water as the oriental. *Hill's* Hist. of Foss. p. 468.

OCULUS *Veneris*, a name given by some to the *umbilicus marinus*.

OCYMOPHYLLON, in botany a name given by Buxbaum to a new genus of plants, the characters of which are these: the flower is of the staminenous kind, having no petals; this stands upon the embryo fruit, which afterwards becomes an oblong quadrangular seed vessel, divided into four cells, and containing roundish, and very small, seeds. Its leaves are like those of the common ocymum, or basil, whence its name; and its place of growth is in damp marshes. Boccone has described it under the improper name of *glaux*, calling it the great, green-flowered, *marsh glaux*. Act. Petropol. Vol. 4. p. 421.

OCYMUM, *basil*, in botany, the name of a genus of plants, the characters of which are these. The flower consists of one leaf, and is of the labiated kind. The upper lip is erect, roundish, and crenated, and is larger than the under one, which is curled up, and lightly indented. The pistil arises from the cup, and is fixed, in the manner of a nail, to the hinder part of the flower, and surrounded by four embryos, which afterwards become as many seeds, of an oblong figure, to which the cup of the flower serves as a capsule. This cup is divided into two lips, the upper of which is erect and bifid, and the other divided into several segments, by slight notches.

The species of *basil* enumerated by Mr. Tournefort are these: 1. The clove *basil*, or *acinos*, of Columna. 2. The great *basil*, with fimbriated leaves, resembling those of endive. 3. The broad-leaved, spotted, and curled *basil*. 4. The green *basil*, with bullated leaves. 5. The green leaved, fimbriated *basil*. 6. The common large clove *basil*. 7. The largest clove *basil*. 8. The large black *basil*, with a strong smell of rue. 9. The citron-scented *basil*. 10. The anise-scented *basil*. 11. The common, or middle *basil*. 12. The white-flowered, common *basil*, with deep, blackish green, leaves. 13. The blue-flowered, common *basil*, with deep, blackish-green leaves. 14. The middle-sized, curled *basil*, with a short, conglomerated spike. 14. The small, serrated, narrow-leaved *basil*. 16. The small, narrow-leaved *basil*, with bullated leaves. 17. The three coloured *basil*. 18. The smallest *basil*. 19. The least *basil*, with purplish black leaves. *Tourn.* Inst. p. 203.

OECOMENIUM, in botany, a name given by the antient Greeks to a plant called also *thapsia*, and *cymene*. See THAPSIA and CYMENE.

OECONOMICAL *chemistry*. See CHEMISTRY.

OEDEMA (*Cycl.*) — The persons most subject to *œdematous* tumors, are people of a phlegmatic habit, and such as have had suppressions of some natural evacuations. Men who have had the hæmorrhoidal discharges stopped upon them, and women labouring under suppressions of the menses, are more than all others subject to them. Persons somewhat advanced in age, are, in general, more subject than young ones, and women with child, particularly during the more advanced state of their pregnancy, are often afflicted with them. The long holding the legs in cold water, will sometimes alone occasion them, and, among the poorer country people, the women who make a custom of standing in the water to wash their cloaths are often affected with these swellings in one or both knees. People who have received large wounds, and have had them treated rashly, with cold applications, are also sometimes thrown into danger of these swellings. The repelling tumors of other kinds, and sometimes the striking in an erisipelas, or other cutaneous eruption, will also occasion them; and sometimes people who have been treated with too hot a regimen in acute fevers are subject to swellings in their feet, which though they appear red, and are hot at times, yet, when strictly examined, appear to be truly *œdematous*.

Prognostics in this case. *Oedematous* swellings are always very obstinate, and tedious in their cure; but they are the more so when their causes are the more complicated, and more things than one conspire to their origin. None of these swellings are so easily cured, as those which arise from external injuries, or simple refrigeration; and those which arise from cutaneous humors struck in, are often found very easy of cure, provided that they are not of very long standing: and, in general, such as are very cold when out of bed, and always very hot when in it, are more difficult of cure than others. But this is to be observed, that there is great difference between a cure of these tumors, and the only striking them in; the latter case being very often attended with much worse complaints than the tumors themselves, the too frequent consequences of such retropulsions being inflammations of the abdomen, and præcordia, and absolute dropsies.

Method of cure. The first step towards a cure must be the correcting the mucous and viscid state of the humors: this is best done by the neutral salts, as tartarum vitriolatum, and the like; and by gum ammoniacum, the roots of pimpernel, and woods of sassafras, guaiacum, and the like, with the warm aromatics, as ginger, and the spices, and carminative seeds. The matter, when thus attenuated, is to be evacuated by purges of a strength proportioned to the constitution of the patient, and, after this, the true tone of the parts is to be re-establish-ed by chalybeates, and the part to be secured from a relapse with a large bandage, and with warm and strengthening fomentations. It rarely happens that these swellings ulcerate, but when they do, there is no application so proper as the liquor of myrrh. *Junker's* Consp. Med. p. 410.

The method of treating *œdematous* tumors is very different according to the different causes to which they owe their rise. The external method of treating these tumors in the legs and feet is usually to have recourse to frequent frictions with warm cloths; these are to be repeated every night and morning, and the parts to be rubbed each time till they appear very red, and are hot; the limb is then carefully to be preserved from the injuries of the cold air, and it is a very proper method to wear stockings made of some warm furr, and to lie with hot bricks, wrapped up in cloths, near the legs and feet, to divide, and attenuate the blood: a proper bandage is, after these methods, to be applied, which is to ascend gradually from the feet up to the knees; this strengthens the limb, and prevents a stagnation, and collection, of the blood in any part of it. Proper strengthening internal medicines must be given during all this time; and, after the trying what has been already directed, strengthening remedies are to be attempted externally also: to this end the limb may be placed over burning rectified spirit of wine, wrapping it up in cloths in such manner that it may receive the steam; this will encline the stagnating fluids to escape through the skin, or else render them fit to return into the circulation, and at the same time will do much toward restoring the proper tone of the limb. In many families it is a secret to apply the herb great celandine, bruised in manner of a pultice, either alone, or mixed with the persicaria acris or water pepper, and great benefit is sometimes obtained by these herbs, for they are very active medicines, and powerful resolvents. Others apply also for the same purpose, the lepidium, or pepper-wort, and horse-radish root, scraped, and moistened with white wine; but the most excellent remedy of this kind is the cataplasm made of pidgeon's dung, mixt with common salt and vinegar, and applied warm, and often removed. A fomentation of no small use is made also of a lee made of oak ashes, mixed with smith's forge water, adding a little spirit of wine, and a small quantity of alum. This may be applied with stuphs or the legs may be bathed in the liquor, as warm as it can well be borne, twice a day. Spirit of wine also, either alone, or mixed with lime water and alum, or lime water alone, are good fomentations; and another from which great benefit has been received is this: take spirit of wine, and common vinegar, of each a pint; crude alum an ounce and half; vitriol an ounce; mix all together, and use it as the foregoing. Great care must always be taken after the using these, or the like fomentations, that the limb be well covered with bandages and stockings; the patient must also, during the time, drink sparingly, and use moderate exercise frequently. The medicinal waters, especially the sulphureous, often do service in these cases, but they do not always succeed. Dr. Harris relates, that he has cured the most dangerous of these cases, with a mixture of the aperient saffron of steel, and the bark. Others speak of having performed cures with the bark alone; but there are not wanting some who declare this to be a very dangerous method. *Heister's* Surgery. p. 232.

OEDICNEMUS, in zoology, the name of a bird called also *charadrius* by Gesner and Aldrovand, and in English the *stone curlew*. It is a considerably large bird, weighing eighteen ounces. Its beak is about two fingers breadth long, and is strait, pointed at the end, and partly black, partly yellow. It has a naked, yellowish, green membrane under its eyes; its legs are long, and yellow; and it has only three toes, having no hinder one. Its thighs are naked half the way up, as

in other water birds. Its breast and thighs are white. Its throat, back, and neck, of a mixture of reddish brown and black, much like the colour of the curlew; whence the English have very improperly called it the *stone curlew*. The under part of its tail is reddish. It breeds very late, the young being often found callow at the latter end of October. It lives principally in watery places, and flies in the night, making at that time a very remarkable shrill noise. *Ray's* Ornithol. p. 227.

OENANTHE, *water dropwort*, in botany, the name of a genus of umbelliferous plants, the characters of which are these: the flower is of the rosaceous kind, composed of several heart-shaped petals, which are irregular in size, and are disposed in a circular form, on a cup, which afterwards becomes a fruit composed of two oblong gibbose striated seeds, which are flatted and smooth on their inner side, and end in a sort of prickles, the middle one of which is longer and stronger than the others. The species of *œnanthe* enumerated by Mr. Tournefort, are these. 1. The parsley-leaved *œnanthe*. 2. The sea *œnanthe*, with blackish-coloured, parsley-like leaves. 3. The Portugal *œnanthe*, with the leaf and the smell of parsley. 4. The chervill like *œnanthe*, or poisonous, hemlock *dropwort*. 5. The staphylinus-leaved *œnanthe*. 6. The common water *œnanthe*. 7. The rue-leaved, water *œnanthe*. 8. The proliferous, water *œnanthe*. 9. The *œnanthe* with black and long roots. And, 10. The Portugal *œnanthe*, with a thick globose seed. *Tourn.* Inst p. 312.

One of the species of this plant, distinguished by its yellow juice, and by its growing near waters, is a very terrible poison. Many accounts have been given of people dying by it, but none which sets its terrible effects in so just a light, as one which happened very lately to some French prisoners with us, and which is recorded in the Philosophical Transactions. Eleven French prisoners had the liberty of walking in, and about, the town of Pembroke; three of them being in the fields a little before noon, found, and dug up, a large quantity of this fatal plant, with its roots, taking it to be wild celeri, in order to eat it with their bread and butter, after dinner; and, when they had washed it, they all three tasted, or eat a small quantity of it, in the fields.

As they were entering the town, one of them, without any previous notice of sickness at the stomach, or disorder in the head, was immediately seized with convulsions; the other two ran home, and sent a surgeon to him, who attempted to relieve him by bleeding, but in vain, for he died in a very little time. The other two prisoners, wholly ignorant of the cause of their comrade's death, and of their own danger, gave the roots they had brought in to the other eight prisoners, who all eat more or less of them with their dinner. A little while after dinner, the two remaining persons who had gathered the roots, were seized in the same manner as the first, and one of them died, but the other recovered, having been blooded, and a vomit having been, with great difficulty, forced down his throat, as his jaws were, in a manner locked together. The other eight were all immediataly bled, and vomited, and all recovered.

It is observable that none of these persons had those comatose symptoms which are well known to attend those who have eaten the common cicuta, or hemlock.

This root is well known in all that part of England under the name of the *five-fingered root*, and is in frequent use externally with the common people, for the felon, or worst sort of whitloe. The Frenchmen eat only the root, and none of the leaves, or stalk.

It is extremely necessary that this dangerous plant should be well known, as it grows very plentifully with us all about the banks of the Thames; and Mr. Watson has caused a fine drawing, both of this, and of another poisonous plant which it is often confounded with, the cicuta aquatica, or water hemlock of Wepfer, to be prefixed to that number of the transactions where this account is given: and this seems the more necessary, as the plant seems to have been mistaken in a manner by all the world, not only the common people, but the more versed in plants, having mistaken it at times for several very different things. The same gentleman informs us from various authors, that eight lads in Ireland had been poisoned by it, mistaking it for the root of the water parsnip; two men died by mistaking it for the Macedonian parsley; and Wepfer, who wrote an exprefs treatise on the poisonous nature of the water hemlock, has confounded this plant with it, saying, that Lobel had described the water hemlock, under the name of this *œnanthe*, or *dropwort*; and the generally accurate Hoffman, when treating of the vegetable poisons, makes no mention of the difference between these two plants.

Neither the roots of this *œnanthe*, or those of the cicuta aquatica, or water hemlock of Wepfer, have any disagreeable flavour to deter those who taste of them from eating, and they both occasion violent convulsions, and death, if not timely prevented. The intention of cure seems in both the same; first by emptying the stomach and intestines as soon as possible, and then causing the patient to drink largely of oleaginous fluids; there is great difficulty, however, of getting the patient to swallow any thing, the jaws being fastened together by the spasm; after the stomach has been freed from this pernicious vegetable, the symptoms have generally abated by degrees, and the patient has recovered.

Threlkeld mentions this plant as growing in Cumberland, where the people call it *dead tongue*, and use it as a pultice to the galled backs of their horses. The German botanists do not mention it as growing among them, nor Haller in his *Enumeratio stirpium Helvetiæ*, whence it seems to be seldom met with, except in England, Holland, and some parts of France. Phil. Transf. N° 481.

OENANTHE, or *dropwort*, in botany, is also a name originally given by the antient Greeks to the flowers of the wild vine. It was afterwards made to express also the flowers of the common manured vine, and the young grapes while small, and just appearing from the flowers. These, with the tendrils, and small leaves of the vines, were sometimes used for the making garlands, and ornamenting other things; and after this, another plant of a very different nature became used on the same occasions, and called by the same name.

Pliny supposes that the umbelliferous plant *œnanthe*, was so called from its flowers having the smell of grapes; but we find this to be a mere imaginary notion, for Meander, and many other of the Greek writers, declare the flowers of the *œnanthe* to have no smell at all; but suppose that they were called *œnanthe* from their growing in clusters like those of the vine.

The herb *œnanthe* became famous in the ointments of the Greeks, which were intended to rub the body with, to give strength, and to take off lassitude, or weariness. Many have doubted whether the *œnanthe* used in these compositions was the flower of the vine, or the plant *œnanthe*; but Theophrastus clearly decides this in favour of the plant, and says, that not only the flowers, but the leaves of it, were used for this purpose; but then he distinguishes the plant into two kinds. His account is, that the Cyprian *œnanthe* was very sweet-scented, and grew upon the mountains, and in other dry and barren places; and that the *œnanthine* ointment was made with its leaves and flowers, but that this could not be made with the Grecian *œnanthe*, because that had no smell. Dioscorides runs counter to this; and says, that the *œnanthine* ointment was made of the flowers of the wild vine, and that that was always esteemed the best which smelt most strongly of the flowers of that shrub. It appears therefore that there were two different ointments of this name in use among the Greeks.

Pliny, that he may lose nothing in his description of the *œnanthe*, copies both Theophrastus and Dioscorides in their accounts of this plant; and, in consequence, has put together a wholly confused, and unintelligible relation of the nature and virtues of this plant.

OENANTHE, in zoology, the name of a genus of birds of the smaller size, of which there are four species: 1. The common *œnanthe*, called the *fallow-finch*, or *wheat ear*. 2. The *œnanthe* called *anthus*, and *florus*; and in English, the *whinchat*. 3. The *œnanthe* called *rubetra*, and in English the *stone-chatter*, or *moortitling*. 4. The American *œnanthe*, or *guirarhu nheengeta*. *Ray's* Ornithol. p. 169, 170. See the articles WHEATEAR, WHINCHAT, &c.

OENARIA, a name given by the antients to ashes prepared from the leaves, tendrils, and young stalks of the vine. They were accounted highly diuretic.

OENOGALA, a word used by Hippocrates, and other of the Greek authors to express a mixture of milk and wine for immediate drinking. Others have used it to express wine alone heated, so as to be just as warm as new milk.

OENOMANTIA, Οινομαντεια, in antiquity, a species of divination by wine, which is done by making conjectures from the colour, motion, noise, and other accidents of the wine of libations. *Potter*, Archæol. T. 1. p. 319.

OENOS, in zoology, the name used by authors for the *stock-dove*, or *wood pigeon*, called also by some *vinago*, somewhat larger than the common pigeon, but of the same shape and general colour. Its neck is of a fine changeable hue, as differently opposed to the light; and its breast, shoulders, and wings are of a fine purplish hue, or red wine colour, from whence it has its name *vinago*. Its legs are red, and feathered a little below the joint. *Ray's* Ornithol. p. 136.

OENOSTAGMA, a name given by some of the chemical writers to *spirit of wine*.

OEPATA, in botany, a name by which some authors have called the tree which produces the fruit called *anacardium orientale*, or the Malacca bean. Hort. Mal. Vol. 4. p. 95.

OESTROMANIA, a name given by some authors to the uterine disorders which sometimes affect young women, and is commonly called *furor uterinus*.

OESTRUM (*Cycl.*) — OESTRUM, in zoology, the name of a species of fly, called also sometimes the *gad-fly*, *breeze-fly*, and *asylum*. It is a very troublesome creature to oxen, but is not so common as some suppose. It is never found, except in the neighbourhood of waters: the head is green; the body yellowish; the eyes are very large; and the trunk long, and remarkably strong. It flies very swiftly, and without noise. Mouffet mentions, beside our English kind, two others, the one from Virginia, the other from Muscovy; the first very large, having a great head, and a white streak down the shoulders; the latter remarkable for having wings of a silvery colour, reaching beyond the body.

OESTUM *Veneris*, a name given by some anatomical authors to the *clitoris*.

OETHODES *ulcus*, a term used by the Greek writers for such ulcers as had tumid, and callous lips; and as such ulcers are usually very difficult to heal, the word became afterwards appropriated to all sorts of ulcers difficult to cure.

OFF-*set-staff*, in surveying, a rod, or staff, of any convenient length; for instance, of 10 links of the chain. This staff is divided into 10 equal parts. Its use is for the ready measuring the distances from the station line of things proper to be represented in a plan. See CHAIN.

OFF-*ward*, in the sea language, the same with contrary to the shore; thus they say, *the ship heels off-ward*, when, being aground, she heels towards the water side; *the ship lies with her stern to the off-ward, and head to the shore-ward*, when her stern is towards the sea, and head to the shore.

OFFA *alba*, (*Cycl.*) in chemistry, a concretion produced by a due mixture of spirit of urine, or spirit of sal armoniac with the spirit of wine. Some call it the *offa alba* of Paracelsus [a], others of Van Helmont, whence it is sometimes called *offa Helmontiana*; but Van Helmont was not the inventor of it, but Raim. Lully, says [b] Boerhaave.

The manner of making the *offa alba* is described in this last author [c], who observes it to be difficult, as it requires both liquors to be perfect, and some nice circumstances to be observed. — [[a] *Boyle's* Works, abridg. Vol. 1. p. 32. [b] *Boerh.* Chem. Vol. 2. proc. 122. [c] Id. ibid.]

Van Helmont [a] endeavours to account for the formation of the stone in the bladder, from this experiment; but, as Boerhaave [b] observes, the *offa alba* has nothing in common with the stone. — [[a] *Boyle*, loc. cit. [b] Ibid.]

Boerhaave recommends this mixture as a good deobstruent, taken in Canary fasting. Ibid.

OFFENCE, *delictum*, in law, an act committed against the law, or omitted where the law requires it. *West*, Symbol.

Offences are distinguished into two kinds, viz. such as are capital, and such as are not. Capital *offences* are those for which the offender is to lose his life. Those not capital, where the offender may forfeit his lands, and goods; be fined, or suffer corporal punishment, or both, but not lose his life. *Hale*, P. C. 2. 126, 134. Under capital offences are comprehended high treason, petit treason, and felony: and offences not capital include the remaining part of the pleas of the crown, and come under the title of misdemeanours.

Some *offences* are punishable by the common law, but most of them by statutes.

OFFICIARIIS *non faciendis, vel amovendis*, a writ directed to the magistrates of a corporation, requiring them not to make such a man an *officer*, or to put one out of the *office* he hath, until enquiry is made of his manners, &c. Reg. Orig. 126. *Blount*, *Cowel*.

OFFION, a name used by some of the medical writers for *opium*.

OIL (*Cycl.*) — The use of *oil* in stopping the violent ebullition of various substances, may be very great in many occasions of life. It is well known that if a mixture of sugar, honey, or the like, be boiling on the fire, and in danger of rising over the sides of the vessel, the pouring in a little *oil* immediately makes it subside. In many cases the marking a circle round the inside of a vessel, in which a liquor of this kind is to be boiled, with a piece of hard soap, shall, like a magic ring, confine the ebullition to that height, and not suffer it to stir any farther. This is wholly owing to the *oil*, or fat contained in the soap: but there is, beside these, another very important use of *oil*, on a like occasion, which is the pouring a little of it on any metallic solution, while making; this restrains the ascent of the noxious vapours; preserves the operator from danger; and, at the same time, by keeping down the evaporating matter, gives redoubled strength to the menstruum.

Animal OIL, *oleum animale*, in medicine, the name of an essential *oil* distilled by a retort from blood, and recommended as a powerful remedy in epilepsies, the gout, and other obstinate diseases.

It was originally used in Germany in these intentions, and has become of late much used in England, but should not be given too freely as an internal. As an external, it may probably be of good service in removing fixed pains, removing hard tumors, &c. for it is extremely penetrating. *Shaw's* Lectures, p. 147.

OIL *of camphor*, a name given by the chemists to a solution of camphor in spirit of nitre. It is used to exfoliate carious bones, and on other the like occasions It is observable, that camphor, which is soluble in this acid, in the proportion of one half its quantity, is not at all soluble in spirit of vitriol, spirit of alum, or distilled vinegar; and that it is the only known vegetable resin that is soluble in this menstruum. See CAMPHOR.

Chemical OILS, a name given by some to the essential *oils* of plants, and other substances separated in distillation, and swimming on the surface of the water, where the alembic is employed. They are distinguished by this title from the expressed *oils*, such as those of almonds, linseed, olives, and the like, which are made by so simple a process as mere squeezing. See *essential* OILS, infra.

To procure this chemical principle pure and unmixed from the matter distilled from a vegetable body, the unctuous matter obtained from the process, may be washed from its adhering salts, and grosser earth, in warm water, barely by shaking them in a glass together, then separating the *oil* from the water by means of the common separating glass; in which, if the *oil* be specifically heavier than the water, it sinks to the bottom, and may be suffered to run out first, by means of the pipe of that glass which has its insertion at the bottom; if specifically lighter than the water, it may be kept behind, as it floats on the top of the water, while all that is poured off, and has carried the gross fæculent parts with it. *Shaw's* Lectures, p. 150.

Connecting OIL, in chemistry, a term used by Boerhaave, and his followers, to express a certain *oil*, found in all vegetable substances, but wholly differing from, and independent of, their essential *oil*. This is not possessed of any of their virtues, or qualities, but seems the same in all plants, and is the means of their consistence and solidity, giving tenacity to their earth, which, without it, falls to dust, and the plant exists no more.

This *oil* is not separable by boiling water, as the essential *oil* is, but only by fire: when a plant has been boiled, and distilled, its essential *oil*, salt, &c. are all carried off, and what remains is only the earth connected by this *oil*. This being exposed to the fire, the *oil* discovers itself in a thick, black, stinking smoak, and finally, taking fire, it burns away, and leaves only the earth which was the basis of the plant, retaining its form, indeed, if the process have been carefully made, but falling into a shapeless powder only on being roughly breathed upon.

This great author, therefore, establishes it as a rule, that there are three sorts of *oils* in plants. 1. An *oily* froth. 2. The *essential oil*, dissolved in decoction. And, 3. This *connecting*, or *consolidating oil*, separable only by a naked fire. *Boer.* Chem. Part 2. p. 20.

Essential OIL. There is found in every plant analysed by distillation, an *essential oil*; but this is very different from the same plant, both in its quantity and in its qualities, as it is managed in the operation.

If a plant be thrown into a retort, and distilled with a violent fire, it is known to yield less *oil*, than if the fire were more moderate: if the plant be fermented, especially if it be of the aromatic kind, it always yields much more *oil* after this operation, than it does without it.

It is plain from hence, that there are methods of obtaining more *oil* from the same plant, than would be yielded by it in the common way; and it is as certain, that according to all the methods in common use, there is ever left a large quantity of the *oil* behind; and therefore, that a way may possibly be invented of drawing yet more from the same plant than is yet known to be done. We all know, that when the residuum in the retort, after the distillation of the plant, is burnt in the open air, it loses half, or often three fourths of its weight, and the matter evaporated in this burning to cause this great diminution can be only the remainder of the *oil* of the plant, which would not be separated from its earth in a close vessel.

It may be observed also, that the *oil* of a plant, in the distillation by the retort, never comes over till toward the end of the process, and drops from the neck of the vessel at the same time with the acid spirit of the plant, and while the urinous volatile salt is also rising; so that the three principles are, in a manner, all separated from the plant together: when there is a large portion of acidity in the plant, and but a small quantity of urinous salt, it is also constantly observed, that there is a larger quantity of *oil*, and that this *oil* is more fluid, and that the caput mortuum diminishes less in burning. This particular is remarkably observable in the analyses of mallows, prunella, melilot, and southernwood. On the contrary, such plants as yield but a small quantity of acid spirit, or volatile salt, always afford but little *oil*, and that *oil* is always thick, and the caput mortuum of these plants diminishes greatly in burning; that is, a great quantity of the *oil* was entangled in the earthy matter, and could not get loose, otherwise than by burning the plant in the open air. Instances of this sort are found in the analyses of the *caltha palustris*, &c.

Hence it appears, that the acid and volatile salt in plants are greatly instrumental to the disengaging their *oil*, and giving it separate in distillation Hence when a plant does not contain acid enough in itself to disengage its *oil*, it appears no ill method to try to assist the separation by the addition of another acid of the vegetable kind.

To try this, Mr. Homberg first distilled a certain quantity of fennel-seed in the common way, and afterwards distilled the same quantity of the same seed, in the same manner, except that he added for every pound of the seed four ounces of spirit of salt to the water in which it was put for distillation This last distillation yielded one third more *oil* than the first Both the *oils* were equally clear, and strong-scented of the seeds, but the last seemed to smell less of the fire than that obtained by the simple distillation in the common way. There is no doubt but that the spirit

rit of falt in this procefs not only encreafed the natural ferment in the liquor, which is neceffary to the feparation of the *oil*, but that it alfo attenuated the particles of the *oil* in the feed, and made them much more eafily feparate themfelves, and rife with the heat, than they would otherwife have done. What not a little confirms this opinion alfo, is the known experiment of rendering camphor liquid by means of acid fpirits. Mem. Acad. Par. 1700.

The modern chemifts have not looked upon the *oil* as one of the genuine principles of the plant it is drawn from, as has been the cuftom among writers of earlier date. They know that thefe *oils* are themfelves mixed bodies, and capable of another analyfis, by which they are feparated into falt, phlegm, and earth. Thefe three principles conftitute all *oils*; but thefe differ greatly in different plants, and that perhaps, more from their manner of admixture than from their different quantities. That bodies of the fame kinds, varioufly mixed, may have thefe different appearances, is in nothing more evident, than in the mixture of quickfilver, and fulphur; if this be done only by grinding, the refult is a black powder; but, if they are fublimed together, they form a red, bright, compact body, formed of feveral congeries of ftriæ, called cinnabar. And, in the fame manner, the fame principles, phlegm, falt, and earth, may, according to the different manner of their mixture, form *oils* of very different natures one from another: nor is this all the fource of their difference, for, by our own management of them, we make them appear in very different forms, in the fame fpecies. Thus the *oil* naturally contained in a feed is produced from it, according to our different management, in three different forms. To inftance this: in the *oil* of anifeed if we heat and prefs this feed, we draw what is called an *oil* by expreffion, a fattifh fubftance, of the nature of *oil* of olives, almonds, and the like, and with only a moderately acrid tafte; if we diftil it with water in an alembic, we obtain the *effential oil*, or common *oil* of anifeed; and if we diftil it dry by the retort, we obtain a fetid, thick, and empyreumatic *oil*. The *oil* in the feed is evidently the fame, but it puts on thefe forms according to our pleafure. Mem. Acad. Par. 1707.

Expreffed oils, as well as balfams, and refins, when applied to the animal bodies, increafe putrefaction, and are the moft effectual fuppurants and incarners. *Monro*, in Med. Eff. Ed. Vol. 5. Art. 24.

It may be eafily feen from this, that little knowledge of the nature of the *oils* of plants is to be obtained from the common analyfes; the way to truly underftand them, is to mix them with different fubftances, and to digeft them alone, and, in mixture with thofe fubftances, to try the different events.

Mr. Geoffroy made a multitude of experiments on the *oil* of thyme with this view, and, from the events of thefe, has made feveral very fair deductions as to the caufes of the different colours of the flowers of plants.

A large quantity of dried thyme being diftilled with water, in earthen cucurbits, yielded him a pure deep yellow *oil*; this he rectified by diftilling it again, with a great quantity of water; and, by this means, obtained a pale yellow *oil*, which he ufed for all his experiments.

He divided the *oil* into feveral parcels, and with one he mixed diftilled vinegar; with others the acid fpirits of nitre, vitriol, and fea falt, feverally reduced by a mixture of water to the ftrength of common vinegar, which is about the ftandard of the acidity found in the juices of plants. All thefe mixtures were fet in digeftion, and the *oil* became of a deep faffron colour. If the acid fpirits had been ufed in their native ftrength, they would have immediately burnt up the *oil*. Another parcel of the *oil* was digefted with fpirit of fal armoniac made with lime. This paffed all the degrees of yellow, of red, and of purple; and finally became of a true violet-blue. Spirit of urine, and that of fal armoniac with falt of tartar, produced alfo the fame changes, except that the degrees of colour differed.

On the contrary, the fixed alkali of *oil* of tartar digefted with the fame *oil*, only changed it to a deep brown. *Oil* of tartar added to the *oil* with fpiris of fal armoniac, when it is yet only of a fine purple, turns it to a deep blue; and diftilled vinegar mixed with it in the fame ftate, turns it to a deep blackifh colour; this mixed with fpirit of wine, tinges it to a greyifh colour; and a little *oil* of tartar being then added, it becomes green, and that colour does not go off. If diftilled vinegar be added to this mixture, it deftroys at once the alkali, and the green colour which was owing to it, and gives the *oil* its original yellowifh hue.

Oil of thyme which has been made blue by means of *oil* of tartar, being mixed with fpirit of wine, the whole appears grey, and, on adding more *oil* of tartar, it becomes blue; diftilled vinegar takes off this blue colour, leaving the liquor redifh; and more *oil* of tartar makes it blue again.

It appears from thefe laft experiments, that *oil* of tartar acts differently on the *oil* of thyme, according to its different ftate; turning it blue or green, according as it is rarified, or concentrated. It fhould feem alfo, that the fpirit of wine contained a latent acid, fince all its effects on the *oil* of thyme are overpowered by a mixture of *oil* of tartar.

Mr. Geoffroy was at the pains of trying this whole courfe of experiments on feveral other *effential oils*, as thofe of lavender, juniper, turpentine, and others; but they did not produce the fame effect on all. Hence it appears that there is great difference between the *effential oils* of different plants, in regard to the effects of other bodies on them.

The fame courfe of experiments he tried on other *oils*, not of the vegetable kingdom, and, among thefe, he found none, except that of yellow amber, which at all approached to the nature of *oil* of thyme.

This *oil*, mixed and digefted with fpirit of fal armoniac, acquires a purple colour; *oil* of tartar mixed with this, does not change its colour, but when fpirit of wine is added to this mixture, the *oil* of tartar becomes blue, while the *oil* of amber continues of its purple colour.

There feems to be a certain degree of denfity neceffary in an *oil* to render it capable of all the changes of colours; this denfity feems perfectly hit in the *oils* of thyme and amber, and all the changes of the colours that are given to them, feem only the effect of rarifying, or condenfing them. If they are rarified to the utmoft, by being mixed with fpirit of wine, they become colourlefs and tranfparent; and, if condenfed in the higheft degree, as in the experiment with the diftilled vinegar, they become blackifh. Thefe are the two extremes, and all the other colours are but degrees and fhades approaching to, or receding from, one or the other of thefe. The *oils* naturally more rarified, fuch as *oil* of turpentine, and the like, have naturally no colour, nor can receive any from thefe proceffes; only if the mineral acids be mixed with them in their full ftrength, they burn them up to a fort of refin, and, finally, to a black mafs, refembling charcoal. But, perhaps, future attempts may teach us an art of fo modifying the particles of thefe *oils* as to render them fufceptible of all the changes that *oil* of thyme is.

The colours of the leaves and flowers of plants are of the fame nature with thofe produced in the *oil* of thyme, in thofe proceffes; and, as chemifts, in general, agree that all colours are the refult of fulphurs differently acted upon by falts; perhaps, great light may be given into their nature and origin from thefe experiments. Mem. Acad. Par. 1707. See the article *Colours of* FLOWERS.

The *effential oils* of vegetables may be divided into two claffes, according to their different fpecific gravities, fome floating upon water, and others readily finking to the bottom thereof. Thus the *effential oils* of cloves, cinnamon, and faffafras, readily fink, but the *oils* of lavender, marjoram, mint, &c. fwim upon the water. The lighteft of all the *effential oils*, is, perhaps, that of citron peels, which even floats on fpirit of wine; and the heavieft of them feems the *oil* of faffafras.

For the obtaining the full quantity of the more ponderous *oils* from cinnamon, cloves, faffafras, &c. it is proper, 1. To reduce the fubjects to fine powder. 2. To digeft this powder for fome days in a warm place, with thrice its quantity of foft river water made very faline with the addition of fea falt, or fharp with *oil* of vitriol. 3. To ufe the decoction left in the ftill, inftead of common water, for a frefh digeftion. 4. To ufe alfo, for the fame purpofe, the water of the fecond running, after it has been cleared of its *oil*. 5. Not to diftil from too large a quantity of the fubject at once. 6. To leave a confiderable part of the ftill empty. 7. To ufe a brifk fire, or a ftrong boiling heat at firft, but to flacken it a little afterwards. 8. To have a low ftill-head; with a proper internal lodge, and current, leading to the nofe of the worm. And, 9. To cohobate the water, or pour it back upon the matter in the ftill, after feparating its *oil*, and repeating this once or twice more. *Shaw's* Lectures, p. 141.

Effential oils, when applied to the human body, ftimulate, erode, refift putrefaction; and, mixed with the blood, raife fome degree of fever. Med. Eff. Edinb. Vol. 5. Art. 24.

The vegetable world affords vaft variety of *effential oils*, moft of them very odorous, and of great virtues.

The *effential oils* of many of the plants ufually diftilled have their peculiar refervoirs in the plant. Mr. Geoffroy perceiving this, determined to fearch for them through the different parts of the plants, and enquire into the reafon of feveral precautions which are always found neceffary, in order to fucceed in the diftillation of them. See OIL-*bladders*, infra.

From what has been faid above, it appears, that the *oils* in common ufe are of three different kinds. The firft are mere *oily*, or fatty bodies, extracted either by expreffion, or by decoction: of the firft kind are thofe of almonds, linfeed, nuts, olives, and the like; and of the other, that of bay berries, and the like, which are procured by boiling the fubftance, on which the *oil* collects itfelf on the top of the water.

The fecond kind of *oils* are thofe extracted from vegetables, by common diftillation by the alembic, with the help of water; thefe contain the *oily* and volatile part of the plant, and carry, by way of pre-eminence the name of *effential*, or *etherial oil*.

The third fort of *oils* are the fetid ones, which are, in like manner, produced by diftillation, but by means of a different diftillation in a naked fire, and without the affiftance of water.

It seems to follow from this account, that the *ethereal*, or *essential oils* are the volatile exalted sulphurs of those plants; and as sulphurs are the basis of all smells, it is easy to be presumed, that all sweet-scented plants have an *essential oil* in some of their parts The balsams, and resins, which we find in many vegetables, seem to have their origin from the *essential oils* of the trees or plants they belong to, and which are usually found greatly to abound with them. Indeed, in the balsamiferous trees, the liquor which flows out on wounding the trunk, may very properly be esteemed a sort of *essential oil* of a harder consistence than the common ones. Of this nature are the balsam of Capivi, of Gilead, and the rest; and these very *oils*, farther indurated, furnish us also with the scented resins, such as benjamin, myrrh, and the like.

All *essential oils* become thick and resinous on being mixed with any foreign acid; they also acquire the same consistence of themselves in long keeping, and that partly from the same principle; their subtler parts evaporating give room for the acid salt, which they naturally contain, to display its power; and being then in an over-proportion to the rest, it does not fail to act upon the whole in the same manner that any other acid would. Thus the *oil* remains no longer what it was, but becomes a resinous substance, of a smell resembling turpentine.

Chemistry is not, however, without its resource on this occasion; for this thickened *oil* being mixed with a large quantity of water, and distilled in a balneum mariæ, a great part of it will come over with all its wonted fluidity, limpidity, and odour; but even this new distilled *oil* is not exempted from the same change again. This disadvantage in the keeping the *essential oils* distilled in the common way, has occasioned Mr. Geoffroy to contrive another method of making them. This renders them more limpid and fluid than in the common way, and they are never subject to grow thick; but the medium not being water, so much of the *oil* cannot be procured from the subject, because some is absorbed and stained in the medium. The instance this gentleman gives of his new method is in the essence of citron, and is this:

A common alembic is to be filled with the thin pared, external rinds of the fruit; a sufficient quantity of spirit of wine is to be poured on these, and the vessel being well closed, the whole is to stand some time in digestion; during this time, the spirit charges itself with a vast quantity of the *essential oil* of the bark, and being carefully distilled in balneo mariæ, it brings over with it a great deal incorporated in itself, but, beside that, there is a large portion swimming on the surface of the spirit, and easily separable from it in the common way: this is as clear, pellucid, and thin, as the spirit itself, and is, in all respects, superior to the essence made by any other means. The spirit of wine may be saved for a second operation of the same kind, and there will then be no loss from it; for being already sated with as much of the *oil* as it naturally absorbs, it will take in no more by the same means, and therefore may serve for ever so many new distillations, without loss. If all the *oil* be finally desired to be separated from the spirit, it may easily be obtained by mixing the spirit with a large quantity of water, as is done in making the *oil* of spike. The *oil* will then swim at top, and the spirit may be separated again from the water by distillation.

Some of the *essential oils* are so abundantly charged with salts, that, in long keeping, they will actually deposit plain concretions of the saline kind. This is frequently observed in *oil* of turpentine, which, though ever so well rectified, will yet affix long crystals like needles to the sides of any vessel in which it has been long kept; the *oils* of marjoram, and feverfew, do the same; as also several of the others. All the other *oils* also suffer great changes in keeping; that of juniper becomes thick like turpentine, in a short time; and those of sage, and of rosemary, after some keeping, are not distinguishable from one another. The age and state of the plant may also make great difference in the smell of the *oil*, and there have been many instances of the *oil* of sage becoming wholly like camphor in keeping. The distilled *oils* of some plants vary also at times in their colour. The *oil* of rue, and that of wormwood, sometimes come over green, and sometimes brown; the *oil* of chamæmile in Italy is always blue, but Mr. Geoffroy says, that he could never get a blue *oil* from the chamæmile of France by a simple distillation; and as to those *oils* which sometimes are green, they all become of the common clear yellowish colour of the other *oils*, if rectified by distilling them over again in a balneum mariæ.

In dry seasons wormwood affords but little *oil*, accompanied with a bituminous matter, or a genuine resin; and, in these seasons, if the young shoots only are distilled, the *oil* is almost constantly found to come over green; but in moist years the wormwood yields a much larger quantity of *oil*, and it is then always brown. Wormwood which has grown on dry sandy soils is always more white, and woolly, on the leaves, and always affords an *oil* of some tendency to a greenish colour; while, on the contrary, such as grows in rich moist ground, has larger, and less woolly leaves, and yields a brown *oil*. The season, and degree of heat, added to this difference of soil, may also make greater changes than could be imagined in the *oils* of plants. Mr. Geoffroy assures us, that he once made, in a dry season, from a quantity of thyme which had grown in a dry soil, an *oil* as pure, as limpid, and as sweet and high-scented, as that of the hotter countries, whereas the *oil* of thyme made in France is usually much poorer, and of an obscure colour, and coarse earthy scent.

The *oils* of plants have not always the same tastes with the plant they are distilled from, or, at least, not in the same degree. Nothing is more bitter than wormwood, yet the *oil* of wormwood has no remarkable bitterness. Anise, which is of a sweet taste, yields, on the contrary, an *oil* infinitely more sweet than the seed; and pepper, which is so remarkably hot and acrid, affords an *oil* no way remarkable for its pungency. Thyme, which is in itself very acrid and pungent, conveys that property, in a yet greater degree, to its *oil*; there is, indeed, no *essential oil* so acrid and firey as that of this plant. The fetid *oils* drawn in dry distillation by the retort, in an open fire, no way differ from these but by the damage the fire has done them, and may always be converted into these by repeated distillations. Nay, the very fat *oils*, such as that of almonds, may be attenuated so far as to become as fine, and as subtile, as the *essential oils*. This is to be done by means of quick lime; and several repeated distillations of this *oil*, or any other of a like kind, with fresh lime to every distillation, will reduce it to be volatile, penetrating, and capable of being raised, and distilled, by means of water, which is the great test of the *essential oils*. The bituminous, and fetid *oils*, may also, in the same manner, be reduced by repeated distillations, to the state of the *essential* ones, and to be equally fluid, and limpid, and equally penetrating. Memoirs Acad. Par. 1721.

Adulterations of essential OILS. Many of the *essential oils* being dear, it is a very common practice to adulterate, or debase them, several ways, so as to render them cheaper both to the seller and the buyer. These several ways seem reducible to three general kinds, each of which has its proper method of detection. These three ways are, 1. To adulterate them with *expressed oils*. 2. With alcohol. And, 3. With cheaper *essential oils*.

If any *essential oil* be adulterated with an expressed *oil*, it is easy to discover the fraud by adding a little spirit of wine to a few drops of the suspected *essential oil*, and shaking them together; for the spirit will dissolve all the *oil* that is *essential*, or procured by distillation, and leave all the expressed *oil* that was mixed with it untouched.

If an *essential oil* be adulterated with alcohol, or rectified spirit of wine, it may be done in any proportion, up to that of an equal quantity, without being easily discoverable either by the smell, or taste. The way to discover this fraud is to drop a few drops of the *oil* into a glass of fair water, and if the *oil* be adulterated with spirit, the water will immediately turn milky, and by continuing to shake the glass, the whole quantity of spirit will be absorbed by the water, and leave the *oil* pure at top. *Shaw's* Lectures, p. 145.

Finally if an *essential oil* be adulterated by a cheaper *essential oil*, this is commonly done very artfully: the method is to put fir-wood, turpentine, or *oil* of turpentine, into the still, along with the herbs to be distilled for their *oil*, such as rosemary, lavender, origanum, &c. and, by this means, the *oil* of turpentine distilled from these ingredients comes over in great quantity, and is intimately blended with the *oil* of the genuine ingredient. The *oils* thus adulterated always discover themselves in time, by their own flavour being over-powered by the turpentine smell; but the ready way to detect the fraud, is to drench a piece of rag, or paper, in the *oil*, and hold it before the fire; for thus the grateful flavour of the plant will fly off, and leave the naked turpentine scent behind.

Fern OIL. See the article FERN.

Green OIL, *oleum viride*, a form of medicine prescribed in the late London pharmacopœia, and made in the following manner. Take leaves of bay, rue, marjoram, sea wormwood, and chamæmile, each three ounces; *oil* of olives a quart. Boil the herbs in the *oil* till they are crisp, and then strain off the *oil*, and when it has stood for the fæces to subside, put it up for use. *Pemberton's* London Disp. p 350.

Red OIL, in the porcelain manufacture, a name given to a peculiar colour used on the China ware, or to those pieces of the ware which are coloured with it. It is a very elegant ornament, and would be worthy our attempting to imitate in England, on our better sorts of wares. They do it in the following manner: they mix the red colour called *tam-lan-hum*, or the copperas red, before described under the article of COLOURING *of china*; this they mix with *oil* of stone, (see OIL *of stone*.) and with another *oil*, as they express it, of the same kind, made of a whitish sort of pebble, or agate, found on the shores of their rivers, and the place of which might probably be supplied with us by common chrystal. The powder is to be thoroughly mixed with these liquors, and the vessel dipt carefully into the mixture, or some parts of it only covered with it in figures: after this, it is to be set by to dry, and, when thoroughly dried, it is to be baked in the common way. The general method is that of covering the vessel all over, both inside and out with this red; and it comes out of the most bright and brilliant colour imaginable, but it will

not ring when struck upon, as our common china ware does. We seldom see this in any degree of perfection, but it is very elegant when fine. Observ. de l' Asie.

OIL *of the earth*, *oleum terræ*, in the materia medica, the name of a thick mineral fluid of a dusky brownish black, with a faint cast of purple, and of the consistence of a thin syrup, very little transparent, and of a strong penetrating smell, like that of common *oil* of amber. It ouzes out of the cracks of rocks, in several parts of the island of Sumatra, and some other parts of the East Indies, and is much esteemed there in paralytic disorders; but it is seldom imported into England, what our East India surgeons and captains usually bring over under this name, being only a vegetable *oil* impregnated with the virtues of certain of their fossils by boiling. *Hill's* Hist. of Foss 470.

OILS *inflammable with acids*. See INFLAMMABILITY.

OIL *of olives*. The *oil of olives* having been publickly declared in England to be a certain remedy for the bite of a viper, the person who made the discovery having suffered himself to be dangerously bitten, and recovered not only himself, but several animals bitten at the same time, by this remedy alone, and that before a number of persons of the greatest eminence in medicine, the royal academy at Paris were determined to give the *oil* a number of fair trials, and determine, beyond controversy, a point of so great importance, as whether this *oil* was, or was not, a remedy for this terrible poison.

These experiments they have related in their memoirs; to these they have added the state of the bodies of animals, when opened, after they had died of these bites; and to these they have subjoined some very useful reflexions. They occasioned several pigeons, some young chickens, two cocks, a goose, a turkey, two cats, and eight dogs, to be bitten by vipers; in examining the wounded part, there usually appeared at first only two little red spots, though sometimes a small quantity of blood, and very soon afterwards there began to appear a tumor, which, by degrees, encreased and extended over the neighbouring parts. The creatures were bit in the thigh, or leg, and the whole limb soon after became livid, and the swelling, and colour, extended thence over the lower part of the belly; and this was commonly followed by vomiting, and convulsions. The birds often bent their necks forward as if to vomit, and threw up only a quantity of phlegm, and death usually soon followed these symptoms.

Of four pigeons which were bitten by four different vipers at the same time, and to which nothing was done to prevent the effect of the poison, they all died in a quarter of an hour, half an hour, or at the utmost, a little more than an hour. Two other pigeons were bitten, and about three minutes afterwards the parts wounded were rubbed with *oil of olives* warmed; but notwithstanding this, they both died, the one in twenty-five minutes, the other in an hour and half. Two other pigeons were bitten after this, and the wounded parts immediately rub'd with *oil of olives*, made very hot, without heating the part; the one of these died in fifteen minutes, and the other in an hour and half. These had all been bitten on the thigh. They next caused a pigeon to be bitten on the wing, and applied the *oil* immediately, but the bird died in five minutes.

After this, eight pullets were bitten on the thigh. No application was made to any of these, they all shewed the marks of being bitten, yet two of them escaped alive. Of the others, one lived an hour; two that had been bitten, both by the same viper, perished; that which was first bitten, in an hour, the other in an hour and a quarter; and the other three, which were bitten by a viper which had, before that, bitten another animal, perished; the first in an hour, the second in about seven hours, and the third in an hour and half.

Eight other pullets were afterwards bitten by vipers, and the hot *oil* was applied to the wounded part at different times afterwards, but none were suffered to remain longer than ten minutes without it. Of these animals, three were saved; the others died in a very little time: notwithstanding the application of the *oil*, one of them only excepted, which lived to the day after, but then died.

Six other pullets were first rub'd over with *oil* on the part intended to be bitten; and, after the bite, the *oil* was carefully applied hot to the part several times; but notwithstanding this, they all died. One of them lived six hours, but the others all perished in a very short time after they received the poison.

Two large cocks were next bitten; to one of them the *oil* was applied soon after he received the wound; but he, notwithstanding, died in three hours. The other cock had not the *oil* applied, but an actual cautery was brought near the wound, and held there about three minutes; this creature perished also in about two hours.

A goose was next bit by a viper, and the bite seeming doubtful whether it had penetrated farther than the skin, another viper was made to bite it a second time; the *oil* was applied immediately afterwards to the wound, and the application continued a long time with frequent repetitions; but, notwithstanding this, the usual symptoms appeared, and the creature died in two hours and a quarter. A large turkey was next bitten, and the two first bites appearing dubious, he was wounded a third time; the *oil* was applied in time, and repeated many times; but, notwithstanding this, the usual symptoms appeared, but after about three hours they abated, and the creature continued out of order for three days, and finally recovered. Eleven days afterwards the same turkey was again bitten by a viper, and no application was made; he was sick again for about two days, but at the end of that time he recovered.

A young kitten was bit on the nose by a viper; the *oil* was applied, and the creature was well the next day. A grown cat was bitten by four vipers, and the *oil* was applied; the creature made her escape, but she was seen alive afterwards. Eight dogs were bitten, some on the thigh, some on the nose, and others under the belly. Three of these had no application made to them; a tumor, and lividness succeeded the bite, but they all recovered, as well as the other dogs who were rub'd with the *oil*; one of these was a young puppy. The last dog that was bitten was of the Danish breed, and was very large, though but two months old; he was bitten by several vipers, and that in several parts, and the application of the *oil* was not made till after an hour and half. The tumors on the bitten parts growing very large, there were scarifications made in them, and hot *oil* poured into them. The creature shewed many signs of convulsions; his breath grew hard, his limbs failed him, he vomited, and purged, and, in fine, he died about eight-and-forty hours after the biting, notwithstanding this close application of the *oil*.

From these experiments, there is little credit to be given to this boasted remedy. The pigeons which were bitten by vipers all died, notwithstanding all that could be done by it; the article of the pullets is not at all more favourable to it; some having escaped to which it was applied, and others died; and of those which were bitten, and had no application made to them, some also lived; and the *oil* was found to produce no good effect in a great many others in the same circumstances. The turkey which lived with the application of the *oil*, we find could live also without it; and though some dogs lived which were bathed with *oil* after the bite, some also lived to which nothing was applied, and the *oil*, with all favourable circumstances, we see, could not cure the Danish dog: so that, upon the whole, if the *oil* be a remedy for the bite of a viper, it is, at least, a doubtful one, and far from the infallible cure it was supposed to be.

The great instance of the man's being recovered who was bitten on purpose to try the experiment, is far from proving the *oil* an infallible remedy, since he had other remedies administered to him, and there have been several instances of men being cured by these without the application of the *oil*. And it is to be observed, that the bite of a viper is not always certain death to a man, if he use no remedies at all, but that many have recovered, notwithstanding that the symptoms which affected that person have appeared upon them. We see very plainly by the before recited trials, that of several animals of the same kind, bitten at the same time by vipers, some have recovered, and others have died, and this equally when this supposed remedy was, or was not, applied to them And, in the same manner, it may happen to men, that of numbers who have been bitten, some would recover, and others die, whether any means were used, or not. Memoires Acad. Scienc. Par. 1737. See the article POISON.

OIL *of sassafras*. Many of the vegetable *oils* obtained by distillation, will be found, under certain circumstances, to approach to camphor. The *oil* of thyme may be crystallized, according to a process of Mr. Newman's, who calls it, in that, *camphora thymi*. Phil Transf. N° 479. p. 379.

The *oil* of sassafras is peculiarly liable to crystallization in certain circumstances, and that into the most beautiful forms. Mr. Maud gives an account of a quantity of this *oil*, which having stood exposed to the air in a very frosty night in an open vessel, was in the morning found changed three parts in four of it into very beautiful and large crystals: they were of an hexagonal form, very transparent, and of three or four inches in length, and half an inch in thickness. These crystals subsided in water, and were indissoluble in it; they were readily inflammable at the fire, and were reduced by heat to their pristine fluid state: hence it is evident that they still retain the natural qualities of an *oil*, though they appear under so very different a modification of their parts. What is most remarkable in this change, is, the metamorphosis of a fluid to a solid body, of so determinate and regular a figure, and that these crystals should be perfectly clear and colourless, though the liquor from which they froze, was of a yellowish colour, not unlike that of Madeira wine.

This seems to afford a new instance of crystallization, which is generally accounted for by the particles of a fluid, or those of any other body suspended in a fluid, being brought nearer by cold, and, at length, coming within the sphere of each other's attraction, unite together into an immediate contact. This *oil* being a very heavy fluid, much heavier than water, is the more likely thus to unite, as its parts are nearer together. This may be a hint to the curious to discover wherein consists the difference of solidity and fluidity; and it likewise shews how

how much the colour of bodies depends upon the mechanical situation of their parts.

OIL *of stone.* In the manufacture of the Chinese porcelain, they use a liquid matter of a white colour, which they call by this name, on which their great mystery of finishing their work depends; yet this has been less enquired into by the imitators of that ware in Europe, than many other articles of less consequence. The stone of which this *oil* is made, is of the same degree of hardness with that which the petunse is prepared of. They procure it from quarries, and chuse such as is of a good white colour, and has many dark green spots in it.

These spots are of the colour of the leaves of cypress. Sometimes a stone is chosen which has a brown ground, variegated with spots and blotches of a reddish colour. They first carefully wash this stone; then laying it in a clean place, they break it to pieces with iron instruments, and afterwards grind these to a perfectly fine, and impalpable powder, by rubbing them in large mortars, with pestles of stone faced with iron, and turned either by the labourers, or by water. When the whole is thus reduced to a fine powder, they throw it into a vessel of water, and stirring it briskly about, they let the coarser part subside to the bottom, and there swims a fine thick matter like cream, for two or three inches depth, on the surface. This they carefully scum off, and putting it into another vessel of clear water, they let it throw down any coarse matter it may yet contain; and, finally, taking off the thick surface again, they mix this with some fresh water in another vessel, and leave it to subside; then pouring off the clear water, they take out the remainder at the bottom of the vessel, which is perfectly fine, and resembles a thick cream. To every hundred pounds of this, they add one pound of a substance of the nature of which we are not yet perfectly informed. It is said to be a mineral resembling alum. They calcine this first, and then beat it to a fine powder, and this being added to the cream, or *oil*, as it is called, serves to keep it always in the same liquid state. This substance, when finished in this manner, has very little title to the name of an *oil*; it is rather a varnish, and is always used in mixture with another varnish, which is called at this time fern *oil*, and used to be called lime *oil*; it is prepared in the same manner with the other after burning. See FERN-*oil*.

OIL *of vitriol.* See the article VITRIOL.

OIL *of wax.* See the article WAX.

OIL *bladders*, in plants. — It is a discovery, partly of Mr. Tournefort, and partly of Mr. Geoffroy, that the essential *oils* of all plants are contained in their perfect and pure state, in the plants themselves, while growing; they have, in different vegetables, different parts assigned for their reception; in some the flower; in others, the flower cup only, as in rosemary, and the like; in others the bark; in some, the parenchyma of the root; and in others, the wood.

Wherever they are lodged, they are always contained in these vesicles, or capsules, which require only to be broken, or burst open, in order to set them loose; this is effected by the boiling water in the common distillations, and the natural subtilty and lightness of the *oil* then makes it easily rise in vapour, and its oleaginous quality rendering it incapable of mixing with the water, it swims at the top, and is easily separated.

These vesicles are most usually placed in, or about, the flower, and it is in many plants a very easy matter to trace them to their several places of principal residence. Mr. Tournefort has observed that these *oil bladders* in the fraxinella taking their origin at the root, thence ascended to the fruit or covering of the seeds. This plant has a very remarkable variety in its *oil* in the different parts. The flower is sweet-scented; the vesicles placed along the stalk contain a very sharp and acrid *oil*, somewhat resembling the essence of lemons, when kept a long time. The leaves have scarce any sensible odour, but the root has a scent peculiar to itself, and different from that of all the rest of the plant. *Geoffroy*, ap. Memoires Acad. Paris 1721.

The essential *oil* of cinnamon has also a difference of the same kind, which is owing to the different fluid contained in the vesicles in different parts; the bark of the root yields an *oil*, which, after keeping some time, always yields a pure and genuine camphor; whereas the *oil* of the bark from other parts of the tree has nothing of this property.

It is also easy to observe, that the capsules of certain fruits have more odour than the fruits themselves. The coat which covers the pistachia nut, contains much more essential *oil* than its kernel; and the bark which surrounds the amomum, and cardamoms, has much more smell than the kernel of the seed. The first bark of the nutmeg is well known to have a more fragrant smell than the nutmeg itself, being the mace; yet there is, within this, another covering of that fruit, which has no scent at all.

Most of the seeds of the umbelliferous plants, which usually pass for aromatics of the first and most eminent kind, have, in reality, no smell at all in themselves; the *oil bladders* which yield their virtues being placed in their outer covering, the kernel within the seed usually containing a fat *oil* of the olive or almond kind, and wholly different from the essential. The *oil* of aniseed made by expression is fluid, of a green colour, and of a fatty nature, but is highly scented with the *oil* which it has taken with it from the covering; on the contrary, the essential *oil* procured from the same seed by distillation, is thin, not fatty, of a much more clear and penetrating scent, of a pale colour, with no admixture of greenness, and readily concretes into a mass like butter on external cold. In coriander seed, the kernel carefully separated from its membranes has no smell, and contains only a fatty *oil*, like that of the olive, while the vesicles are all ranged in the rind, and therefore in that alone is the aromatic smell. These vesicles in the skin of fruits are the occasion of the sweet flavour of many; as of the strawberry, raspberry, and the like; in these they are too small to be distinguishable, while, in the thicker rinds of the orange and lemon kind they are easily discerned, and, on the least pressure, burst, and throw out their contents, which make what we call the *zest*, and which is separated in this manner in greatest quantity in hot countries, and where there are plenty of the fruit, is preserved under the name of *bergamot*, and other essences of a like kind.

There is, however, no subject in the vegetable world in which these vesicles are more plainly perceived than in the berries of the juniper, a fruit very well known, and in constant use with us. These berries are at first green, afterwards of a reddish brown, and finally black, and they are two years in coming to maturity. The berry is formed at the top, in the manner of a bud of the rose, or piony, which is just ready to open; and it sometimes does open into four or five parts, according to the number of seeds it contains. It contains, beside these, an acrid, a sweet, and an aromatic juice, which leaves a sensible bitterness behind it in the mouth.

In order to account for these so different tastes in the same fruit, Mr. Geoffroy attributes its acrid quality to the skin, or husk, and in some berries, indeed, to the unripeness of the whole, for want of a due heat of the weather; the sweet taste is from the juice of the fruits which is properly a saccharine or melleous liquor, and the aromatic flavour is wholly owing to the *oil* which is lodged in the vesicles expanded over the whole inner substance of the fruit. These substances are indeed so determinately marked in the berry, that it is possible to separate them; but these are not all the differences of taste and matter in this little fruit, every kernel of which has in it five or six vesicles, lodged each in a peculiar, and appropriated cavity, in the external part of the seed. These are easily separated from the rest of the fruit, and, when that is dry, are found to contain an absolute resin; they are of a dusky colour, and each drop of resin in them is of an oval figure, and is very bitter to the taste; hence therefore is the remarkable bitterness that affects the mouth, when the berry is thoroughly broken by the teeth.

The knowledge of this may be of great use to the apothecary in his medicinal preparations of juniper berries of several kinds. When he wants only the extract, which is the melleous juice of the berries alone, they ought not to be stamped or bruised, to dislodge this resin, which has no business there, but should be only boiled, and the decoction inspissated. But when the essential *oil* is required, the whole berry must be bruised, and that in a thorough manner, that all its kernels be broken. The cells, or vesicles of *oil*, now indurated into a resin, burst open, and the whole dispersed in such a manner that water may affect it. Memoires Acad. Par. 1721.

In order to discover what are the parts of a plant in which the *essential oil* most abounds, it will be proper to examine what part yields the most smell; and this will be found different in different plants. In some the seat of odour occupies the whole body of the flower; in others only some particular part of the flower has it, and in some; it is principally lodged in the covering; and in some it is dispersed every way, thro' the body of the fruit. In some instances it is found lodged in other parts of the plant, and sometimes it is equally strong in every part of it.

This principle of the *essential oils* varies also not only in regard to the place where it resides, but in the different scents it yields in different places; or in the same parts of the plant in different seasons. Thus the leaves, stalks, and roots of the violet have no smell, while the flowers have a great deal. All parts of the jasmine tree are without scent in like manner, except the flowers, which are very sweet. And the case is the same in the tuberose, the jonquille, &c. in all these plants the *essential oil* is very volatile, and in very little quantity; their reservoirs are so obscure, that we cannot find the least trace of them; and, instead of an *essential oil*, all that can be obtained from them by distillation, is a sweet-scented water, and even this loses its smell in a very little time. Of this sort also are the flowers of the lime tree, the lilly, and the clove julyflower; in these there is no part scented but the extremities of the flowers, and then not till they are thoroughly opened; and, for this reason, if we would obtain a sweet scented water from these, we are to use no part but the flower, and that not till perfectly expanded on the extremities

tremities of the petals; and, with all the caution that can be taken, the water distilled from these will have but very little smell, if the season chance to prove rainy.

This is not the case in the wallnut tree flowers; these contain a large quantity of *essential oil*, and, consequently give a very strong-scented water; but this water very often varies from the smell of the flower, acquiring in the distillation the smell of the bitter almond: the reason of this is, that the embryo fruit is contained in the flowers, and it is that which is the principal source of the *oil*, and the *oil* it yields is wholly analogous to the fruit of the bitter almond.

Peach blossoms afford a very sweet-scented water, and their young leaves have a smell like that of bitter almonds, and in general, the same observation may be extended to all those plants which have bitter kernels in the fruit. It is observable, that among the radiated flowers, such as that of colts foot, and the like, the flower itself has little or no smell, but whatever scent we perceive in it, arises from the cup, whose scales, or constituent leaves, have either a velvety down, or a series of vesicles which contain all the *essential oil*, and, consequently, all the odour When flowers of this kind are to be distilled for their *oil*, they must, therefore, be used before they are blown open, as the vesicles are then in their finest state. These vesicles are so large and numerous in hot seasons, in the cup of the marygold, the sun-flower, and some other such plants, that they are easily distinguished by the naked eye.

Balm has very little *essential oil*, and if it be not chosen for distillation in a very favourable time, its water will have scarce any scent at all. The most favourable time is, when the plant is fullest of vesicles, and that usually is when it is about six or eight inches high; its leaves appearing somewhat reddish, and being but of about half the bigness they are to grow to. This observation extends also to most of the plants of the same class, nay even to the woody ones, except that they are more aromatic; that is, that they contain a number of vesicles of an odorous resin, which is wholly owing to the closer and firmer texture of the wood.

Sage, while young, when its stalks are not yet grown woody, is all over odorous, even its stalks, as well as every other part, being full of these vesicles of sweet scented matter, which may be expressed on pressing them. When the *essential oil* of sage is to be drawn, the plant is always to be chosen in this state, and the more woody ones which have stood through a whole season, are always found to have lost the greatest part of their odour in distillation. The woody part of this plant has no smell; the outer bark, indeed, has some scent, but that very little.

The flowers of rosemary, sage, and lavender, and others of the same kind, though in the whole they yield a very sweet scent, yet the aromatic essence is not lodged in them where it might most naturally be supposed; that is, in the petals, for if we pull these clean out of the cup, as in the violet and clove we ought to do, the separated petals have very little smell, and that little is not essential to the petals, but is wholly owing to the breaking of some of the vesicles which are placed in the furrows of the cup, in which all the smell is contained, and which, being burst in the violently drawing away the flower, leave a little of their contents on it. Indeed, if these cups are observed with a microscope, or, but attentively, by the naked eye, they will all be found full of small bladders, which contain a pure *essential oil*, of a very high and aromatic scent.

Thyme and lavender should either have their tops cut off, and those distilled immediately, or else they should be gently dried, and both flowers, tops, and young leaves, be distilled, since those are endued with a very aromatic scent at their first shooting.

Among the trees, very many have sweet-scented leaves and flowers, while the wood has not the least odour; to draw the *oil* from these the young shoots are to be taken, since the vesicles which contain the *essential oil* are all lodged in these, and are at this time in their best state, the heat of the sun exhaleing afterwards their most volatile parts. Even the young wood of these shoots is capable of affording some *oil*, since in it, these vesicles are placed between the outer and the inner bark, but these are all perfectly destroyed before the wood hardens: this is the case in the orange tree, the myrtle, the bay, savin, and the like.

It is to be observed in the sweet scented woods, that the place where the resin is collected in greatest quantities, is in the knots from which young branches are to rise; this is very easily observable in the firs and juniper. This is not, however, the case in all the resinous woods; for some of these abound so in resin, that their several woody beds, or layers, are all connected to one another by beds of resin; as is the case in guaiacum, in the calambac wood, and that of aloes. And this is more peculiarly remarkable in the last; for in the finest wood of this kind sent from the East-Indies, the woody parts are stript away, and only these resinous beds are left remaining; and, consequently, while the coarser and cheaper sorts burn like our woods to a charcoal, this precious kind melts upon the fire like a true resin, and is the finest-scented substance imaginable.

In all the resinous woods, the young shoots of the tree are to be preferred for the extraction of the *essential oil*. This is well known to those who traffick largely in this way: And even the liquid balsams, of which enough cannot be obtained by incision, may be thus procured: they boil the tops of the branches, and the young shoots, in water, and collect from the surface of that liquor, the fluid balsam which the boiling has separated from the shoots, and which cannot mix with it.

Beside the parts of trees, and plants, already mentioned, as containing their *essential oils*, it is to be observed that nature has enveloped the young eyes, or buds, with numerous coverings, thick spread with the same resinous matter, the use of which is to defend them from the injuries of the air, and from the severities in particular of the winter. Some of these are filled with a soft and fine cottony down which encloses both the young leaves, and young flowers, as is the case in the horse chesnut; these are all externally covered with a number of thick and strong scales, laid closely one over another, and cemented down, as it were, with this resinous matter. These make a covering which spirit of wine easily breaks open, by dissolving the resin, but which water cannot affect, and which, therefore, is impenetrable to rains. This resin has its particular reservoirs also in the bark of the tree into which it rises with the sap. The young buds, or eyes, in the black poplar are of the same kind; they have the same downy substance for their lodgment, and the same natural balsam, as it may well be called from its sweet scent, for their defence. When the leaves of this tree grow larger, these scales fall off, and the leaves have then no more smell. The resin, or balsam, mixing itself with the sap which still remains somewhat aromatic.

It is not only the stalks, the cups, and the scaly eyes of plants, which contain their *essential oils*; for even the aromatic roots are not without their share of it. Rhubarb is no aromatic root, and yet the assistance of glasses will shew many lucid specks in it, which are truly small parcels of resin; and the florentine iris, and calamus aromaticus, contain great numbers of such lucid specks, or parcels of pure resin.

The stalk of angelica has a very aromatic smell, and the seeds have a very different one; the root also is very aromatic, its parenchyma being all filled with the vesicles which contain the balsamic essence. The plant of the elecampane has scarce any smell, while the root is very aromatic, almost all the vesicles of balsam being contained there. The seat of these resinous, or oily particles, is usually the whole parenchymatous substance of the root, especially in those roots which have no woody substance in the middle; such as rhubarb, and the like; and those which have woody matter in their middle, contain this aromatic substance in their bark; such are the roots of fraxinella, and the like, of which we therefore use in medicine, only the outer bark.

Thus we have traced the several reservoirs of the *essential oils* in plants, and, as for the manner of separating them from the subjects, it has been delivered above. See *Essential* OIL.

OIL *dregs*. See the article DREGS.

OISEAU, in conchyliology, the name of a peculiar species of oister, of so remarkable a figure, that it represents a bird with its wings expanded, and has a small protuberance at the hinge, representing a head, and a long process at the opposite end, which very well represents a tail. It is of a dusky reddish colour on the outside, and of a fine pearly hue within. When the outside of this shell is taken off, and it is nicely coloured, by cutting it down to a proper depth in every part, it is of a fine reddish yellow, and is the aurora shell of collectors.

OISTER, in zoology. See OYSTER.

OKE, an Egyptian weight, consisting of three rotolos, each of twelve ounces, at twelve drachms to the ounce, and sixteen carrats to the drachm. *Pocock's* Egypt, p. 178.

OKELA'S, in Ægypt, and some other of the Eastern countries, are a sort of indifferent buildings round a court, and commonly appropriated to the merchants of some particular country with their goods; as at Cairo, there is one for the merchants of Nubia, and the black slaves, and other goods they bring with them; and another for white slaves from Georgia. *Pocock's* Egypt, Vol. I. p. 37.

OKER, in natural history. See OCHRE.

OLD (*Cycl.*) — OLD-*works*, in mining, are such that are either fallen in, or stand unwrought. *Houghton's* compleat Miner, in the Explanation of the Terms.

OLDENLANDIA, in the Linnæan system of botany, the name of a genus of plants, the characters of which are these: The cup is a perianthium divided into four pointed segments, which are inserted on the germen of the pistil, and remain when the flower is fallen. The flower is composed of four petals of an oval figure, spread wide open, and twice as long as the segments of the cup The stamina are four simple filaments. The antheræ are small. The germen of the pistil is roundish, and placed below the receptacle of the flower. The style is simple, and of the length of the stamina. The stigma has a rim round it. The fruit is a

globose skinny capsule, composed of two cells, each containing a number of small seeds. *Linnæi* Gen. Plant. p. 49.

OLEA, *oils*. See the article OIL.

OLEA, the *olive tree*, in the Linnæan system of botany, makes a separate genus of plants, the character of which is, that they have a perianthium composed of one single leaf, small, and tubular; indented at the extremity into four divisions, placed erect, and falling with the flower. The flower is composed of one single petal, which is a cylindraceous tube, of the same length with the perianthium; its margin equal, but divided into four segments, each of them something indented in the middle. The stamina are two filaments, short, pointed, placed opposite to one another, and terminated by erect antheræ. The pistil is composed of a roundish germen, with a single stylus, which is very short, and terminated by a thick stigma, which is bifid, and has fringed edges. The fruit is smooth, and somewhat oval, having but one cell, and containing for its seed, one longish, oval, scabrous, and striated nut. *Linnæi* Gen. Plant. p. 2.

The characters of this genus, according to Mr. Tournefort, are these: the flower is of one leaf, and of the funnel-fashioned kind, and usually divided into four segments at the edges. The pistil arises from the cup, and is fixed, in the manner of a nail, into the hinder part of the flower. This finally becomes a soft and juicy fruit, of an oval figure, containing an oblong stone, in which there is a kernel of the same shape.

The species of *olive* enumerated by Mr. Tournefort are these: 1. The large-fruited *olive*. 2. The *olive* with smaller oblong fruit. 3. The *olive* with oblong, blackish-green fruit. 4. The white fruited *olive*. 5. The *olive* with small, roundish fruit 6. The *olive* with larger, oblong, fruit. 7. The large-fruited *olive*, with a very thick pulp. 8. The great *olive*, with oblong, and angular, almond-shaped fruit. 9. The *olive* with oblong fruit, of the shape of the cornel-berry. 10. The great, round-fruited *olive*. 11. The green, middle-sized, round-fruited, *olive*. 12. The early, middle-sized, round fruited *olive*. 13. The clustered, small-fruited, round *olive*. 14. The small-fruited, blackish-red, round *olive*. 15. The small, round *olive*, with fruit variegated with black and red. 16. The small, Lucca *olive*, with sweet-scented fruit. 17. The wild *olive* tree, with hard leaves, hairy underneath. 18. The Spanish wild *olive*, with hard leaves, hairy underneath, and with obtuse, pointed fruit. *Tourn.* Inst. p. 599.

OLEA is also the name of a stone described by Ludovicus Dulcis, and some other such authors, who attribute great virtues to it, and say it was variegated with several colours, as yellow, black, white, green, &c. It seems to have been some one of the common agates, to which their ignorance had prompted them to give a new name

OLEA *Bohemica*, in botany, a name by which some authors have called the *zizypha* or *zizyphus*, the wild *jujube* tree. *J. Bauhin*, Vol. 1. p. 27.

OLEANDER, in botany. See NERION.

OLEARIA, in natural history, the name of a genus of round-mouthed sea snail, or *cochlea lunaris*. It is of a very large size, capable of holding two quarts, and had its name *olearia* from its being antiently used in families, as the vessel in which they kept *oil*.

OLEASTER, in the materia medica, the name of the *sallow thorn*, or *sea buckthorn*, the *rhamnoides salicis folio* of botanical authors. *Dale*, Pharm. p. 282.

OLEUM, *oil*. See the article OIL.

OLEUM *medicum*, in the writings of the antients, a name given to a famous *oil* which had a quality of burning under water, in spite of all that could be done to quench it. It was called *Medicum*, because of its being produced among the Medes, and some have called it *oleum Medeæ*, because it was supposed to be that substance with which Medæa anointed the crown of her rival. Ammianus Marcellinus tells us, that if an arrow was anointed with this *oil*, and shot out of a bow against any inflammable substance, the whole immediately took fire, and, if any one attempted to quench the flames by water, they only burnt the more fiercely for it. The *venenum Pharicum* of Nicander is supposed to be the same thing with this *oil*, and to have been so called from Pharai, a town, not the name of a man, whom some imagine the inventor of it. Pharai is a town in Crete mentioned by Stephanus, and we find by the antients, that this poison was sometimes had from Crete. Nicander and Procopius are of the number of those who mention the violent and terrible effects of the *oleum Medeæ*, and all that they say is equally applicable to the *oleum Medicum* of others; so that they seem the same liquor Some tell us of a plant that produces this *oil*, but Pliny says that it was a liquid mineral bitumen, of the nature of naphtha, which is very probable; for some of these mineral *oils* are the most inflammable of any substances that we are acquainted with. Babylon is celebrated by many authors as the country which produced this terrible liquor, and all agree that Babylon is a place where naphtha is more common than in any other part of the world. Strabo tells us, that there is a white kind common there, as well as the foul or black sort. This white one may probably be the same with the *oleum Medicum*, and *oleum Medeæ*; but then it is to be observed, that the virtues attributed to it are too far exaggerated, as is very common with the antients in their accounts of strange things

OLEUM *Medeæ*, a name given by the antients to the mineral fluid, more generally known by that of *naphtha*. See OLEUM *Medicum*, supr. and NAPHTHA.

OLEUM *vitri antimonii*, in medicine, a name given by Basil Valentine, and others, to a famous preparation of antimony, which they keep as a secret, or, at least, declare in such terms as are unintelligible, and boast of, as the universal medicine. The learned Kerkring has given the process for making this red *oil* of the glass of antimony, but that in so enigmatical a manner, that he seems himself not to expect any body to understand him; and only says, in his own justification, that he has given it in plainer terms than any body had done before him. The author relates many wonderful things of this diaphoretic *oil*, on his own experience; particularly, the curing a confirmed dropsy, by throwing off the water by sweat; so that the patient, in a manner, swam in it, and the drops run through the bed, in all parts, to the floor. It were well if we could understand the process. *Kerkring* on Basil. Valent.

OLIGACTIS, in natural history, a name given by Linkius, and others, to a genus of star fish, consisting of those which have fewer than five rays.

OLIGAEDRA, in natural history, the name of a genus of crystals. See CRYSTAL.

The word is derived from the Greek ὀλίγος, a few, and ἕδρα, a plane, or side; and expresses a crystal which is composed of only a few planes.

The bodies of this class are crystals of the imperfect kind, being composed of columns affixed irregularly to some solid body at one end, and, at the other, terminated by a pyramid; but the column and pyramid being both pentangular, the whole consists only of ten planes, not, as the common kind, of twelve. See Tab. of Fossils, Class 3.

Of this genus there are only three known species. 1. A whitish one, with a short pyramid, found principally in Germany, and sometimes brought over to us, among parcels of common crystal. 2. A bright and colourless one, with a longer pyramid. This is found in Germany, and in some parts of England, as in the tin mines of Cornwal, and on Mendip hills. And, 3. A brown one, with a scabrous crust. This is produced only in the East Indies, and is well known by our lapidaries by its rough coat, and is esteemed the finest of all brown crystals. *Hill's* Hist. of Foss. p. 184.

OLIGOTROPHEROS, among the Greeks, a name given to the finer sort of bread made of the finest flower. They called it by this name because of the little share of nourishment it conveyed; and, by way of distinction from it, called the brown bread *polytropheros*, or much nourishing.

OLIVARIA *corpora*, a name given by some anatomical writers to two oblong processes of the medulla oblongata, thus called from their resembling an olive in shape.

OLIVE, *olea*, in botany. See OLEA.

OLIVE-*oil*. See OIL *of olives*.

OLIVE-*gum*. See the article GUM.

OLOC, in natural history, a name given by the people of the Philippine islands, to their *quail*. It is like ours in all respects, but much smaller.

OLOCENTROS, in natural history, a name given by the old Greeks to a small animal of the spider kind, whose bite was accounted mortal. It is the same with the *solipuga*, so called from its stinging, or biting most violently, in places, or seasons, where the sun had the most power, as Africa, &c. The name *solifuga* was a corrupt way of writing that word, and this seems also a false way of writing the word *heliocentros*, which signifies the same as *solipuga*. See HELIOCENTROS.

OVALIDIA, in botany, a name given by some authors to *chamæmile*. *Ger.* Emac Ind. 2.

OLY, a word used by some chemical writers to express the oily part of metals, seen, in some circumstances, swiming upon the surface of their solutions

OLYRA, a name given by many botanical writers to the *spelt corn*, the *zea*, and *triticum amylæum*, or *starch corn* of other authors. This is a sort of grain cultivated in many parts of Germany. It comes to a ripeness toward the latter end of autumn, and is used for the common food of the poorer sort of people. It is like the spelt wheat, but is somewhat less nutritive. Vid. *Dale*, Pharmac.

OMAGRA, a name given by some medical writers to the *gout*, when seated in the articulation of the humerus with the scapula.

OMBRIA. See the articles BRONTIA, and CERAUNIA.

OMBROMETER, a machine to measure the quantity of rain that falls. We have the description and figure of one in Phil. Transf. N° 473. p 12. It consists of a tin funnel, whose surface is an inch square, a flat board, and a glass tube set into the middle of it in a groove. The rise of the water in the tube, whose capacity, at different times, must be measured, and marked, shews the quantity of rain that has fallen.

OMELYSIS, a word used by Hippocrates, and others of the antients, to express the meal of barley, crude, or not parched. It is recommended, when reduced to the form of a pultice, by boiling in wine and oil, for curing all tumors of the tonsils. It is also recommended, mixt in water, to be drank in hæmorrhages of the uterus. Authors of later date have made the word *omelysis* stand for all sorts of meal, or flower, and some for an equal mixture of the meal of barley, linseed, and fænugreek seed, in equal quantities; a medicine used for horses. And Cœlius Aurelianus uses it frequently for a cataplasm made either of meal, or bread and water.

OMENTA, a word used by some anatomical writers to express the membranes of the brain.

OMENTUM (*Cycl.*) — *Falling down of the* OMENTUM. On large wounds of the abdomen, the *omentum* will frequently protrude itself through the wound, either alone, or with some portion of the intestines. When this is the case, the first business is to enquire whether the protruded part preserves its heat, moisture, and natural colour: if it is not found faulty in any of these circumstances, it must be gently returned, but when the straitness of the wound forbids this, the protruded part must be taken off close to the wound, and the wound healed according to the common form. The *omentum* in this case will adhere to the internal part of the wound, without bringing on any disorder, or inconvenience to the patient. But where the intestines fall out at the same time, the *omentum* is to be fomented by an assistant with warm milk and water, till the intestines are returned.

If any part of the protruded *omentum* be cold, dry, livid, putrid, or corrupted, the mortified part must be entirely cut off before the rest is returned, lest the neighbouring parts should be brought into consent, which would inevitaby prove fatal to the patient. The corrupted part is to be taken off in this manner: pass a waxed thread two or three times round the sound part of the *omentum*, near the place where it is injured, and fasten it with a knot, to prevent any hæmorrhage from ensuing after the reduction of it; when you have made a secure ligature, take off the corrupted part with the knife, or scissars, and return what is sound, leaving, at least, the length of a foot of the ligature hanging out of the wound of the abdomen, till it slips off from the sound part of the *omentum*. The wound must be dressed in the common way, the depending part of it being kept open by a large tent: and, at every dressing, the ligature must be pulled a little gently forward, till it has, at length, entirely slipped off from the sound part of the *omentum*. *Heister*'s Surg. p. 66.

OMER, in the Jewish antiquity See CORUS.

OMNES, in the Italian music, a Latin term which we sometimes find used for *tutti*, all, or altogether. See TUTTI.

OMOPLATO HYOIDÆUS, a muscle called also *coracohyoidæus*, and *ornohyoidæus*. It is a very long and slender muscle, much narrower than the sterno-hyoidæus, and situated obliquely on the side of the neck, or throat, between the scapula, and the os hyoides; it is a digrastic muscle, being divided into two fleshy portions, joined endwise to a short, middle tendon. It is commonly fixed in the lower extremity to the superior costa of the scapula, between the small notch, and the angle, and sometimes very near the angle, and, from thence, some anatomists have called it the *costohyoidæus*; from thence it passes over the coracoide apophysis, adhering sometimes to it by a kind of aponeurosis, or membranous ligament; and, from this adhesion, the name *coracohyoidæus* was given it before its main insertion was discovered. It is also very often fixed to the clavicula by ligamentary, or fleshy fibres, and sometimes inserted in the whole middle portion of that bone, being inseparably united with the sterno-hyoidæus: having past the clavicle, it is bent forward, and runs between the sterno-mastoidæus, and internal jugular vein, the small middle tendon being situated in this place; from thence it runs up to its insertion in the inferior lateral part of the basis of the os hyoides near the corner, and insertion of the sterno-hyoidæus, which it covers a little. *Winslow*'s Anatomy, p. 255.

OMPHACITIS, a name given by naturalists to a small sort of gall of the oak.

OMPHACIUM. See OMPHACION, *Cycl.*

OMPHACOMELI, a sort of *oxymel* made of the juice of unripe grapes, and honey.

OMPHALODES, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is rotated, and divided into segments at the edge. The pistil arises from the cup, and is fixed, in the manner of a nail, into the middle of the flower, and afterwards changes into a fruit composed of four capsules, containing flattish seeds affixed to a placenta, which forms a quadrilateral pyramid.

The species of *omphalodes*, enumerated by Mr. Tournefort, are these: 1. The Portugal *omphalodes*, with leaves like those of flax 2. The taller, Portugal *omphalodes*, with hound's-tongue leaves. 3. The little, spring, comfrey-leaved *omphalodes*, called by some *borrage-comfrey*, and *creeping*, *dwarf comfrey* *Tourn.* Inst p. 140.

OMPHALOMANTIA, a word used by some authors to express a sort of divination pretended to by the midwives and old women, of telling how many more children a woman is to have, by examining the number of knots on the umbilical cord.

OMPHALOTOMY, Ὀμφαλοτομια, the operation of cutting the navel-string of new-born infants. See UMBILICAL, *Cycl.*

OMPHALUS, (*Cycl.*) in natural history, a term used by the antients to express what they at other times called *umbunculus* in stones; that is, a small round and prominent spot, in the center of the stone.

The *zmilampis*, which was a kind of oculus beli found in the Euphrates, had usually a blue prominent pupil, and this was called *omphalus*, and *umbunculus*, indifferently, and so in other stones. The words have both the same origin, and are used to express its being like the button, or prominent piece, in the middle of a shield, called by the Greeks *omphalos*, and by the Latins *umbo*. See the articles ZMILAMPIS, and UMBUNCULUS.

OMPHAX, in the natural history of the antients, the name they gave to a gem of the pellucid kind, and of a disagreeable greenish colour, with a mixture of yellow. Pliny and some other old writers, make this a kind of the aqua marine, calling it the *beryllus oleaginus*; but the earlier writers very justly determined it not to be of the beryll kind, but properly a distinct species of gem; and, therefore, very properly called it by a peculiar generical name. *Hill*'s Theophrastus, p. 80.

OMOPLATÆ *octavus*, in anatomy, a name given by Spigelius, and others, to a muscle called by Winslow *the upper portion of the rhomboidalis*, but by Albinus, the *rhomboides minor*. What Winslow calls the lower portion of the rhomboidalis, he calls the rhomboidæus major.

ONAGER, in natural history, the name given by authors to the *wild ass*, a creature common in Syria, and some other places, and differing very little more from the common ass, than as creatures in their native wildness do from those of the same species kept in stables, and brought up to be domestic animals. The skin of this creature is very robust, and durable, and makes the common chagrin leather used by our case-makers, &c. its surface being rough with small tubercles. *Ray*'s Synop Quad. p. 63.

ONAGRA, in botany, the name of a genus of plants, the characters of which are these: the flower is of the rosaceous kind, consisting of four leaves, disposed into a circular form, and standing on a cup; from the upper part also of this cup, which is hollow, there arises a pistil which finally becomes a cylindric fruit, which, when ripe, splits open in four places, and is composed of four cells, each containing a number of angular seeds, which are affixed to a placenta.

The species of *onagra*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved, yellow-flowered, American *onagra*, called by authors the *yellow*, *podded willow-herb*. 2. The broad-leaved, American *onagra*, with paler, yellow flowers. 3. The large-flowered, broad leaved, American *onagra*. 4. The small, narrow-leaved, Canada *onagra*. 5. The red-stalked, small-flowered, narrow-leaved *onagra*. 6. The betony-leaved, American *onagra*, with rough fruit. 7. The American *onagra*, with large leaves, like those of arsmart, and with small yellow flowers. 8. The American *onagra*, with narrower, arsmart leaves, and large yellow flowers. 9. The shrubby, American *onagra*, with large yellow flowers, and leaves like the oleander. *Tourn.* Inst. p. 302.

ONAGRIUS *lapis*, a name by which some call the *asinius lapis*. See ASINIUS *lapis*.

ONCOS, Ογκος, in antiquity, was used to signify an ornament for the head, peculiar to those who offered sacrifice. Mem. Acad. Inscrip. Vol. 3. p. 134.

ONDEGGIARE, in the Italian music, signifies to return the hand beating time, not directly, but by degrees; as *ondeggiare la mano*, to keep it wavering in the air, or giving it two motions, before it is quite lifted up to end the bar, and thence to fall it to beat a first, second, or third time, of that, or another measure.

ONEIROGMOS, a word used by the antients to express *venereal dreams*.

ONEIROPOLI, Ονειροπολοι, in antiquity, persons whose business it was to make predictions from *dreams*. *Potter*, Archæol. T. 1. p 304.

ONEIROSCOPI, Ονειροσκοποι, in antiquity. See ONEIROPOLI.

ONION, *cepa*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the liliaceous kind, and composed of six leaves; in the center of it there stands a pistil which finally becomes a roundish fruit, divided into three cells, and containing roundish seeds. To this it is to be added, that the flowers are placed in spherical heads, and that the leaves, as well as stalks are tubular

The species of *onion* enumerated by Mr. Tournefort, are these: 1. The common, red-flowered *onion*, with red coats to the root 2. The common, white-flowered *onion*, with white coats to the roots 3. The *onion* with a turbinated root. 4. The oblong-rooted *onion*. 5. The scallion *onion*. 6. The fissile *onion*, or *cib ule*. 7. The great African sweet-rooted *onion*. 8. The perennial, rush leaved, sectile *onion*. 9. The fine-leaved, Alpine, marsh *onion*. 10. The smallest, Portugal *onion*, with capillaceous leaves, and purple flowers.

11. The fine-leav'd, bicomated *onion*, with dusky colour'd flowers. 12. The little rush-leav'd, purple flowered *onion* 13. The purple-flower'd, globular-headed, fine-leaved *onion*. *Tourn.* Inst. p. 382.

Onions are much eaten, and it would be well if they were yet more so; they attenuate tough humours, cleanse the stomach, and excite appetite, and in some degree promote the menses. But they are apt to breed flatulencies, and, if eaten too largely, to affect the head and disturb the sleep afterwards. An *onion* boiled to a perfect softness, is recommended by many as a cataplasm for ripening pestilential buboes. A fresh cut *onion* rubbed on the part till it become red, and itch, is said to be a cure for baldness. A mixture of equal parts of juice of onions and spirit of wine, is esteemed a cure for deafness, a few drops being put at times into the ears: An *onion* cut in two, and macerated an hour in the same spirit, is a good application for the head-ach. A cataplasm of roasted *onions* and butter is an excellent application for the piles.

The three sorts of *onions* propagated for the sake of their roots for winter use, are the Strasburg onion, the red Spanish *onion*, and the white. These are to be propagated by sowing their seeds in the latter end of February, in a dry, and somewhat sandy soil, yet rich: in about a month's time the plants will appear, and, in a fortnight after that, they will be forward enough for hoeing, which must be done with a very small hoe, cutting up all the weeds, and leaving the *onions* two inches asunder; this should be done in a dry season, and the ground will then be clear of weeds for a month. At the end of this time, they must be hoed again, and cut to three inches apart; and a month after this, to four inches, at which distance they will thrive well, and grow very large. Toward the latter end of July, the *onions* will have arrived at their full growth, which is known by their leaves hanging down, and shriveling; and they must at this time be pulled up, and spread on a dry place, and turned every day, to prevent their striking fresh roots; in a fortnight's time they will be dry enough to house, and should be wiped clean, and spread thin in an upper loft, or garret.

The differences between these species are not essential, they often degenerating into one another; and even the large Portugal *onion*, after a few years, with us, will lose itself so far that no one would imagine it came of that race. *Miller's* Gardener's Dict.

Welsh ONIONS, a sort of *onions* propagated by gardeners, for the use of the table in spring; they never make any bulb, and are therefore only to be eaten green in fallads. They are propagated by sowing their seeds toward the end of July in beds of a dry, but rich soil; and in three weeks after sowing, they will appear above ground: they must be kept carefully cleared from weeds. About October all their leaves die away, which has ocasioned some to think the whole plantation lost, and to dig up the ground for some other use; but if they are suffered to stand, they will shoot up again very strong in January, and from that time will grow very vigorously, and resist all weathers, and will be fit to draw for young *onions* in March, and are extremely green and fine, and more valued at market at that season than any other kind; but they are much stronger than any other *onions*, and have very much of the taste of garlick. Id. ibid.

ONION-*shell*, in natural history, a name given by authors to a peculiar kind of *oister*, which is of a roundish figure, and very thin, and transparent, and represents very exactly a piece of the peel of an *onion*. See OSTREA.

ONISCUS, in ichthyology, a name given by Athæneus, and others of the Greek writers, to the *accipenser*, or *sturgeon*. See ACCIPENSER.

ONISCUS is also the official name of the *whiting*. *Dale*, Pharm. p. 372.

ONISCUS, in zoology, is also a name used by some to express the common *millepedes*, called in English *wood lice*, and *sows*. *Aldrov.* de Inf. p. 632.

ONOBRYCHIS, *cock's-head*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the papilionaceous kind, and its pistil finally becomes a short pod, of a crested form, and in some species echinated; this contains a kidney shaped seed. To this it is to be added, that the flowers grow in a dense spike.

The species of *onobrychis* enumerated by Mr Tournefort, are these: 1. The great, vetch-leaved *onobrychis*, with bright red flowers, and an echinated fruit. 2. The great, vetch-leaved *onobrychis*, with pale red flowers, and echinated fruit 3. The great, vetch-leaved *onobrychis*, with echinated fruit, and with white flowers. 4. The stone *onobrychis*, with long, and narrow, vetch-like leaves. 5. The lesser *onobrychis*, with echinated fruit. 6. The lesser *onobrychis*, with a very large, and remarkably echinated fruit. *Tourn.* Inst.

ONOCENTAURUS, a fabulous animal, supposed to be a compound of a man and an ass. Ælian [a] speaks of *onocentaurs*. It was half man, and half ass, as the centaur was half man, and half horse [b]. — [[a] Lib. 7. cap. 9. [b] *Calmet*, Dict. Bibl.]

ONOCROTALUS, in zoology, the name of a very remarkable bird, commonly known among us by the name of the *Pelican*. It is of the size of a goose, or larger; and is of a greyish white all over, except that the neck looks a little yellowish, and the middles of the back feathers are blackish. The bill is remarkably long, and hooked at the end, and has under it a lax membrane extended also to the throat, and makes a bag or sack capable of holding a very large quantity. Its feet are web'd, as in the duck, and goose, all the toes being joined by the membrane. There is one very singular thing in this bird, which is, that its bones are solid, containing no marrow, and are all pellucid. *Ray's* Ornithol. p. 246.

ONOS, in ichthyography, a name given by some authors to the *æglefinus*, or common *haddock*. *Willughby's* Hist. Pisc. p. 170. See the article ÆGLEFINUS.

ONOS is used by Athæneus, and many other of the Greek writers, to the fish which we call the *hake*, the *asellus minor* of authors; called by Bellonius, Gesner, and some others, the *merlucius*.

ONYX, (*Cycl.*) in natural history, the name of a genus of the semipellucid gems; the characters of which are, that they have variously coloured zones, but none of red, these making them sardonyxes; and that they are formed of chrystal debased, but by a very small admixture of earth, and composed either of a number of flat plates, or of a series of coats made by incrustation round a central nucleus; the different coloured ones being covered with a coat of the basis or common matter of the stone, and separated from one another by, and alternately variegated with, thin veins of that matter, in form of other zones.

As there have been many disputes about what were properly the gems of the antients, the *onyx* has not been less perplexed than the rest. The characters here assigned them will distinguish them, however, from all other stones; and will not let the careful observer easily be deceived, when he sees a stone in its rough and native state; but they will not so well serve the less nice enquirer from being imposed upon in purchasing *onyxes* when cut and wrought. Our lapidaries seem to have had a design of banishing the distinctions of the agate and *onyx* out of the world; for as the zones are the most obvious character of the *onyx*, they have found an easy way to make pieces cut properly out of masses of agates resemble them. Agates, though never plated or formed of regular zones, are frequently veined in strait narrow lines, and a piece of one of these agates cut perpendicularly to the site of these veins, gives the very figure of the zones of an *onyx*. The white Gambay agate is what they usually choose for this purpose; such pieces of this stone as have the black dendritæ in them, when properly cut out from the rest of the mass, are their Mocoa stones; but other parts of the same stone, which have not these delineations, but have strait close veins are cut out in a proper direction, and sold for *onyxes*. These may always, however, be distinguished by their wanting the proper degree, purity, and transparence; and by this, that the common pale auricular *onyxes*, which are the kind these most resemble, have always a peculiar blueish cast, which is not found in these counterfeits.

We have four species of the *onyx* now in use among our lapidaries. The first is a blueish white one, with broad white zones. This was the true *onyx* of the antients, and is composed of a blueish white *onyx*, variegated with white and brown zones. It is sometimes found composed of flat and even plates of these, laid closely on one another, and sometimes is in form of a pebble, composed of a central nucleus of pure chrystal, or nearly pure, surrounded with those crusts which form the zones. It is very common in the East-Indies, and is found also in New Spain, and sometimes in Germany and Italy, tho' of much smaller value, and less brightness, hardness, and transparence.

The second is a very pure *onyx*, with snow white veins, which is exceeding bright and transparent, and tho' composed only of two colours, is inferior to very few of the *onyxes* in beauty. It is always found in the form of a roundish pebble, usually about the size of an egg, and composed of several coats of a blueish white, and a fine and pure white, laid evenly round a central neucleus of pure, but shattery chrystal; the whole is very bright, and the blueish part very little less transparent than pure chrystal; the nucleus is generally of an angular form, and the coats or zones being all exactly of the same shape, make a very beautiful appearance. It is found only in the East-Indies, and is very much esteemed in Italy, but with us is not so much regarded as it deserves.

The third species is the *jasponix*, which, see under its proper head.

The fourth is the brown *onyx*, with blueish white zones. This is a very clear and pure stone, but is so much less beautiful than the other kinds, that tho' very common in the East Indies, it is very seldom seen or regarded among us. *Hill's* Hist. of Fos. p. 490.

ONYX, in conchyliology, the name given by the curious to a species of voluta, found in cabinets, but never met with in that state on the sea shores. The true account of this is, that the shell in this elegant form owes its appearance to art, having been polished, and having had its outer coat taken off. With this outer coat which is of a dusky yellow, it is often kept in the same cabinet under another name, being then

then called by the French, the cierge, or wax-shell. See Voluta.

Onyx, in zoology, a name by which Pliny, and many other of the antient writers, have called the *solen*. See Solen.

Onyx *indicus*, in the materia medica of the antients, a term used by the Greek writers to express what is usually called *unguis odoratus*, or the sweet hoof. Some call it *onychus indicus*, as particularly Myrepsus in his antidote of fifty species. The same author mentions the *blatta bizantia*, and tells us that it is not the same thing with the *onyx indicus*, but that the Italians called by this name the *os nasi* or bone of the nose of the purple fish. What he means by this is probably the bony tongue of that animal, nature having given it such a weapon to pierce the shells of those fish on which it is to feed. We frequently find the chamæ, and other shell-fish, with holes bored through the upper shell as exact as if it were done with an instrument: this has been done by the purple fish, to get at the flesh of the animal within for food; and the bony tongue with which this fish performs this, is called by the Italians of those times *blatta Byzantia*. Actuarius translates the blatta Byzantia of all the earlier writers by the phrase *os nasi purpuræ*; and the interpreters of the Arabian writers give the same name to what they call *unguis odoratus*, or *onyx indicus*, for the Arabian name exactly expresses this.

The word *blatta* among the earliest Latin writers, means a bubble of mud. Paulus Ægineta quotes Festus for many instances of the word being used originally in this sense: after this, it became used for the grumes, or clots, into which the red part of the blood concretes, after it is out of the vessels; and, after this, it became a name for the sanies, or foul matter, concreting in lumps, when the purpura, or purple-fish, was exposed to the air. The purple colour was finally called by the same name, and from this, any thing dyed purple was said to be dyed with blatta. The blattæ of the Turkish dominions were the purple fish of that part of the world: these were more excellent than those of any other known part, and were therefore most employed. The word blatta Byzantia signifies no more than purpura Byzantina, and when the purple colour had been taken out, the tongues, or other parts of the shells of these fish, were used in medicine, under the same name of blatta Byzantia. Thus Myrepsus is found to be in the right. The *onyx indicus* of the Greeks was, however, very different. This, though it was also a shell, or part of a shell, was collected not at Constantinople, but in the lakes of the East-Indies. Dioscorides plainly makes it different from the purpura, by comparing the shell to that; he says, it is part of a shell fish, in many respects resembling the purpura. Some have supposed that Dioscorides understood the whole shell of the fish by the word *pama*, which he has used on this occasion; but this is not the case, for the Greeks had many other words to express a shell by, and no other author countenances the use of *pama* in that sense. Besides, Dioscorides says afterwards, that the whole shell of the fish which produced the *onyx* being burnt, had the same virtues with the shell of the purpura, and other the like fish. The Arabians seeing by this, that Dioscorides did not mean the whole shell by this word, have expressed his meaning by a phrase which signifies not a whole shell, but a fragment, or part of one. The word *pama* properly signifies operculum, and, as all the shell-fish of the buccinum kind, to which this purpura belongs, have opercula, or thin shells, to cover the orifice when the fish is retracted in, it is plain enough that the antients meant this by the word *pama*; and this they might very well call *onyx*, or *unguis*, from its being thin, and flat, and not unaptly resembling in size and shape, the human nail. This operculum, when taken from the purpura, as it seems to have been among the Romans, who had that fish from Constantinople, was properly called blatta Byzantia, being the only part of the fish used in medicine; but whether this, or the bony tongue, were so called, it is certain that this is no proper name for the true *onyx indicus* of the Greeks, which was not any part of the blatta, or purple fish; but, as Dioscorides expressly says, of another species of shell-fish, somewhat like it.

OOSCOPIA, Ωοσκοπια, in antiquity, a species of divination, wherein predictions were made from eggs. *Potter*, Archæol. Græc. l. 2. c. 14. T. 1. p. 319.

OOST, in husbandry, a name given by the people who manure hops, for the kiln in which they dry them after they are picked from the stalks. This is a square room, built up of brick, or stone, ten foot wide, more or less, and having a door on one side. In the midst of this room is a fire-place, about thirteen inches wide, and as much high; and, in length, reaching from the mouth so nearly to the back part of the kiln, that a man has just room to go round it. This fire-place is called a *herse*, and the fire is let out into the room by several holes in the sides, in the same manner as in malt-kilns. Five feet above this, is laid the floor on which the hops are to be laid to dry, and this must have a wall round it of four feet high, to keep the hops from falling out. At one side of the upper bed must be made a window by which to push out the hops as they are dried into a room prepared for them. The beds must be made of laths an inch square, placed at a quarter of an inch distance from one another, and supported by beams underneath. The hops are to be poured on this bed with a basket, till the whole is covered half a yard thick with them; when this is done, lay them even with a rake, and let a fire be made in the fire-place below. Some recommend a wood-fire, but experience shews that nothing does so well as charcoal; let the fire be kept at the mouth of the furnace, for the air will be carried all the way through; and thus let the hops lie, never stirring them till they are thoroughly dry; when they rattle under the rake, and the inner stalks are brittle, they are sufficiently dried, and are to be pushed out, and a fresh parcel laid in the *oost* in their place.

Some people dry their hops in a common malt-kiln, spreading them on a hair-cloth about six inches thick, and now and then turning them till they are all thoroughly dried, then laying them in a heap, till they are to be put in the bags. But both these ways are liable to some inconveniencies; the *oost* generally over-drys the under ones, by the time that the uper ones are dry enough; and the hair-cloth, and the turning in the other way breaks and shatters them, and spills many of the seeds. See Tin-*floor*.

OPAL (*Cycl.*) — The *opal* is a gem of a very peculiar kind, and has been esteemed by many, in all ages, of very great value; though, at present, it is of less price, in proportion to its size, than any other of the finer gems. The Romans esteemed it the fourth gem in value; and its singularity, as well as beauty, seem very well to entitle it to at least that rank; it is softer than any other of the gems, and is with difficulty polished to any degree of nicety. Its most frequent size is between that of a pea, and a horse-bean, but it is found as small as the head of a large pin, and up to the size of a wallnut. Its figure is very various, and uncertain, but it is never found in a columnar, or crystalliform state. Its most usual figure is an irregularly oblong, flatted at the bottom, and convex at the top, and dented with various sinuosities on the sides. There have been found some of the regular shape of a kidney, and others almost perfectly round, and, not unfrequently, it is met with in thin flat pieces. It is often found loose among the earth of mountains, sometimes on the shores of rivers, and not unfrequently bedded in the coarser kinds of jasper, ten or twenty *opals*, of different sizes and colours, being frequently found in one stone.

It is naturally of a smooth surface, and fine gloss, and many of the finest *opals* that have been seen, have been worn with their native polish. Its colour, as it appears in a fine specimen, is of so mixt a nature as not to be easily described, but is best expressed by comparing it to the finest sort of mother of pearl. It differs, however, greatly from that in its superior lustre and brightness, and in being so pellucid that one may see deep into the stone. As it is variously turned about, it shews the colours of all the other gems, yellow, red, blue, green, purple, and a milky grey. The last of these colours is the native dye of the stone, and it has many of the others in a superior beauty even to the gems to which they naturally belong, particularly the fire-colour of the carbuncle, which seems in the *opal* to lie deep in the body of the stone. It is the most difficult to counterfeit of all the gems; and this is done by a very fine, and well chosen piece of some pearly shell. It is sometimes found wanting one or more of the colours, and sometimes of a deep blueish black, with no other colour visible on changing the light, but a deep red, which is very strong and glowing, and makes it a very beautiful stone; sometimes it has also a general yellowish cast, and sometimes a greyish one, which greatly impair the reflexions of the other colours, and injure the stone.

It is found in Ægypt, and Arabia, and in some parts of the East-Indies, and in Europe. The oriental ones are the finest, but those of Bohemia are often very beautiful. *Hill's* Hist of Foss. p. 600.

Counterfeit Opal. To imitate this gem in natural crystal, use the following method: take yellow orpiment, and white arsenic, of each two ounces, crude antimony, and sal armoniac, of each one ounce; powder all these, and mix them well together; put this powder into a large crucible, and lay upon it small fragments of crystal, and, upon these, other larger pieces of crystal; fill up the crucible with these, and lute on to it another crucible inverted, with a hole at the bottom as big as a small pea; when the lute is dry, set the vessels in a quantity of charcoal in a large chimney, covering them up with coals to the middle of the upper crucible; so long as the materials fume out at the hole, keep up a strong fire; when that is over, let the fire go out of itself; and then unlute the crucibles; the greatest part of the crystal will be found tinged to the colours of various gems; not only the *opal*, which will be very fair, and beautiful, but the topaz, and ruby colour will be seen in others. *Neri's* Art of Glass, p. 119.

OPEN (*Cycl.*) — *Self*-Opens. See Self-*opens*.

OPERATION (*Cycl.*) — *Hermit*-Operation. See the article Stone.

OPHICARDELON, in natural hiftory, the name of a gem mentioned by Pliny, which, he fays, was a black ftone covered at top and bottom with white: this feems, without all doubt, to have been the *camea* of our jewellers.

OPHIDION, in ichthyology, the name of a fifh of the eel kind, and refembling the common eel, and conger, in fhape, but that it is fhorter in proportion to its thicknefs, and more flatted, and of a paler colour. It feldom exceeds eight inches in length, and the back is grey, and the fides of a bright filver colour. It is cloathed with fmall fcales, which are long and narrow, and are not placed like tiles hanging over one another, as in other fifhes, but only fcattered here and there, and laid in no order. The mouth is large, and the jaws are furnifhed with very fmall teeth, and, befide thefe, with three fmall eminences fet with the like teeth; the one on the roof of the palate, the others lower on each fide. The eyes are large, and it has one pair of fins near the gills. It is a very delicate fifh, and is caught in great plenty in the Mediterranean, and fold at Venice, and other places. *Willughby's* Hift. Pifc. p. 112. *Aldrov.* l. 3. c. 26. *Gefner*, p. 104.

The name *ophidion* is given by Artedi to a genus of fifhes, the characters of which are thefe: they are of the malacopterygious, or foft-finned kind; the body is oblong, and of a cylindric figure, and has three fins. The fpecies of this genus are properly only two, diftinguifhed by the cirri, or beards. The firft is the *ophidion* with four cirri growing from the lower jaw: this is the *ophidion* of authors. The fecond is the *ophidion* without cirri: this is found in the Baltic. *Artedi*, Gen. Pifc. 20.

OPHIOBORUS, in natural hiftory, a name given by the antients to a fpecies of carnivorous fly, which feeds on the bodies of beetles, or other flies, or on the flefh of dead ferpents. Its wings are of the colour of polifhed brafs, whence it was alfo called by the Greeks *chalcomuca*, the *brafs fly*.

OPHIOGLOSSUM, *adder's tongue*, in botany, a genus of plants, no part of the fructification of which is vifible, except the fruit. This is an oblong, double, or diftichous capfule, divided by a great number of tranfverfe articulations, into many cells, each of which, when mature, opens tranfverfely, and is found to contain a great number of fmall feeds of a fubovate figure.

Cafpar Bauhine defcribes what he calls three fpecies of this plant. 1. The common *ophioglofſum*, with a fingle leaf, of an ovated figure, having no vifible nerves, or veins in it, very thick and flefhy, and of a beautiful bright green. This fpecies is a native of England, and common in deep paftures. 2. The angular-leaved *ophioglofſum*. And, 3. The roundifh-leaved *ophioglofſum*. Mentzal defcribes three fpecies alfo befide the common one; but all thefe are only varieties of the common *ophioglofſum*, the capfule or fpike of which is often bifid, and the leaves vary greatly in length and breadth.

All Europe, fo far as yet known, affords only one fpecies of *ophioglofſum*; but, in America, are found two diftinct fpecies, befide the common European fort. 1. The reticulated, heart-fhaped-leaved, *ophioglofſum*. And, 2. The palmated *ophioglofſum*.

Tournefort makes eight fpecies of *ophioglofſum*, which are only the varieties of the common European kind, mentioned above. Vid. *Hill's* Hift. Plant p. 134, feq.

This is a fpring plant, and is only to be found in April, and May. It is not uncommon in wet meadows, and is eafily diftinguifhed among the other fpring plants by its fpike, or tongue.

It is efteemed one of the beft vulnerary herbs this nation produces; but it is more in ufe among the common people than in the fhops. They gives its juice internally, and ufe the herb bruifed, or an ointment prepared from it, with lard, or May butter externally at the fame time. *Dale's* Pharmac.

OPHIOMANCY, Ὀφιομαντεία, in antiquity, the art of making predictions from ferpents. Thus Calchas, on feeing a ferpent devour eight fparrows with their dam, foretold the duration of the fiege of Troy. And the feven quoils of a ferpent that was feen on Anchifes's tomb, were interpeted to mean the feven years that Æneas wandered from place to place before he arrived in Latium. Thus, Virgil. Æn. l. 5. v. 85.

Septem enim gyros, feptena volumina traxit.

The word is Greek, compounded of ὄφις, a ferpent, and μαντεία, divination. *Hofm.* Lex. in voc.

OPHIOMORPHITES, in natural hiftory, the name given by fome authors to the foffils called more ufually *cornua ammonis*; which are compofed of feveral wreaths, rolled in a fpiral form over one another, and refemble a fnake when rolled up. Thefe are found of prodigious fizes, fome not lefs than the fore-wheel of a chariot. They are evidently formed from fome fea-fhell, the fhelly matter remaining on fome of them, and all being compofed of feveral cells, communicating with one another by means of a fiphunculus, in the manner of thofe of the nautilus. See CORNU *ammonis*.

OPHIOPHAGI, in natural hiftory, a name given by fome to the *eagle vulture*, and fome other birds of prey which are fometimes feen to feed on ferpents.

Pliny gives the name *ophiophagi* to a certain people of Æthiopia, whom he defcribes as very barbarous and favage, going always naked, and feeding on ferpents, whence the appellation. Solinus, who generally copies Pliny, but imperfectly, has perverted his meaning ftrangely in this paffage, having placed the *ophiophagi* in Arabia Felix, inftead of Æthiopia.

OPHITES, the *ferpentine marble*, in the natural hiftory of the antients, a name given to fuch of the marbles as had their variegations not in form of veins, but of fmall fpots ufually of an oblong figure, and thence imitating in fome degree, fpots on the back of a ferpent.

The antients knew three fpecies of this kind, which they called the black, the white, and the grey *ophites*, and this laft alfo frequently *tephria*; and allowing thefe fpotted variegations to be the characters of an *ophites*, we have, befide thefe, two others known at this time.

As to the *ophitæ* of the antients, the uncertain accounts they have given us of them have been the occafion of many unlucky miftakes, about what they meant by the names. Some have imagined that they meant a black, others a white marble. A more accurate furvey of their works together, will fhew, however, that they, in reality, were very diftinct in their meaning, though they feem obfcure, becaufe fhort; but they ever diftinguifhed between their three *ophitæ*; and it is plain from them, that the black and white *ophitæ*, as they call them, were both marbles whofe ground was green, and only were diftinguifhed by their variegations, and their different degrees of hardnefs; and what they mean by the black and white, was only the black fpotted, and the white fpotted *ophites*. *Hill's* Hift. of Foff. p. 483.

Black OPHITES is a very beautiful, and confiderably hard marble, of a very fine green, aad elegantly variegated with fmall black fpots and irregular lines, and fometimes with an admixture alfo of white ones. Thefe are frequently feen together in the fame block, and make a fort of white fpotted, and black fpotted kinds; but the diftinctions of the antients were not founded only on thefe, but on the effential character, the hardnefs of the ftone, the white kind being greatly fofter, as we find by all their accounts.

The antients found this fpecies in Ægypt, and knew of it in no other place. We have it now in many parts of the world: the defarts of Arabia abound with it; it is common in the iflands of the Archipelago; and has often been found in Wales. *Hill's* Hift. of Foff. p. 484.

White OPHITES is alfo a very beautifully variegated mafs, of a fine and even texture, moderately heavy, and, when pure, is of a very elegant pale green, not unlike that of the malachites, and elegantly variegated with fpots, clouds, and lines, of a fine deep black, an extremely pale green, and often with very large variegations of pure white. It is very foft, and eafily fcratched, even with a pin, but is capable of a good polifh, and looks very beautiful and bright, when wrought.

The antients had it in great repute; it cut eafily, and without much trouble, was made into elegant veffels for their tables; and in Germany, it is ftill in common ufe on the fame occafions, and is by fome recommended as a medicine againft venemous bites. The antient writers have well diftinguifhed this from the black kind, not by its whiter fpots, which were common to both, though more frequent and numerous in this, but by its foftnefs. They had it only from Ægypt, but we find it in France, Italy, Germany, and fome other places.

Grey OPHITES, called alfo *tephria*, was not, like the other fpecies, diftinguifhed by its fpots, but by its ground colour, which is a very lively and beautiful afh-colour, or pale grey. It is a very fine, even, and fmooth marble, and is variegated with a multitude of black fpots of irregular figures; but, in general, all much of the fame fize, and that not exceeding the fixth part of an inch in length: it is confiderably hard, and takes an elegant polifh. The antients had this with their bafaltes from Æthiopia. Ægypt alfo afforded it, and does fo to this day: in Germany alfo we find it in large quantities. It has been celebrated from the earlieft times for its virtues againft venomous bites, and is in many parts of the world worn as an amulet, to this day.

The other two *ophitæ*, which feem not to have been known to the antients, are 1. A greyifh brown one, with green fpots. The ground of this is of a dufky afh-coloured brown, and the fpots are of a lively and beautiful green, ufually fmall, and of an oblong figure; and the whole is very hard, of an even ftructure, and capable of a fine polifh. It is frequent in Ægypt, and Arabia, and is faid to have been dug in England. The 2. is a pale grey one, with green fpots and veins. This is a fmooth and fine marble; its ground is a beautiful pale grey, in fome places flightly tinged with red, and in others approaching to white. Its ground has all thefe varieties in colour, fometimes in the fame, fometimes in different blacks, and it is variegated with a very beautiful pale green, difpofed with not much lefs variety, for it is fometimes in fmall fpots, fometimes in thin uneven veins, and fometimes in thicker. It is very hard, and capable of an elegant polifh. It is frequent in Germany, and tables are made of the larger pieces, and vafes of the fmaller ones. It is faid alfo to be found in England. *Hill's* Hift. of Foff. p. 486, feq.

OPHRIS, or OPHRYS, in botany, the name of a genus of plants, called in English *twyblade*, the characters of which are these: the flower, which has no perianthium, consists of five oblong petals. The nectarium is dependent, longer than the petals, bifid, and marked with a deticulation on each side of its base. The stamina are two very short filaments. The antheræ are erect, and covered by the inner margin of the nectarium. The germen of the pistil is oblong and contorted. The style adheres to the inner side of the nectarium. The fruit is an oval capsule, containing a multitude of dust-like seeds. Vid. *Linnæi*, Gen. Plant. p 434.

The species of *ophris* are; 1. The ovated-leaved *ophris*, or the common *twyblade* 2. The bulbous-rooted *ophris*. 3. The creeping-rooted marsh *ophris*. 4. The least, or triangular-leaved *ophris*. Vid. *Hill*'s Hist. of Plants, p 592.

OPILIO, in natural history, the name given to a peculiar genus of spiders. The distinguishing character of which is, that they have but two eyes. Their legs are usually very long, and their skin hard and firm. They do not spin webs like the common spiders, for the catching their prey. Their head seems to grow to the middle of their shoulders: their forceps is terminated by two claws like those of the leg of a crab. They differ from the common spider also, in the nature of their excrements; those of this kind being hard and solid, the others liquid.

Of these there are four principal kinds: 1. The grey crested *opilio*. This is the largest spider of this kind. Its body is greyish or brownish, and its legs very long and slender; and it has on the back part of the head, a sort of crest formed of a double row of spines, and there is a rhomboidal crown spot on the middle of the back. This species is common in the fields about August. 2. The redish brown not crested *opilio*. This is of a middling size, and has the longest legs of any kind. 3. The small wood *opilio*, variegated with black and white spots, with a very elegant crest. This is very small, and has a remarkably little head Its legs are remarkably long. It is found in woods in April. 4. The small scarlet spiders, commonly called the *tant*, or *taint*. This is supposed to be very poisonous. *Ray*'s Hist. of Insects, p. 29. See the article TANT.

OPIMATORES, among the Romans, military men, who had the direction and management of the provisions, and were to take care that the army wanted nothing. *Pitisc.* Lex. Ant in voc.

OPISTHODOMUS, ὀπισθόδομος, among the Athenians, the public treasury, so called from its being situated on the backside of Minerva's temple Here, besides other public money, a thousand talents were laid in store, against any very urgent occasion; but if any man expended them upon a trivial account, he was to put to death. Also the names of all that were indebted to the commonwealth, were entered in a register in this place. The tutelar gods of this treasury, were Jupiter Σωτὴρ, or the Saviour, and Plutus, the god of riches, whom they represented with wings, and placed next to the statue of Jupiter the Saviour; which was unusual in other places. *Petter*, Archæol. Græc. l. 1. c. 8 T. 1. p 31.

OPISTHOGRAPHUM, ὀπισθογραφὸν, among the antients, a waste book, or schedule, on which were writ, extemporary things that wanted to be revised and corrected afterwards. *Pitisc.* in voc.

The word is compounded of ὄπισθε, *i. e.* afterwards, or on the backside, and γράφω, I write; because it was writ over again on the backside of every page, which was left blank for that purpose.

OPIUM (*Cyl.*) — Dr. Charles Alston, professor of botany and the materia medica, in the university of Edinburgh, has given us a dissertation on *opium* in the medical essays of that place, vol. 5. art. 12. This gentleman is of opinion, that notwithstanding the authorities of Lemery, Savary, Monsieur de la Condamine, in the Mem. de L'Acad. des Sciences for 1732, mentioned in the Cyclopædia, all which would lead us to conclude we have nothing but the meconium, or the expressed juice or decoction of the plant, our *opium* is neither an extract, nor an inspissated expressed juice of poppies, but the milky juice drawn by incision from poppy heads. To shew this, the doctor, according to the directions of Dioscorides, on a dry day before noon, cut off the crown of white poppy heads, so as to avoid penetrating into the cavity of the fruit, and collected the milk with a silver spoon in a China cup. The juice being exposed to the open air, in a few days thickened to the consistence of *opium*, and was of a fiery, hot, bitter taste, and soporiferous smell, and more so than the common *opium*, of a dark yellowish brown colour on the outside, somewhat higher within, and appeared as if composed of drops: after ten years keeping, its colour and taste remained. This agreed with the account Bellonius, lib. 3. obs 15. gives of the best *opium*. That which was gathered from the papaver vulgare, or wild poppy, was somewhat of a lighter colour; but Dr Alston thinks this but accidental, as the milk soon turns black on the knife. He also slightly scarified some poppy heads after the Persian manner. When the juice was thickened, he scraped off the *opium*, and obtained more of it than by the other method. To procure the tear in its utmost perfection, he cut off the star from several heads, and bending them down, let the milk drop into a cup. It grew solid as *opium*, and being formed into a lump, appeared uniformly white; nor was there any difference in the juices of different poppies.

Secondly, the Doctor observes, that the extract and inspissated juice scarce any way resemble *opium*; nor is their taste and smell like it. The extract appears black when dried, and so does the juice, but when diluted, the first is brown, and the latter green. The extract is tough and adhesive, the juice rough and friable, and grows mouldy a day or two after expression. *Opium* may possibly be mixed with either of these; and the greenish brown *opium* may have some small portion of the juice in it. Its penetrating smell is certainly owing to the mixture of some aromatic substance.

Thirdly, *opium* contains more rosin than either the inspissated juice, or extract. One third of *opium* appears to be rosin, while the juice and extract scarce yield one tenth part.

Fourthly, if *opium* was not the tear of the poppy, there would be no occasion for sowing so many fields with poppies in Egypt, and other places. Nor would it be so powerful a medicine, for its anodyne virtues depend chiefly on the milky juice.

The objection drawn from the low price of *opium*, is of no force; for even in this climate, where the heads are small, the Doctor observes he could, in an hour, collect a dram of *opium* without the Persian knife, or that dexterity which is acquired by practice. From all these considerations he concludes, that the greatest part of *opium* is the tear of the poppy.

It has been controverted whether *opium* be got from the white or black poppy. Dr. Alston thinks it of no consequence, with respect to the medicine, which be chosen; the juice of both having the same effects.

As to the sophistication of *opium*, the Doctor is of opinion, that only an innocent liquid is mixed with it, or a milky juice of the same nature with that of poppies, otherwise it would not be so strong as what is made here. As the wild lettice, or *lactreca silvestris od re virosa*, C. B. *Pin.* 123. abounds with a milk of the same taste and smell with *opium*; it may possibly be mixed with it, and without detriment; since the milk of the common lettices is anodyne and somniferous.

Many learned men among the moderns, have been of opinion, that *opium* was the nepenthes of Homer. Dr. Alston forms some objections against this, and thinks that some of the antient physicians, who were neither strangers to Egypt nor Homer's works, would have made the discovery long before the sixteenth century.

Opium is acrid, bitter, and strongly odoriferous. On attentively tasting it, a nauseous bitterness is first perceived; then a pungent heat affects the tongue, next the palate, and last of all the lips. The heat continues some time, the bitterness longer, provoking a plentiful discharge of saliva. It also heats the nose, and produces an inclination to sneeze. *Opium* is certainly diaphoretic, and has stimulating qualities, which strongly refute the notion of its being refrigerating; it is certainly a hot medicine, tho' in many cases it diminishes preternatural heat.

Opium consists of five parts of gum, four of resin, and three of earth, not dissolvable either in watry or spiritous menstruums. Supposing that the resin of *opium* is as good, or as much wanted as the gum, or the mucilaginous part, brandy will be found the best menstruum.

Frider. Hoffman thinks the narcotic virtue of *opium* depends on its volatile sulphur, (*vaporosum sulphur*.) Geoffroy in his *Materia Medica*, will have this virtue owing to a thick rarefiable sulphur, (*sulphur crassum ad modum rarefcibile*) a kin to that of saffron, castor, &c. But Dr. Alston thinks both these opinions insufficiently supported. *Opium* is rather alcalescent than acescent, yet it is not an alcali. From the abovementioned gentleman's experiments, it seems that the solution of *opium* gave more appearances of an alcali, than of an acid; contrary to the account given by Geoffroy, Mat. Med. Tom. 2. p. 691. From these experiments it also appears, First, that the essential salt of *opium* is ammoniacal; Secondly, that *opium* contains a very small proportion of an acid; Thirdly, that it is astringent, or makes the same change on Chalybeats which vegetable astringents do.

The most active principles of *opium* are very fixed; for it keeps well, and, when forty years old, remains hard, solid, and retains its taste; and it seems that the practice of toasting *opium*, in order to correct it, by divesting it of its narcotic part, is of no service; and *opium* affords little or nothing by distillation.

Upon a chemical analysis *opium* yields phlegm, urinous spirit, oil, a volatile and a fixed salt, and some earth; but little of the virtues of *opium* can be investigated, or explained, from its analysis, since simples extremely different as to their effects on human bodies, afford the same principles on distillation, as Homberg has shewn by the analysis of the deadly night-shade, and cabbage. See Mem. de l'Acad. des Sciences. An. 1701. The curious may find the analysis of *opium* in the abovementioned dissertation by Dr. Alston.

The effects of *opium* on other animals are not much different from its effects on men. Dr. Alston put a few drops of a solution

lution of *opium* into a frog's ſtomach, and the circulation of the blood of the animal being examined by a microſcope, no alteration was perceived in the blood, as to its conſiſtence, colour of the ſerum, magnitude, figure, or colour of the red globules, but its velocity was ſurprizingly diminiſhed. In about half an hour, the blood regained its common celerity, and the frog its vigour. On giving the creature a ſecond doſe, the blood moved ſlower than it did the firſt time, and its velocity gradually decreaſing, ſtagnated firſt in the ſmaller, then in the larger veſſels, and in a quarter of an hour the frog expired. It is remarkable, that, notwithſtanding the diminution of the velocity of the blood, the pulſe was not leſs frequent, and that even when the circulation ſtopt in the foot, the pulſe remained viſible by an undulatory motion. On opening the frog, its ſtomach was found full of a clear mucus, tinged with the *opium*, and every thing alſo ſeemed perfectly natural. This experiment was repeated ſeveral times, with the ſame appearances.

A dog being killed by an injection of a ſolution of *opium* into his crural vein, on opening his thorax, the lungs were found ſound, but very ſmall, and white, without any blood in them. The heart was big, and all its great veſſels diſtended with blood; but nothing preternatural was obſerved in the brain or abdomen.

Opium, externally applied, is diſcutient, anodyne, and ſoporiferous, and has almoſt the ſame effects as when taken inwardly; but, that it can make any part inſenſible of pain is not evident. Wedelius declares he never could obſerve any ſuch effects. One inconvenience following the immoderate application of *opium*, mandragora, and hyoſciamus for pains of the eyes, taken notice of by Galen, is the mydriaſis, or a preternatural dilatation of the pupils. Mr. Ray gives a notable inſtance of this kind, ariſing from the application of a leaf of the deadly night ſhade to a cancerous ulcer a little below the eye. The uvea, in a night's time, entirely loſt its muſcular force, and was ſo relaxed, that the pupil, in the cleareſt light, remained four times bigger than that of the other eye.

Opium rather coagulates, than attenuates the blood. See Dr. Friend's Emmenolog. cap. 14. This favours what is affirmed by ſome authors, that the blood has been found congealed, or frozen, as they expreſs it, about the heart of thoſe who have been killed by *opium*. See Wedel. Opiolog. l. 1. §. 1. c. 5.

Uſe makes the quantity of *opium* ſafe, and even beneficial, which would otherwiſe prove poiſonous. Daily experience confirms this; and they who habituate themſelves to *opium*, find it as neceſſary as ſpirituous liquors to tiplers. A few grains will deſtroy a perſon unaccuſtomed to it, but ſome diſorders, as madneſs, enervate its force. Among the Eaſtern nations, a dram of *opium* is but a moderate doſe. Garcias mentions one who took ten drams every day, and tho' ſhe appeared ſtupid and ſleepy, yet ſhe diſputed very readily and learnedly on any ſubject. It is remarkable that, notwithſtanding this exceſſive uſe of *opium*, the Turks are generally long liv'd, if we credit Bellonius, lib. 3. obſ 14, 15.

The action of *opium* is very analogous to that of wine or vinous ſpirits; the good and ill effects of both differ little. See Wedelius in his *Opiologia*, and Geoffroy's materia medica. Platerus affirms that wine is narcotic, and Sydenham that *opium* is the moſt excellent cordial in nature.

The virtues of *opium*, internally taken, depend chiefly on its action on the ſtomach. There are many inſtances of terrible ſymptoms, and death itſelf cauſed by narcotics, before they went out of the ſtomach, and without inflaming it, or cauſing any viſible change in it, far leſs vitiating the maſs of blood; and alſo of the ſame ſymptoms being removed, and death prevented by vomiting. Dr. Alſton is alſo of opinion; 1mo. That the anodyne and hypnotic virtues of *opium* do not depend on its action on the brain or on the blood. 2do. That it affects firſt and principally the nerves to which it is applied; next ſuch as more immediately communicate with them; then thoſe which ſerve for ſenſation and voluntary motion; and laſt of all, by conſent the whole nervous ſyſtem. 3tio. That this impreſſion on the nerves differently affects the ſenſorium commune and the mind according to its degree, and the nature and function of the nerves primarily acted upon. 4to. That the primary or firſt obſervable effect of the mechanical impreſſion of the narcotic part of *opium* on the nerves, is the relaxation of their fibres. Now as this relaxation of the nerves, and conſequently of the moving fibres, demonſtrates *opium* to be more than a palliative remedy in a great many diſeaſes; ſo it is not difficult by it to account for its bad as well as good effects. For by relaxing to a certain degree, it may prove anodyne, cordial, diaphoretic, hypnotic, &c. or cauſe ſtagnations, deliriums, lethargies, apoplexies, and death.

It does not appear that *opium* rarefies the blood, or that the operation of this medicine depends on ſuch a rarefaction. If it were, it ſeems likely that bleeding might be a remedy for the ſymptoms occaſioned by the abuſe of *opium*; but ſome authors affirm that veneſection is mortal even the day after a narcotic has been taken. See Dr. *Alſton*, loc. cit.

We have an account in the Memoirs of the Academy of Sciences at Paris, of the death of a young man at Cairo, from his being decoyed into taking a very large doſe of this medicine. Among a number of young people in that city, who frequently drank together, there was one who always boaſted of his ſuperior power to bear a large quantity of liquor and his companions, determined to get the better of him for once, diſſolved, without his knowing of it, a dram of liquor in the liquor he was to drink; the conſequence was, that, inſtead of falling aſleep, as they expected he would, he fell into violent deliriums, and afterwards into a profound and dead ſleep.

The next morning his comrades went to ſee him, and triumph in their victory, but found him dying, looking livid, without pulſe, and with his mouth cloſed. They ſent for aſſiſtance, but in vain. After the death of the perſon, the body, arms, and thighs, became covered with livid tumors as big as the head of a young child, and theſe emitted an intolerable ſtench, almoſt as ſoon as the corpſe was cold. There is one very ſingular accident in regard to this caſe, which is, that this ſtench allured all the cats from the neighbouring houſes, who came with great eagerneſs, and were hardly prevented from devouring the body.

Dr. Smyth, while at Smyrna, took pains to obſerve, what the doſes of *opium* taken by the Turks, in general, were. He found that three drams in a day was a common quantity among the larger takers of it, but that they could take ſix drams a day without miſchief. A Turk eat this quantity before him, three drams in the morning, and three in the evening, with no other effect than its giving him great cheerfulneſs. But the taking it thus habitually greatly impairs the conſtitution; the perſons who accuſtom themſelves to it, can by no means live without it, and are feeble and weak; their legs are uſually thin, and their gums eaten away, ſo that the teeth ſtand bare to the roots; they are often alſo of a yellow complexion, and look much older than they really are. The Turkiſh meſſengers, when ſent upon buſineſs of haſte, always carry *opium* with them, and take largely of it when tired; they ſay it immediately gives them ſtrength and ſpirits to proceed, taken with proper precaution. Phil. Tranſ. N°. 223.

When *opium* affects the head, or lungs, by its volatile æthereal oil, or ſpirit, acids, eſpecially foſſile acids, are the proper correctors. And, when it produces ſickneſs, nauſeas, vomitings, ſpaſms, flatulent colic pains, and ſuch like ſymptoms, by the action of its ponderous, ſtimulating, and adheſive oil, the warmeſt alexipharmics muſt be uſed. *Morgan*, Mecan. Prac. Phyſ. p. 271.

Opium given too ſoon, to ſtop the operation of emetics, has been known to produce dangerous effects. See Medic. Eſſ. Edinb. Vol. 4. Art. 6. or its Abridgment, Vol. 1. p. 160.

The reſinous part of *opium* being noxious in Mr. Godfrey's opinion, he propoſes to make liquid laudanum, by digeſting an ounce and a quarter of *opium*, in half a pint of diſtilled water twenty-four hours, ſhaking the veſſel frequently; then filtres it, and adds three ounces of ſpirit of wine; after which, the other ingredients may be added at pleaſure. Miſc. vere util. p. 59.

OPIUM *Cyreniacum*, in the materia medica, a name given by ſome of the writers of the middle ages to *aſſa fœtida*. This was the *ſcordolaſaron* of the Greek writers of thoſe times, and was called *Cyreniacum* from the place whence it was principally brought. Aviſenna tells us, that, in his time, it was brought principally from Kirvan, and that is Cyrene.

OPLITODROMI, Ὁπλιτοδρόμοι, among the Greeks, a deſignation given to thoſe who run in armour, at the Olympic, and other games. *Potter*, Archæol. Græc l. 2. c. 21. T. 1. p. 442.

The word comes from the Greek ὅπλον, *armour*, and δρόμος, *a race*.

OPOBALSAMUM, (*Cycl.*) in the materia medica, a name given by ſome authors to the true *balſamum judaiacum*, or *balm of Gilead*. *Dale*, Pharm. p. 282.

OPOPIA, a name given by ſome anatomical writers to the bones which form the receptacle of the eyes.

OPORICE, a name given by the antients to a medicine compoſed of the autumnal fruits, and extolled for its great virtues againſt weakneſſes of the ſtomach and dyſenteries.

It was compoſed of five quinces with their ſeeds, as many pomegranates, a pint of ſervices, a pint of Syrian ſumach, and half an ounce of ſaffron; all theſe were put together into a gallon of muſt, and boiled over a very gentle fire to the conſiſtence of honey, with great care to avoid burning. Vid. *James* Med. Dict. in voc. & *Pliny*, l. 24. c. 14.

OPOS, a word uſed by the old medical writers, to expreſs the juices of plants, whether flowing ſpontaneouſly, or by means of inciſions. It is uſed by Hippocrates to expreſs the juice of ſilphium, which was called ſimply the juice, by way of eminence, as we call the quinquina bark ſimply the bark. Others have made it ſignify the juice of the fig-tree, and the caprificus, which they had in frequent uſe to curdle their milk.

OPOSSUM, or POSSUM, in zoology, the name of a very remarkable American animal, deſcribed by various authors, under the names of *maritacaca*, *carigoi*, *ropoza*, *carigueya*, *jupatuma*, *tlaquatzin*, *ſarigoi*, and *ſemivulpa*.

It is a creature of the ſize of a large cat. Its head is ſhaped like that of the fox; its noſe ſharp, and its upper jaw longer than the under; its teeth are ſmall, but like thoſe of the fox

and it has two long ones, like the hare, in the front of the mouth; its eyes are very beautiful, small, round, and vivid; its ears long, smooth, and very soft, placed erect, like those of the fox, and very thin and transparent. It has black whiskers, like those of a cat; and has other hairs of the same kind on the other parts of its face, and over its eyes; its tail is round, and a foot long, and is of great service to it, as it uses it to twist round the branches of trees, hanging itself to them by that means. The tail is hairy near the insertion, but naked all the other part, and is partly black, partly of a brownish white; its hinder feet are considerably longer than the fore ones, and each has five toes; they much resemble hands, and the nails are white and crooked, the hinder one being as in the monkey kind, the longest. Its head, and legs, as Hernandez observes, something resemble those of the badger. It has a broad, longitudinal, black streak, on the face; it is of a blackish colour with a mixture of a brown and grey on the back and sides, and has somewhat of a faint yellowish cast on the belly. *Ray's* Syn. Quad. p. 183.

What distinguishes this creature, however, from all the other animals of the world, is, that it has a bag or pouch into which it receives its young as soon as deliver'd; this is a sort of open uterus, and is placed under the belly near the hinder legs; in this the young are shelter'd till they are able to shift for themselves, and when they begin to be strong enough they frequently run out and return in again. The creature is of a stinking smell like our fox or martin. It feeds on sugar canes, and some other vegetables; but not wholly on these, for it frequently preys on birds which it catches on the trees, and often plays the fox's trick of stealing poultry.

The *Opossum* has been called *Marsupiale* by some authors, from the *Marsupium* or pouch for the receiving its young. This pouch is a membranous body, not very thick, though consisting of several coats. It has four pair of muscles, serving to contract and distend, as also to open and shut it at the mouth, and there are two bones in this part of the body peculiar to this animal, and serving only for the insertion of these muscles. The pouch itself is to be rang'd among the vesiculous parts of the body, which seem to be part muscles, part glands, and to perform the office of both motion and secretion. The hollow part of this pouch is lightly colour'd with hairs, but these are not placed so thick but that the skin is seen between them. These hairs are usually matted together in several places with a tough, yellow, and glutinous matter arising out of several glands there. This substance is of a very nauseous and offensive smell. Mr. Ray, and others, have observed that this animal, while alive, stinks like a pole-cat, or even worse than that animal. This stink is principally owing to the matter contain'd in this bag; and yet so nearly is this matter ally'd to that contain'd in the scent-bag of the civet-cat, and other animals, that when exposed to the air for some days, it loses its offensive smell, and becomes a very grateful perfume like them. The same observation holds good of the scent bag of our weazel, and pole-cat, which (particularly in the last animal) are very offensive while fresh, but when exposed to the air and dry'd, become only a perfume resembling that of civet.

John Faber relates out of Lerius, that the *opossum* or *serigoi* stinks so that the barbarous Indians refuse to eat it; but that if the kidneys be taken out, the stink goes off in a great measure, and the creature becomes eatable, and his flesh very well tasted; but it is very probable that Lerius, who had seen the operation performed, but examined only in a cursory manner, mistook the seat of the offensive smell, and that the person who performed it, cut deeper than he was aware, and took out this bag or pouch as well as the kidneys. The kidneys, and the fat about them, have no ill smell at all.

The pouch of the *opossum* has, beside its glandular coat, a muscular one, which serv'd to contract or distend the whole substance of it together, as its muscles did its particular parts; beside this, also, it has a vascular coat, in which the blood vessels are dispofed in very great abundance.

The male *opossum*, as well as the female, has this kind of pouch under its belly, and takes upon himself, at times, the care of carrying and preserving the young in case of any impending danger. Phil. Trans. N°. 239. p. 123.

OPTIO, among the Romans, an assistant or lieutenant belonging to every centurion.

They were called *optiones* from *opto*, I choose; because it was in the option of the centurion to choose whom he pleased for this employment; though at first it was otherwise, the *optio* being chosen by the tribune or chief commander of the legion. *Pitisc.* in voc.

The *optiones* were not peculiar to the camp, but were used also in many other offices of life. id. ibid.

OPULUS, the *water-elder*, in botany, the name of a genus of trees, the characters of which are these: The flower consists of only one leaf, but puts on a various form in the different ones. Some are rotated and pierced at the bottom by a pistil; these are barren. Others are hollowed into the shape of a basin, and pierced in the same manner at their bottom by the pointall of the cup: In these the cup finally becomes a soft juicy berry, containing a flatted and heart-fashion'd seed. See Tab. 1. of Botany, Class 20.

The species of *opulus* enumerated by Mr. Tournefort, are these: 1. The common *opulus* or *water-elder*. 2. The *opulus* with globose flowers. *Tourn.* inst. p. 607.

OPUNTIA, in botany, the name of a large genus of plants, the characters of which are these: the flower is of the rosaceous kind, or consists of several leaves disposed in a circular form. The cup, after the flower is fallen, becomes a seed-vessel of a fleshy substance, umbilicated, and unicapsular, fill'd with seeds usually of an annulated appearance.

The species of *opuntia* enumerated by Mr. Tournefort, are these: 1. The common *opuntia* or Indian fig. 2. The middle seed *opuntia*, with oblong leaves. 3. The *opuntia* with small roundish and compressed leaves. 4. The largest *opuntia* with long, broad, and thick leaves. 5. The smallest, round-leaved, Indian *opuntia*. 6. The small American *opuntia* with long and very slender spines. 7. The little, narrow-leaved, American *opuntia*. 8. The tall tree *opuntia* of America, with cereus leaves, and white flowers. 9. The tall tree *opuntia* of America, with articulated leaves and yellowish flowers. See Tab. 1. of Botany, Class 6.

We have several species of this plant, propagated in the gardens of the curious; they are all early raised by cutting off their branches at the joints during any of the summer months; these cuttings are to be laid by for a fortnight, in a dry, warm place, that the wound may heal up, otherwise they are very subject to rot, as are also all the other succulent plants. The proper place for planting these, is one third part common pasture land, one third sea land, and one third more of an equal mixture of lime rubbish and rotten tanner's bark. This mixture should be made three or four months before it is to be used, and the larger stones and clods separated, and laid at the bottoms of the pots, and the rest filled up with the finer part; the cuttings are to be planted in these pots, which are then to be plunged into a hot bed of tanner's bark, where they must be gently watered, and when they begin to shoot they must have as much air as possible; and, finally, removing them into the stove, they must be placed near the glasses, and have as much air as may be: they may be exposed to the open air in the summer months, but they succeed much better when they are kept continually in the stove. *Miller's* Gard. Dict.

ORACH, *atriplex*, in botany. See ATRIPLEX.

Stinking *orach* is a powerful medicine. The very smell of it will sometimes recover patients out of hysteric fits, when all the common means fail; and a decoction of the plant is an excellent medicine in the same cases. A decoction of it, made very strong, and given in a glyster, in hysteric cases, is also excellent; and a conserve of the leaves, one of the best forms it can be given in, has the same virtues in a very high degree, alone; and is a good medium to bring other medicines into the form of an electuary for the same purposes. A syrup of it is sometimes kept in the shops, and is not without its merit, though a great deal of the virtue of the plant be lost in such a form.

ORANGE, *aurantium*, in botany, the name of a genus of trees, the characters of which are these: the flower is of the rosaceous kind, being composed of several petals, arranged in a circular form; the pistil arises from the cup, and is surrounded by a number of little leaves, which terminate in the stamina. This pistil finally becomes a fruit of a roundish figure, covered with a thick and fleshy rind, and divided within into several cells, which are full of juice and vesicules, and contain several callous seeds. To this is to be added, that the leaves are heart-fashioned at the bottoms.

The species of *orange*, enumerated by Mr Tournefort, are these: 1. The common sweet *orange*. 2. The common-sharp-tasted *orange*. 3. The winter *orange*, with a less juicy fruit. 4. The sharp-tasted wild *orange*. 5. The *orange*-tree with curled leaves. 6. The stellated rose-*orange*. 7. The variegated *orange*. 8. The variegated, narrow-leaved *orange*. 9. The corniculate *orange*. 10. The narrow-leaved corniculate *orange*, with smaller fruit. 11. The striated *orange*. 12. The foetiferous *orange*. 13. The manyfold foetiferous *orange*, with one fruit, including two or three others. 14. The Lisbon *orange*. 15. The China *orange*. 16. The large-fruited *orange*. 17. The manyfruited *orange*. 18. The *orange* with very narrow spear-pointed leaves. *Tourn.* Inst. p. 620.

ORANGE-*flowers*. These flowers are very justly esteemed one of the finest perfumes. The water distilled from them is accounted stomachic, cordial, and carminative. Some also speak of it as a sudorific.

There are a very great variety of *orange*-trees in the gardens of the curious. The manner of raising them from seeds is this: When you purpose to raise stocks for buding, they should be raised from citron seeds, taken out of the rotten fruit in spring; for the stocks of this kind are preferable to any other, both for their quickness of growth, and their readily taking buds either of *oranges*, lemons, or citrons.

A good hot bed must be prepared, either of horse dung or tanners bark. The last, where it can be had, is much the best;

beſt; the ſeeds muſt be ſown in pots of rich earth, and theſe, when the bed is of a due temper, muſt be plunged into it. The pots muſt be watered frequently, and the glaſſes of the hot-bed ſhaded with mats in the heat of the day, and at times raiſed to give air.

The ſeeds will come up in three weeks, and a month after this the plants will be fit to tranſplant into ſingle pots. The bed muſt be now renewed, and ſome pots of about five inches over at the top, muſt be filled half full with freſh earth, mixed with very rotten cow-dung Place one plant in the middle of each of theſe pots, and then fill it up with the ſame earth; then place theſe pots in the new hot-bed, and water the plants every day. By July, the plants will be two foot high, and muſt then be hardened by degrees to the air, by raiſing more and more the glaſſes of the hot bed. In September they muſt be taken into the greenhouſe; in the winter ſeaſon they muſt have frequent ſmall waterings, and in ſpring their heads muſt be waſhed, to cleanſe them from filth. In ſpring, they muſt have again a gentle hot-bed, but in June they muſt be hardened again; and in Auguſt they will be fit to bud.

At this time you are to make choice of cuttings from very thriving and fruitful trees; chuſing ſuch buds as are round. When the ſtocks are budded, they muſt be removed into the greenhouſe, to ſhelter them from wet, turning their buds from the ſun, but letting them have as free air as poſſible, and refreſhing them often with water. They muſt remain in the greenhouſe all winter, and in the ſpring muſt have another bark hot-bed; then cutting off the ſtocks about three inches above the buds, obſerve to give them as much water as they require.

The buds with this management will be by July three feet high, and they muſt then be hardened by degrees, that they may bear the greenhouſe in the winter; and as this will be a ſufficient height for the ſtems, it is proper at this time to ſtop the leading branch to force out lateral ſhoots. This firſt winter they will be tender, and muſt be taken great care of, and after this they require no more care than other full grown trees.

It is a regular and certain way of ſupplying a greenhouſe with *orange*-trees, but there is a much more expeditious one, which is the purchaſing ſuch trees as are brought over every year from Italy. Theſe are as large when we receive them, as thoſe of our own produce will be in ten or twenty years growth; and tho' they have but ſmall heads then, will be brought to have very good ones in three years, and to produce very fine fruit.

In the choice of theſe trees, thoſe which have two buds in ſtock are preferable to thoſe which have only one; and the ſtraitneſs of the ſtem, freſhneſs of the branches, and plumpneſs of the bark, are greatly to be regarded. When you have purchaſed a proper number of theſe trees, each of them is to be ſet in a tub of water, with its head and half its trunk above the ſurface; they are to ſtand in this three days, then they are to be taken out, their roots picked, and bruſhed clean, and the tops of the branches cut off, and they are to be planted ſingly, in pots juſt large enough to contain their roots, in a mixture of freſh earth and rotten cow-dung. Theſe are to be ſet in a moderate hot tanners bark-bed, and ſome potſhreds muſt be always put at the bottom of the pots, to keep their holes from being ſtoped, and give a free paſſage to the water. They are to be moderately watered at proper times, and by the month of June they will ſhoot out pretty long ſhoots, which muſt be ſtoped, in order to produce the lateral branches. They muſt now be hardened by degrees, and in the middle of July muſt be brought into the open air, in ſome warm ſituation, defended from winds and from the too great heat of the ſun. In September they muſt be removed into the greenhouſe, and watered gently during the winter. In the ſucceeding ſummer, the branches muſt be ſtopped from growing to their lengths, to furniſh a good head; and they muſt be frequently watered. And after this, they will require no farther management, but to be new potted every year; which ſhould be done in April, and the earth prepared for it a year beforehand, of cow-dung and freſh earth. The roots ſhould be ſoaked a quarter of an hour in water, and afterwards ſcrubed very clean, before they are put into the new pot.

If old *orange*-trees have bad heads, the way to mend them is to cut them moſtly off, and proceed with them in the ſame manner as with the trees brought from Italy.

All *orange*-trees require frequent waterings, but theſe ſhould not be large; there muſt always be a paſſage for the water to run off at the bottom of the pot or tub; they muſt have as much freſh air in winter, as the ſeaſon will allow, and they ſhould not be placed too near each other in the greenhouſe. In ſummer they ſhould be placed where they may have the morning and evening ſun, without too much wind; and they ſhould not be houſed till October. The ſhaddock and citron are much tenderer than the *orange*, and ſhould therefore be houſed ſooner.

In the Philoſophical Tranſactions, Nº 114, there is a very remarkable account of a tree ſtanding in a grove near Florence, having an *orange* ſtock, which had been ſo grafted upon, that it became in its branches, leaves, flower, and fruit, three-formed; ſome emulating the *orange*, ſome the lemon, or citron, and ſome partaking of both forms in one; and what was very remarkable, was, that theſe mixed fruits never produced any perfect ſeeds; ſometimes there were no ſeeds at all in them, and ſometimes only a few empty ones.

The ſeeds of the *orange* kind ſeem different in their nature from thoſe of all other plants In the generality of others, the ſeed is only a ſort of nidus, and bed of a nouriſhing matter, for the young plant contained in ſome one part of it, and called the plantula ſeminalis; and however minute the ſeed itſelf may be, this plantula is but a very ſmall part of it: but the ſeeds of the *orange*, though contained in the inſide of a pulpy fruit, and in all reſpects, ſeeming of the nature of the common ſeeds, yet, when examined nicely, are found to contain, not a ſimple plantula ſeminalis, but each of theſe ſeeds or kernels, contains within it another compleat ſeed. Both in the *orange*, and lemon kinds, on opening what we call the ſeeds, when the ſkin, or membrane, is ſtripp'd off, there are frequently found two ſeeds encloſed in that membrane, that is, under the ſkin, and without ſide of the kernel, there is a ſmall ſeed, the like of which does not appear in the ſeed of any other fruit.

It is true, indeed, that in hazel nuts, as alſo in almonds, and in peach and apricot kernels, we often find a double ſeed, or kernel, but then each of them is ſeparately encloſed in its own membrane, and has no communication with the other, but is only placed in ſimple contact with it; and each has its diſtinct ſtalk, or ſtring, by which it ſeverally receives its nouriſhment; and, in theſe, the containing of two kernels ſeems only an accident, a kind of ſuperfœtation, as in the twin births of animals, which, naturally, bear only one.

When one of the *orange* or lemon ſeeds is ſtripp'd of its outer membrane, there appears a little ſtring, which lying under it, cauſes a protuberance in the firſt ſkin; and from this ſtring not only the ſeed, but the plant within it receives its nouriſhment; and the firſt and hard ſkin, which is eaſily ſeparated, ſeems only given to it for the defence of the inward parts; whereas nuts, almonds, peach-ſtones, and the like, have a much harder and firmer coat given them for the ſame purpoſe. The ſtring which appears through the firſt membrane extends its ſmall veſſels alſo through the ſecond membrane near the ſeat of the plantule; but theſe are ſo extremely fine, that we loſe them before they enter it, no microſcope being able to ſhew them farther than where they grow extremely ſmall, and fine, near the entrance into this part. It is an amazing thought, but it is alſo an evident truth, that this ſmall ſtring, which runs in this manner under the coat of this ſeed, contains in it as many diſtinct veſſels as are to be found in a full grown *orange*-tree; for if all theſe veſſels were not in the young plant, while involved in its matrix, whence ſhould they come afterwards? When this ſtring is cut tranſverſely, and examined before a good microſcope, ſomething of this appears, for there are ſeen in it the ſections of ſeveral veſſels, and the ſmall quantity of pulpy matter between them is encloſed in a ſeemingly thick and tough membrane, together with them, in order to keep the whole together: if the ſeed, or kernel, be itſelf cut acroſs, it appears to be only a congeries of a great number of globules of a ſoft matter, preſſed together. Within this ſeed thus cut, and under all its membranes are ſeen the two regular, and perfect ſeeds, lodged together, and not ſeparated by any membrane, as the accidental double kernels of nuts, &c. always are; ſometimes, indeed, there is only one ſuch obſerved, and ſometimes there are three. Theſe are not always of the ſame ſize, but one is often larger than the others. Each of theſe is, however, a true perfect, and diſtinct ſeed, and is divided naturally into two lobes, and theſe ſeem only to have been united at firſt, juſt where the young plant lies, ſo that this whole kernel ſeems to have been deſtined by nature for no other end, but to foſter and cheriſh the young plant, till it become able to ſhoot up and live above ground. In the heart of this inner ſeed is found the plantula ſeminalis, which is not larger than a ſmall grain of ſand, to the naked eye. The wonderful conformation of this ſtructure, cannot but ſtrike any one who is uſed to examine ſeeds, with great amazement. It is plain that the ſeed contained within the other ſeed, can only receive its nouriſhment from the veſſels contained in the ſtring above deſcribed But it is amazing, that theſe ſhould not be, as uſual, immediately diſtributed from that general cord, or congeries of them, to the ſeed itſelf, but to another that is the center ſeed, and can only come to the inner ſeed, after having paſſed thro' this, and been in it devaricated into other veſſels too fine for the eye to trace.

Signior Franciſco Lana, in his prodromus to ſome philoſophical diſcoveries, tells us, that there is a way of producing *oranges*, without ſowing or planting the trees, only by infuſing the flowers in oil of almonds; for that this oil will, every year afterwards, at the proper ſeaſon, produce both flowers, and ripe *oranges*. See the whole proceſs at large, under the article FRUITS, as atteſted by the author and his friends.

Sea ORANGE, in natural hiſtory, a name given by Count Marſigli to a very remarkable ſpecies of ſea plant. It is tough and firm in its ſtructure, and, in many things, reſembles the com-

common fucus; but, instead of growing into the branched form, the generality of those plants have, it is round and hollow, and in all respects, resembles the shape of an *orange*. It has, by way of root, certain very fine filaments, which fasten themselves to the rocks, or to shells, stones, or any thing else that comes in the way. From these their grows no pedicle, but the body of the *orange*, as it is called, is fastened by them to the rock, or other solid substance. The *orange* itself, is usually of about three or four inches in diameter; and while in the sea, is full of water, and retains this when taken up. In this state, it frequently weighs a pound and an half, but when the water is let out, and it is dryed, it becomes a mere membrane, weighing scarce any thing. It is best preserved, by stuffing it full of cotton, as soon as the water is let out of it, and hanging it up to dry in this form. Its surface is irregular and rough, and its colour a dusky green on the outside, and a clearer, but somewhat bluish green within; and its thickness is about an eighth part of an inch. When viewed by the microscope, it is seen to be all over covered with small glandules, or indeed, composed of them; for they stand so thick, one by another, as to leave no space between, and seem to make up the whole substance: so that it appears very like the rough chagrin skin used to cover toys. These are all so many hollow ducts, thro' which the sea-water finds a passage into the globe formed by this skin, and by this means it is kept always full and distended; on cutting it with a pair of sciffars, the water immediately runs out, and the skins collapse: but there is something farther remarkable, which is, that the whole substance, near the wounded place, is in motion, and seems as if alive, and sensible of the wound. The glandules are found full of water, and resembling small transparent bottles; and what goes to the structure of the plant beside these, is an assemblage of a vast number of filaments, all which are also hollow, and filled with a clear and transparent fluid.

There is another plant of this kind, described by Count Marsigli, Triumfetti, and others, and called the *ramose*, or branched *orange*. This is very much of the nature of the former plant, but instead of consisting of one round globule, it is formed of several oblong ones, all joined so together, that they represent the branches of some of the fucus's, but that they are shorter; and these are all hollow and full of water, in the same manner as the single globes of the common kind. This has, by way of root, certain fine and slender filaments, which fasten it to the stones or shells near which it is produced; and it is of a dusky greenish colour on the surface, and of a fine bluish green within. The surface viewed by the microscope, appears rough, as in the other, and the glandules are of the same kind, and are always found full of a clear water. *Marsigli*, Hist. de la Mer. p 81.

ORANGE-*dew*, a sort of dew which falls in the spring-time, from the leaves of *orange* and lemon trees, and is extremely fine and subtile. Mr. De La Hire observing this, placed some flat pieces of glass under the leaves to receive it, and having thus procured some large drops of it, was desirous of finding out what it was. He soon found that it was not a merely aqueous fluid, because it did not evaporate in the air; and that it was not a resin, because it readily, and perfectly mixed with water: it was natural here to suppose it a liquid gum; but neither did this, on examination, prove to be the case; for being laid on paper, it did not dry as the other liquid gums do. Its answering to none of these characters, and its being of the consistence of honey, and of a sweet-sugar-like-taste, gave a suspicion of its being a kind of manna; and whatever in the other tryals had proved it not a resin, a gum, &c. all equally tends to prove that it is this substance.

ORARIUM, in ecclesiastical writers, the same with *brandeum*. See the article BRANDEUM.

ORATORIO, in the Italian music, a sort of spiritual drama of dialogues, containing recitativos, duettus, trios, ritornellos, chorusses, &c.

The subjects of these pieces are usually taken from the Scriptures, or from the life of some saint, &c.

The music for the *oratorio* should be in the finest taste, and most chosen strains. These *oratorios* are greatly used at Rome in time of lent; and of late in England.

ORBICULAR *leaf*, among botanists. See LEAF.

ORBICULARE *os*. See the article OS.

ORBICULARIS, (*Cycl.*) in anatomy, a name given by Riolanus, and some others, to the muscle called by Albinus *orbicularis oris*, and by Cowper and others, *constrictor labrorum*.

ORBICULARIS, in botany, a name given by some authors to the *artanita*, or *cyclamen*, called in English *sow bread*. Ger. Emac. Ind. 2. See CYCLAMEN.

ORBICULARIS *intestini*, in anatomy, a name given by Vesalius, and some others, to the muscle now known by the name of the *sphincter ani*.

ORBIS, in zoology, the name of a genus of fishes, of which there are a great many species: that, however, which is usually meant by the word *orbis* above, is the species called *orbis primus*, by Rondeletius, and *orbis ægyptiacus* by Salvian, because frequently caught in the ostia of the Nile. Excepting the tail, this fish is of a round figure. It has no scales, but is covered with a firm and hard skin all over, full of small prickles, which render it very rough. Its mouth is small, and has four broad teeth. It has only one hole on each side for its gills, and a fin under each. It has another fin near the tail on its under part, and another answering to it in its upper. The tail is one broad and flat fin. It is not eatable, for the whole fish is head, or if you would rather call it so, belly. *Willughby's* Hist. Pisc. p. 143. See Tab. of Fishes, N° 18, 63.

There is an opinion, that when this fish is dryed and hung up by the tail, it will always turn its mouth to that quarter from whence the wind blows.

The other species of this genus are, the *orbis lagocephalus*, *orbis scutatus*, *orbis muricatus*, *orbis ranæ rictu*, *orbis spinosus Clusii*, *orbis muricatus alter Clusii*, and the *orbis oblongus testudinis capite*. *Rondelet*, *Gesner*, *Aldrovand*. and *Salvian*.

ORBIS *magnus*, in astronomy, the *orbit* of the earth in its annual revolution round the sun.

ORCHESOGRAPHY, the art of noting all the steps and motions used in dancing. See DANCE, *Cycl.*

ORCHIS, in botany, the name of a genus of plants, the characters of which are these: the flower is of the polypetalous anomalous kind, consisting of six leaves irregular in shape and size. The five upper of which are so disposed, as in some degree, to resemble a helmet. The lower leaf is of various shapes in the different species; it has usually a head, and often a tail, and resembles the body of a fly, a bee, a man, or other animal. The cup of the flower finally becomes a fruit, which is pervious by three fenestræ, to each of which there adheres a valve. The seeds are extremly small, and resemble a fine dust. To this it is to be added, that the roots are fleshy, with fibres propagated from them, and are in some species roundish, and resemble the testicles of an animal, and in others divided into several segments, resembling a hand and fingers. See Tab. 1. of Botany, class 11. *Tourn.* Inst. p. 431.

The species of *orchis*, enumerated by Mr. Tournefort, are these: 1. The broad-leaved great *orchis*, with a gaping hood. 2. The smaller-flowered broad-leaved *orchis*, with a gaping hood. 3. The broad-leaved *orchis*, with a compact spike of flowers. 4. The narrower-leaved *orchis*, with a gaping hood. 5. The great soldier *orchis*. 6. The middle soldier *orchis*. 7. The lesser soldier *orchis*. 8. The mountain soldier *orchis*, with a red conglomerated spike. 9. The tall meadow soldier *orchis*, with variegated flowers. 10. The lower meadow soldier *orchis*. 11. The sweet-scented purple mountain *orchis*. 12. The sweet-scented dusky purple *orchis*. 13. The globular-flowered *orchis*. 14. The dwarf alpine mossy-leaved *orchis*. 15. The common male *orchis*, with spotted leaves. 16. The common male *orchis*, with shorter spotted leaves. 17. The common *orchis*, with drooping leaves, not spotted. 18. The common *orchis*, with drooping plain leaves, and with small white flowers. 19. The common female *orchis*. 20. The common female *orchis*, with rose-coloured flowers. 21. The female *orchis*, with white and changeable-coloured flowers. 22. The common little male *orchis*, with spotted leaves. 23. The male man *orchis*. 24. The female man *orchis*. 25. The monkey *orchis*. 26. The male Portugal man *orchis*, with an aromatic smell. 27. The Portugal man *orchis*, with a small green flower with a purple edge. 28. The bearded or goat *orchis*, with short and broad leaves. 29. The goat *orchis*, with longer and narrower leaves. 30. The smaller goat *orchis*. 31. The smaller goat *orchis*, with a purple spike. 32. The common purple spiked stinking *orchis*. 33. The white sweet-scented *orchis*, with spiral flowers. 34. The two-leaved *orchis*, with very broad leaves. 35. The narrower-leaved bifoliate *orchis*. 36. The smaller bifoliate *orchis*, with white flowers, with long spurs. 37. The greater trifoliate *orchis*. 38. The smaller trifoliate *orchis*. 39. The butterfly *orchis*, called by some the *frog orchis*. 40. The greater bee *orchis*, with the upper leaves white and purple. 41. The bee *orchis*, with greenish flowers. 42. The bee *orchis*, with ferrugineous flowers. 43. The bee *orchis* with blue flowers. 44. The bee *orchis*, with spotted flowers. 45. The bee *orchis*, with white flowers. 46. The bee *orchis*, with wholly purple flowers. 47. The bee *orchis*, with variegated flowers. 48. The greater fly *orchis*. 49. The lesser fly *orchis*, with green wings and a green head. 50. The yellow fly *orchis*. 51. The narrow-leaved *orchis* 52. The *orchis* resembling an expanded butterfly, with green flowers. 53. The butterfly *orchis*, with spotted leaves. 54. The narrow-leaved white flowered butterfly *orchis*. 55. The spider *orchis*. 56. The Italian mountain *orchis*, with a ferrugineous flower with an oblong tongue. 57. The spotted-leaved Italian *orchis*, with long tongues. 58. The broad leaved handed meadow *orchis*, with long spurs. 59. The broad-leaved palmated meadow *orchis*, with fresh coloured flowers with long spurs. 60. The broad-leaved palmated meadow *orchis*, with snow-white flowers with long spurs. 61. The great narrow-leaved palmated meadow *orchis*. 62. The palmated meadow *orchis*, with spotted leaves. 63. The white-flowered spotted-leaved palmated meadow *orchis*. 64. The spotted leaved palmated meadow *orchis*, with variegated flowers. 65. The greatest

greateſt meadow-palmated *orchis*. 66. The leſſer palmated *orchis*, with long ſpurs to the flowers. 67. The ſmall narrow-leaved ſweet-ſcented palmated *orchis*. 68. The clove-ſcented palmated *orchis*. 69. The white-flowered palmated *orchis*, with the ſmell of elder. 70 The purple-flowered palmated *orchis*, with the ſmell of elder. 71. The palmated frog *orchis*. 72. The caſtrated *orchis*. 73. The broad-leaved marſh palmated *orchis*. 74. The narrower-leaved palmated marſh *orchis*. 75. The common palmated marſh *orchis*, with very narrow leaves. 76. The palmated marſh *orchis*, with ſpotted leaves. 77. The palmated marſh *orchis*, with red leaves and flowers. 78. The green-flowered palmated *orchis*. 79. The largeſt palmated *orchis*, with a bright-red ſweet-ſcented flower. 80. The greateſt palmated mountain *orchis*. 81. The narrower leaved great palmated mountain *orchis*. 82. The white-flowered palmated mountain *orchis*, with ſpotted leaves. 83. The narrower-leaved palmated alpine *orchis*, with a black flower. 84. The narrow-leaved palmated mountain *orchis*, with roſe-coloured flowers. 85. The narrow-leaved palmated mountain *orchis*, with white flowers. *Tourn.* Inſt. p. 443

ORCHIS-*root*, in the materia medica, is otherwiſe named *ſalep*, vulgarly called *ſaloop*. See the article SALEP.

ORCHIS, in ichthyology, a name given by Geſner, and ſome others, to the fiſh, commonly called *orbis*, and by Artedi the ſpherical *oſtracion*, with four teeth, and ſmall ſpines all over it. See the article OSTACION.

ORCHOTOMY, a word uſed by ſome chirugical writers for the operation of caſtration.

ORCYNUS, in zoology, a name by which ſome authors have called the fiſh commonly known by the name of the tunny or thynnus. *Willughby*'s Hiſt. Piſc. p. 176. See THYNNUS.

ORDER, in rhetoric. See DISPOSITION, *Cycl.*

ORDINARY (*Cycl.*)—ORDINARY *Court of Chancery.* See PETTY *bag*.

ORDINATE (*Cycl*)—To find the greateſt and leaſt *ordinates* to curves. See MAXIMUM, *Cycl. & Suppl.*

ORE (*Cycl.*)—Some *ores* are ſo kindly as to melt readily of themſelves, without any aſſiſtance from the common fluxes; theſe are of great value to the owners Other are more intractable and require the aſſiſtance of various fluxes, and others ſo very obſtinate as not be work'd in the larger way, where there can be no very conſiderable expence allow'd for fluxes. On this account many mines remain at this time unwrought, as being untractable in the large way without great charges; hence the improving the buſineſs of fluxes ſerves to render them at once both cheap and effectual, and muſt be of great ſervice to metallurgy.

Some of the cheapeſt and moſt powerful fluxes now in uſe are dry'd wine lees, dry'd cow-dung and horſe-dung, dry'd river-mud, fuller's-earth, iron filings, common ſalt, potaſh, and ſandiver. Theſe may be uſed in the larger works, as nitre, tartar, borax, ſal armoniac, and mercury ſublimate in the leſs: as for compound fluxes they are very numerous, almoſt every operator having his particular noſtrum; and it is plain that ſome fluxes are better adapted to the *ores* of ſome metals than others; but certainly a few general ones might be fixed upon, one or other of which would anſwer all the operator's expectations.

The following three preparations are all very general, very powerful, and not expenſive. 1. Take of nitre, prepared by long boiling in lime water, of ſea-ſalt melted in the fire, of ſandiver, and of dry wine lees, each one part; glaſs of lead three parts, and powdered glaſs eight parts; mix them all well together, and uſe them in an equal weight with ſtubborn *ores*. 2. For a ſtill ſtronger flux take equal parts of white tartar, common ſalt, and nitre prepared as above; calcine all together to a white powder, and mix with it its own weight of glaſs of lead: of this flux add two parts to one part of the moſt ſtubborn ores. 3. For every powerful ſaline flux, take of the ſtrongeſt ſoap-boiler's lees four pounds, of white tartar and common ſalt, melted in the fire, each one pound, boil theſe together, with four gallons of human urine, to a dry ſalt. This flux is particularly ſerviceable where ſulphur and cobalt abound, and render the *ore* very refractory. *Shaw's* Lectures, p. 257.

The *ores* of the richer metals, as gold and ſilver, uſually contain a very conſiderable portion of ſulphur, and Alonſo Barba tells us, that the moſt expert mineraliſts in Peru, always eſteem abundance of ſulphur a ſign of a rich *ore* in the neighbourhood. Among the richeſt *ores* of the mountain of Potoſi, there are ſuch quantities of native brimſtone, that the cavities in the mines are often filled with a blue flame, on only bringing a lighted candle into them ſo as to touch their ſides. It has been wondered at, that where there is abundance of ſulphur in theſe mines, there ſhould be no vitriol found, that being only a metal diſſolved by means of ſulphur; but this objection ceaſes, when we conſider the denſe and compact nature of theſe two metals, which renders them not ſoluble by means of ſulphur, as the others are. Wherever there is ſtore of ſulphur, or of pyrites, or other ſtones which contain ſulphur in the mines of copper and iron, great ſtore of vitriols are always found there alſo, being formed by the corroſion of the *ores* of thoſe metals by ſulphur, which renders them ſoluble in water, from which they again concrete in form of ſalts. Chemiſtry is able to imitate the operations of nature on this occaſion ſeveral ways; for copper, or iron, being formed in thin plates, and either rubbed over with the acid ſpirit of ſulphur, or calcined with powder of common ſulphur, become ſoluble in water, and afford cryſtals of true vitriol wholly analogous to the natural ones, and either blue or green, as iron, or copper are the metals employed; but theſe proceſſes not being able to produce cryſtals of ſalt, or vitriol, from either ſilver, or gold, it is not wonderful that nature is not able to form them by the ſame means.

The general formation of ſulphur from the ores of metals yet lying in the bowels of the earth, is, probably, after this manner. An acid, ſaline, ſulphureous ſteam, or vapour, ſuch as common ſulphur is eaſily reduced to, by heat not greater than that within the bowels of the earth, inſinuating itſelf either through the pores of ſtones, or through their cracks, which are always frequent about the veins of metals, penetrates into the bed of *ore*; ſuppoſe of copper. The vapour is continually ſupplied with freſh quantities from below; and as it blends itſelf with the metal, corrodes it as the fume of brimſtone will the ſame copper in plates. The metal, thus corroded, being ſoluble in water; as we find by experience, it is neceſſary, that the *ore* muſt, under the ſame management, be ſo too; and, in this caſe, the water, which is continually pervading all the ſtrata of the earth, waſhes off the diſſolved metal; and whereever it happens to be ſtayed in ſmall quantities afterward, whether within the vein of the metal, or at a diſtance from it, it cryſtallizes the ſalt it contains, and common blue vitriol is produced, if the metal in the vein be iron. The ſame proceſs is obſerved, and the event is the ſame in all reſpects, when copper is the metal corroded, except that the vitriol, inſtead of blue, is green; this plainly accounts for the obſervation of the workers in copper-mines, that vitriol and brimſtone are uſually found together, the one being a natural conſequence of the other. Sulphur is, indeed, often found where there is no vitriol, but vitriol is very ſeldom found without ſulphur; it being not a diſtinct principle, but a genuine production of ſulphur. Phil. Tranſ. N° 104.

Dreſſing of ORES. See the article DRESSING.

Iron ORE. See IRON.

Gold ORE. See GOLD.

Firm, *Pottern*, and *Steel* ORE. See LEAD *ore*.

OREILLARD, in the manege. See WIDE-*eared*.

OREJUELAS, in botany, a name uſed by ſome authors for the *flos auriculæ*, a flower growing in New Spain, and uſed there in making chocolate. *Dale*, Pharm. p. 339.

OREON, a name given by the antients to a kind of *horſe-tail*, which they found growing on the mountains in wet and damp places. It is to this ſpecies that many authors have attributed the principal virtues of the genus; and this ſeems to have been the ſame with our great water *horſetail*. Neophytus ſays, that it roſe up with a ſingle ſtalk, reſembling a young reed, and that this was compoſed of ſeveral points, which, in the manner of cups, were inſerted one into another; and that from theſe joints the leaves grew, and that they reſembled thoſe of the pine-tree. The branches are what this author calls leaves, and they do pretty well reſemble the leaves of the pine-tree. They are long and ſlender, and of a bright green. Our great *horſetail* loves the heads of ſprings in hilly countries, and is always moſt plentiful in ſuch places.

OREOSELINUM, *mountain-parſley*, in botany, the name of a genus of plants of the umbelliferous kind, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular order on a cup, which afterwards becomes a fruit compoſed of two large, oval, flattiſh, ſtriated, and marginated ſeeds, which ſometimes depoſit their covering. To this it may be added, that the leaves are like thoſe of parſley, or hemlock.

The ſpecies of *oreoſelinum* enumerated by Mr. Tournefort are theſe: 1. The great, parſley-leaved *oreoſelinum*. 2. The leſſer, parſley-leaved *oreoſelinum*. 3. The hemlock-leaved marſh *oreoſelinum*. 4. The ſhrubby, aniſe-leaved, African *oreoſelinum*, which produces the *galbanum* of the ſhops. This is called by many *ferula galbanifera*. *Tourn.* Inſt. p. 319.

OREXIS, *appetite*. The appetite, when exceſſive, or otherwiſe vitiated, is diſtinguiſhed by medical writers into ſeveral kinds, and deſcribed under ſeveral names, according to its difference in degree, and other particulars.

The firſt kind is the *addephagia*: this is the name given that ſpecies in which the food is not only eaten in too large a quantity, but is ſwallowed in a particularly ravenous manner.

The ſecond is the *orexis canina*: in this caſe the patient is continually eagerly longing for food, and if it is not ready ſo ſoon as he deſires, he is ſubject to fainting fits after the recovery, from which he does not feel the ſame craving appetite.

The third is the *pica*, or *ſitta*: this is the caſe when the patient has an eager appetite to things not fit for food, ſuch as chalk, cinders, tobacco-pipes, and the like.

The fourth is the *malacia*: this is diſtinctively made the name of that ſpecies of *exceſſive appetite* in which the patient

ent has a great desire for some particular things, but those of the nature of common food, and usually of the nicer, and more delicate kind.

Signs attending it. An over-large eating is usually attended with cardialgias, anxieties, and straitness of the breast; after this, with nauseas, eructations, and not unfrequently with a vomiting, or a diarrhœa; often a dizziness of the head follows, and sometimes very violent pains in it, with a lassitude and pains in the limbs, and pains and rumblings in the abdomen; finally, sometimes fevers, sometimes suffocations, and sometimes convulsions, are the consequence.

Persons subject to it. The *excess of appetite*, in its different kind, affects different sets of people. The *addephagia* is usually the case with boys who are just come to distinguish good taste, and feed as their parents do; and sometimes with women who have more sensation than judgment. People in general of sanguine and sanguineo-phlegmatic habits, eat more food than others; and choleric persons often eat, and usually swallow their food, quicker than others. Persons of melancholic habits, are usually of all others, the least eaters. Finally, people, in general, eat heartily, and even excessively, when they come, from a coarse and homely diet, to a more elegant and agreeable one; and this *excessive appetite* becomes a symptomatic complaint with people who are troubled with worms, and with hypochondriac complaints, with quartans, and often with epilepsies.

The *malacia* seems particularly to affect women during the time of their being with child. The *pica* is common to women with child; to young women before the first eruption of the menses; with those who are emaciated by a too violent flux of that discharge; and, finally, sometimes, though more rarely, to persons in epilepsies, and in quartans.

Causes of it. *Excessive appetite* is generally occasioned by a too great love to agreeable tastes, which generally degenerates into a custom of devouring things of agreeable flavours greedily; and, finally, into an habitual and almost necessary desire of them. In infants who are over-much fed by their nurses, the fault is not in the will, but even this also, in fine, becomes habitual, and not to be overcome easily.

Prognostics in it. *Excessive appetite* does great mischief among men, and is a very common complaint, inasmuch that there are ten thousand who err in eating more than nature requires, for one who eats less. It is common for persons recovered from illnesses to have an *excessive appetite*; but, if this be indulged to the extent, it usually brings on either a return of the same disease, or, at least, one equally bad. People, after long hunger, have also the same sort of *excessive appetite* as after diseases, but there have been frequent instances, that those who indulged it freely have died upon the spot. In general, the consequences of *excessive appetite* indulged, is diseases of many kinds, particularly obstructions of the viscera, cachexies, and atrophies. When the *pica* attends a quartan, it very often happens, that all medicines are vain in the attempt of a cure, till that unnatural *appetite* has been perfectly sated. When young girls fall into a *pica* from a want of the menses at a due time, they are always relieved from it by the appearance of that evacuation; but in persons who fall into it from inordinate profluvia of that discharge, it is usually very difficult of cure, and the same difficulty always attends it when hereditary.

When people have eat to an immoderate degree by reason of any of these kinds of *excessive appetite*, the best method of relieving them, is by giving them large draughts of warm water, till they vomit; or, if the stomach will not be brought to discharge its contents by this means, a few grains of emetic tartar are to be given, or a small dose of ipecacuanha. After this the bowels are to be gently relaxed; but this is by no means to be done by any violent medicines, the stimulus of which would bring on violent and dangerous pains. After the mischief of a monstrous repletion is, by this means, got over, the best preservative for the future is abstinence, and gentle exercise. There have, however, been instances of people being cured of this disease, by palling the *appetite* by large draughts of oil, regularly taken, three times a day. The good women have a way of curing the *pica* in girls, by making the chalk, and other such things which they are to eat, bitter, or of some other disagreeable taste; when a girl has been once tricked in this manner, she will often have as violent a distaste to these unnatural eatables, as she before had an inclination for them; and, in like manner, grown persons who have violent *appetites* to certain particular foods, have been cured by conveying into them an infusion of tobacco, or some other such thing as will provoke vomiting, so disguised as not to be tasted, while eaten. When the stomach and bowels, over-loaded by these meals, are, of themselves, discharging their abundant contents, by vomit, or stool, it is a very rash and dangerous practice to give any thing to stop those emotions till the whole is thoroughly carried off. *Junker's* Consp. Med. p. 605, seq. See the articles Canine, Bulimy, &c.

ORFUS, in zoology, the name of a fresh water fish, common in Germany, and called there the *orst*, the *oerve*, and the *nersling*; seeming by the descriptions of Gesner, and other authors, to be the same with our *rudd*, or *rubellio fluviatilis*. See Tab. of Fishes, N°. 43. *Willughbgy's* Hist. Pisc. p. 252.

ORGANO, in the Italian music, is used to signify the thorough bass. It is usually scored with figures over the notes, for the harpsichord, bass-viol, and lute.

ORGUES, (*Cycl.*) are preferable to herses, or porteullises, because these may be either broke by a petard, or they may be stopped in their falling down; but a petard is useless against an *orgue*; for if it break one or two of the pieces, they immediately fall down again, and fill up the vacancy; or if they stop one or two of the pieces from falling, it is no hindrance to the rest; for being all separate, they have no dependance upon one another.

ORICHALCUM, or Aurichalcum, *brass*. See the article Brass, *Cycl* and *Suppl.*

It is to be observed, that zink is the metal which has the power of giving a yellow colour to copper. We long supposed, from calamine's answering the same purpose, that two different substances could do this; but it has been since found that they are the same, and that calamine is no other than the ore of zink. See the article Calamine.

It is evident from all accounts, that the *orichalcum* of the antients was a fictitious substance, not a natural metal. They made it on the same basis that we make brass at present; but they had several ways of doing it, and distinguished it into several kinds. They had a white sort in frequent use and great esteem; and even the yellow they distinguished into two principal sorts, under different names. The *orichalcum* and *æs flavum*, brass and yellow copper, are with us synonymous terms; but with them they were used to express different combinations of the ingredients. Pliny tells us indeed of a natural mine of this metal found somewhere, and that the metal produced from it was in very great esteem. He says, that the making of brass was first found out in Cyprus, and that it was an artificial metal, but that this natural kind was greatly superior to it, and was the only kind in esteem, so long as the mine yielded any of it, but that at last it was exhausted. This account is unquestionably erroneous; but yet it has taken so much footing in the world from the authority of this author, that many suppose it truth, and think that we have not at present the metal called *orichalum* by the antients. They who suppose, according to Pliny, that there was once a vein or mine of this metal, which was afterwards lost again, certainly err, and there is sufficient proof of the truth of the contrary opinion by all the Greek writers, declaring the manner in which *oricalum* was made, which was with copper and calaminaris-stone, as brass is made at this time. Some indeed have somewhat perplexed the matter, by adding the word pseudoargyron, as a part of the composition. Among these is Strabo, but by that author in other places we find, that all that he means by this name is, the calamine found in silver mines, which resembled, as the common calamine does, some kinds of silver ore; so that the two accounts come to the same thing.

Orichalcum, or Aurichalcum *album*, *white brass*. This was a metal well known among the antients, and celebrated by Aristotle and by Strabo, and others, under the name of κραμα λευκον. It was made by mixing an earth with copper while in fusion; but what that earth was, we are not informed.

There have been many objections made to the name *aurichalcum album*, as a contradiction in terms. The epithet white being by no means allowable with a word which is generally supposed to express gold-coloured brass; but this is an error. The truth is, that *aurichalcum* is an error in orthography; the true word being *orichalchum*, Ορειχαλκον, mountain copper. The Romans changing the *o*, in a Greek word into *au*, when they adopted it into their own language, is common; and we daily see so many instances of it, that this custom alone might justify it, were the word always written *aurichalchum* by the Romans; which, however, it is not, Virgil, and several others expresly calling it *orichalchum*, according to the original or proper orthography: there was, therefore, no idea of gold, nor any other denomination of colour intended in the word *aurichalchum*; all that was expressed by it was, mountain copper; and this term was made to express a mixed metal, made of copper and of some earth, stone, or other mineral. In this sense, the mixture of copper with that of earth, whatever it was that turned it white, was as properly called *orichalchum album*, as that with calamine was *orichalchum flavum*, or simply *orichalchum*. We know several ways of turning copper white, one of which was much practised some years ago, and spoons and other utensils made of it, had the name of *alchymy* things; but this was done by means of arsenic; a thing not known to the antients: this, therefore, could not be the same with their white brass, and indeed, none of our methods seem to be the same with theirs, since the metal is debased by all ours, and becomes brittle; whereas, in their management, according to their own accounts, it seems not to have lost any thing of its ductility, tho' it acquired a peculiar brightness.

ORIENTAL, (*Cycl.*) in astronomy. A planet is said to be *oriental* when it rises in the morning before the sun.

Hybernal ORIENT, that point of the horizon where the sun rises when in the first degree of Capricorn. See OCCIDENT.

ORIGANUM, *wild marjoram*, in botany, the name of a genus of plants, the characters of which are these: the flower consists of one leaf, and is of the labiated kind, the upper lip is erect, of a roundish shape, and bifid, the lower is divided into three segments. The pistil arises from the cup, and is fixed in the manner of a nail into the hinder part of the flower, and surrounded with four embryos, which afterwards become many seeds, and ripen in the cup of the flower. To these marks, it is to be added, that the *origanums* all bear their flowers in a sort of scaly ears or spikes.

The species of *origanum* enumerated by Mr. Tournefort are these: 1. The common *origanum*. 2. The common *origanum* with variegated leaves. 3. The white wild *origanum*. 4. The low, woolly, procumbent *origanum*. 5. The heracleotic *origanum*, or *cunila gallinacea* of Pliny. 6. The *origanum* of Crete, called *pot-marjorum*, the genuine hyssop of the antients, according to Lobel. 7. The round-leaved *origanum*. 8. The *origanum* with the smell of pennyroyal. 9. The broad-leaved, smooth, low *origanum*. 10. The Canada *origanum*, with umbellated flowers. 11. The broad-leaved woolly cretic *origanum*, usually known by the name of *dittany of Crete*. 12. The *origanum* of mount Sipylus. 13. The slender-headed Canada *origanum*. 14. The woody *origanum* of Syracuse, with large umbels of flowers. *Tourn.* Inst. p. 199.

Origanum is a very pleasant aromatic. An infusion of the plant, drank in the manner of tea, is of great service in disorders of the stomach; it absterges the viscous matter apt to lodge there, and thereby promotes an appetite and assists digestion. It also dispels flatus's, and is esteemed good in jaundices, and all other chronic cases occasioned by obstructions of the viscera.

ORIGINARY, *originarii*, among the Romans, an appellation given to slaves born in their master's houses, who were otherwise called *vernæ*. *Hofm.* Lex. in voc.

ORIOLUS, in zoology, a name by which several authors have called the *galbula*, a very beautiful yellow bird of the thrush kind, remarkable for its manner of hanging its nest. *Albertus.* See the article GALBULA.

ORITES, in natural history, the name of a stone described by the antients, and celebrated by the writers of the middle ages for its wonderful virtues. Pliny says, that it was round, and remained unhurt in the fire, and that some called it *Sideritis*. To this the later writers have added, that there are three kinds of it; the first round and black: this rubb'd over with oil of roses was famous for the bites of venomous beasts. The second was green, variegated with veins and spots of white: this was to be carried about people, to preserve them from many sorts of injuries. And the third was composed of parallel plates, and said to have the virtue of causing abortion, if only carried in the pocket.

ORITORIUS *lapis*, a name given by Ludovicus Dulcis, and some other authors, to the *ochreoferreous ætitæ*, or eagle stones; particularly to a species of them common in Germany, and used in the shops there, and in some other places, under the name of *eagle stones*. These are of a brownish colour and smooth surface, and are easily broken, being only composed of a thin crust of ferrugineous earth, enclosing several small lumps of a greenish marle, which rattle in it when shaken.

ORIZEUS *color*, a term used by authors to express the yellow colour in the eyes and urine of persons afflicted with a jaundice. See JAUNDICE.

ORKNEY-*beans*, in natural history, a name given by authors to a sort of fruit found on the shores of the *orkney* islands near Scotland. These are of several distinct species, and are none of them the produce of those islands, nor of any places thereabout, but are probably of American origin, many of them being plainly natives of Jamaica.

They are found principally on those coasts which are most exposed to the waves of the great ocean, and are on these so plentiful, that they might be gathered in large quantities, if of any value; but the only use they are put to is the making snuff-boxes out of them. Sir Robert Sibbald, and Mr. Wallace, in their accounts of Scotland, have both named them under the title of *Molucca beans*. See MOLUCCA *beans*.

ORLEANA, in the materia medica, the name of the *arnotto*, or *uruca*. *Dale*, Pharm p 388.

ORMENA, among the antient naturalists. See ASPARAGUS.

ORNICUS *lapis*, a name given by some authors to the *sapphire* of the antients, which is a peculiar species of our *lapis lazuli*, in which the gold-coloured matter is not dispersed in veins, but in separate spots of the form of a star. It was first called *o inificus*, and *orinus*, by corruption from *aurinus*, golden, and thence came, at length, the word *ornicus*.

ORNITHIÆ, a name given by the antients to certain winds, which usually blew in spring, at the time when the birds of passage came over to them Pliny says, that these winds lew from the West, and that, by some, the Etesian w inds ere called by this name. Others suppose that they b lew from the North, or North-West.

ORNITHOGALUM, *star of Bethlehem*, in botany, the name of a genus of plants, the characters of which are these: the flower is liliaceous, being composed of six petals, arranged in a circular form. The pistil stands in the center of the flower, and finally becomes a roundish fruit, or seed-vessel, divided into three cells, and containing a number of oblong seeds; to this it is to be added that it has a bulbous or tuberous root, in which it differs from the phalangium, which has a fibrous one.

The species of *ornithogalum* enumerated by Mr. Tournefort are these: 1. The great Syrian *ornithogalum*, with umbellated flowers. 2. The great, narrow-leaved, *ornithogalum*, with umbellated flowers. 3. The broad-leaved, middle-sized, white *ornithogalum*, with umbellated flowers. 4. The narrow-leaved, middle-sized, white *ornithogalum*, with umbellated flowers. 5. The lesser white *ornithogalum*. 6. The umbellated *ornithogalum*, with bluish white flowers. 7. The greatest, broad-leaved, Alexandrine *ornithogalum*. 8. The Indian, broad leaved, *ornithogalum*. 9 The great, narrow-leaved, *ornithogalum*, with greenish white flowers. 10 The great, narrow-leaved, *ornithogalum*, with flowers in spikes. 11. The spiked *ornithogalum*, with snow-white flowers. 12. The great, white-spiked, French *ornithogalum*. 13. The great, white-spiked, Byzantine *ornithogalum*. 14. The spiked *ornithogalum*, with greenish-white flowers. 15. The Spanish white-flowered, spiked *ornithogalum*. 16. The pale, blue-flowered *ornithogalum*. 17. The *ornithogalum* with a large flower growing on a smaller. 18. The great, pale yellow *ornithogalum*. 19. The yellow *ornithogalum*, with larger flowers. 20. The tuberous-rooted, African, yellow *ornithogalum*, with onion-like leaves, and sweet-scented flowers. 21. The common, wild *ornithogalum*. 22. The lesser, wild, yellow *ornithogalum*. 23. The narrow-leaved, bulbiferous, *ornithogalum*. 24. The yellow-flowered, Portugal *ornithogalum*, with capillaceous leaves. 25. The Indian *ornithogalum*, with yellowish-green flowers. 26. The African *ornithogalum*, with green flowers, growing one out of another. 27. The one-leaved, spiked *ornithogalum*, with a snow-white, sweet-scented flower. 28. The blue-flowered, two leaved, German *ornithogalum*. 29. The trifoliate, German *ornithogalum*, with deep blue flowers. 30. The bifoliate, German *ornithogalum*, with flesh-coloured flowers. 31. The bifoliate, German *ornithogalum*, with white flowers. 32. The narrow-leaved, white, late-flowering, *ornithogalum*. 33. The blue-flowering *ornithogalum*, with yellowish green stamina. 34. The purple-flowered *ornithogalum*. 35. The spiked *ornithogalum*, with grey flowers. 36. The blue-flowered, Constantinople *ornithogalum*. 37. The Constantinople *ornithogalum*, with bluish purple flowers. 38. The Constantinople *ornithogalum*, with a white flower. 39. The Constantinople *ornithogalum*, with dusky, bluish flowers. 40. The borrage-flowered, Constantinople *ornithogalum*. 41. The blue *ornithogalum*, with striated flowers. 42. The Spanish, deep-blue, *ornithogalum*. 43. The great, purplish, blue *ornithogalum*. 44. The summer *ornithogalum*, with flowers standing alternately on the stalks. 45. The great, autumnal *ornithogalum*, with pale, purple flowers. 46. The great, autumnal *ornithogalum*, with white flowers. 47. The lesser, autumnal *ornithogalum*, with purple flowers. 48. The lesser, autumnal *ornithogalum*, with blue flowers. 49. The little, spring *ornithogalum*. 50. The blue-flowered, Portugal *ornithogalum*. 51. The broad leaved, Portugal *ornithogalum*, with violet-coloured flowers. 52. The broad-leaved, Portugal *ornithogalum*, with flesh-coloured flowers 53. The broad-leaved, Portugal *ornithogalum*, with greyish flowers. 54. The broad-leaved, Portugal *ornithogalum*, with white flowers. 55. The Peruvian, eriopherous *ornithogalum*. 56. The oriental, eriopherous *ornithogalum* 57. The *ornithogalum* of the sea shores, commonly called the *red-rooted squill*. 58. The white-rooted, maritime *ornithogalum*, commonly called the *white-rooted squill*. 59. The maritime *ornithogalum*, with an esculent root, called the *esculent squill*. *Tourn.* Inst. p. 378.

The several species of this plant produced in our gardens are all propagated with great ease by the off-sets which the roots produce in very great abundance. The best time to transplant the roots is in the beginning of July, when the leaves are decayed. They should have a light, sandy soil, which, if it be over-dunged, will decay, and rot the roots: they continue flowering a long time, and are a very great ornament in gardens, but they ought to be transplanted once in two or three years, otherwise the roots grow luxuriant in off-sets, and the flowers are weak. *Miller's* Gard. Dict.

ORNITHOPODIUM, in botany, the name of a genus of plants, the characters of which are these: the flower is of the papilionaceous kind, and its pistil which arises from the cup finally becomes a hooked, or falcated, jointed pod, of a flattish and undulated form, and containing, in each joint, one roundish seed. To this it is to be added, that the pods of this plant usually grow four or five together; and by that means in their shape resemble a bird's foot.

The species of *ornithopodium* enumerated by Mr. Tournefort are these: 1. The great *ornithopodium*. 2. The little *ornithopodium*. 3. The *ornithopodium* with roots composed of knotty tubercles. 4. The scorpioides *ornithopodium*, with flatted pods.

pods. 5. The Portugal, scorpioide *ornithopodium*, with undulated pods. 6. The purslain-leaved *ornithopodium*. *Tourn.* Inst. p. 400.

ORNITHOSCOPI, ὀρνιθοσκόποι, in antiquity, diviners, or soothsayers, who made predictions, and drew omens, from birds. They were likewise called *ornithomantes*, and *orneoscopi*, &c. *Potter*, Archæol. Græc. l. 2. c. 15. T. 1. p. 321.

OROBANCHE, *broom rape*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the personated kind, divided into two lips, the upper of which is galeated, and the lower divided into three segments. The pistil arises from the lower part of the cup, and finally becomes an oblong fruit, consisting of only one cavity, which usually contains extremely minute seeds.

The species of *orobanche*, enumerated by Mr. Tournefort, are these: 1. The great large flower'd *orobanche*, smelling like cloves. 2. The great stinking *orobanche*. 3. The great Portugal *orobanche*, with purplish flowers. 4. The small flowered *orobanche*. 5. The bluish flowered *orobanche*. 6. The branched, purple-flowered *orobanche* 7 The blue-flowered, branched *orobanche*. 8. The whitish-flowered, branched *orobanche*. *Tourn.* Inst. p. 175.

OROBO, a name given by the chemists to any sort of metallic glass.

OROBOIDES, a name given by Hippocrates, and other authors, to a furfuraceous sediment in the urine of persons who have the jaundice: it is usually of a redish brown colour; and is not peculiar to that disease, but is found in some others.

OROBUS, *bitter vetch*, in botany, the name of a genus of plants, the characters of which are these: the flower is of the papilionaceous kind; from the cup there arises a pistil, which is covered with a membrane, and finally becomes a membranaceous pod of a cylindric figure, usually containing oval seeds. To this it is to be added, that the leaves grow in pairs on a middle rib, which terminates in a point.

The species of *orobus*, enumerated by Mr. Tournefort, are these: 1. The purple-flowered, spring *orobus* of the woods. 2. The vernal, wood *orobus*, with a pale red flower. 3. The broad-leaved *orobus*, with small purple flowers. 4. The broad-leaved *orobus*, with small pure white flowers. 5. The narrow-leaved, asphodell-rooted, wild *orobus*. 6. The vetch-leaved, wood *orobus*. 7. The red-stalked, vetch-leaved, wood *orobus*. 8. The Italian, narrow-leaved *orobus*, with variegated flowers. 9. The wood *orobus*, with oblong smooth leaves. 10. The English, wild, wood *orobus*. 11. The Pyrenæan *orobus*, with nervous leaves. 12. The American *orobus*, with scarlet fruit, marked with a black spot, by some called the *phaseolus* of America, and the *abrus*, and scarlet Indian pea *Tourn.* Inst. p. 393.

OROCONITES, in the materia medica, a name given by Hippocrates, and others, to a bulbous root that is recommended as a rich food. It has the name from the Greek, ὄρος, a mountain, and κωνιτις, of a conic figure. This shews that it was a root of such a shape, found growing in mountainous places; but the learned have been puzzled in their attempts to find out what it was.

Guillandinus is of opinion, that the *oroconites* of Hippocrates is the *trasi*, or sweet *cyperus* root, but there are many arguments against this opinion, though the two circumstances expressed in its name, that is, the place of growth, and the shape of it, are sufficient to throw this to the ground. The *trasi* grows in low marshy grounds, near waters, and its roots are small tubera of the shape of a hazel-nut, whence the Spaniards, who are very fond of them, have called them *avellanda*. The Arabians have a root which they call the bulb, by way of eminence. This seems, indeed, to be the same with the *oroconites* of Dioscorides; and they give the same account of its virtues, and tell us, that it grew far from waters on the mountains of Syria, near Damascus, and elsewhere, and that it was of the size and shape of a pear; this may very well be called a conic shape in a root.

ORONTIUM, in botany, a name given by some authors to the *antirrhinum*, called in English *calf's snout*, or *snap-dragon*. *Ger.* Emac. Ind. 2.

OROSPIZA, in zoology, a name by which the antient naturalists called the *brambling*, or *mountain finch*.

The word is Greek, and expresses *mountain-chaffinch*. See the article MONTIFRINGILLA.

ORPELLO, a preparation of brass used in the glass trade, and prepared in this manner: cut plates of brass into small pieces, and place them in a luted crucible, in a strong fire, but not so violent as to melt it. Let it stand in this manner for four days, in which time it will be well calcined; when cold, powder, and sift it, and finally grind it on a porphyry. This will be a black powder; spread this on tiles, which place on burning coals in the leer, near the hole, for four days; take off the ashes that may fall into it, and finally powder and sift it fine for use It is known to be nicely prepared, when, on mixing with the melted metal in the glass furnace, it makes it swell and boil.

The colour it gives is a very elegant sky-colour, and a sea-green, or a mixt colour, between them, according to the quantity, and degree of calcination. *Neri's* Art of Glass, p. 35.

ORPHAN (*Cycl.*) — Among the Athenians, the *orphans* whose fathers had lost their lives in the service of their country, were under the guardianship of the *polemarchus*, who was to provide them with a competent maintenance, out of the public treasury. See POLEMARCHUS.

ORPHANUS, in natural history, a name given by some authors to a poor species of *opal*, called by some *pseudo-opalus*: it has no other colours beside a milky white, and purplish red. This stone is frequent in Germany, and Hungary.

ORPHEOTELISTÆ, ὀρφεοτελεσταί, in antiquity, persons initiated in the Orphic mysteries. They assured all that were admitted into their society of certain felicity after death; which when Philip, one of that order, boasted of, Leotychidas, the Spartan, replied, Why do not you die then, you fool, and put an end to your misfortunes, together with your life? At their initiation, little else was required of them besides an oath of secresy. *Potter*, Archæol. Græc. T. 1. p. 497.

ORPHEUS, in zoology, the name of a fish caught in the Archipelago. It is of a broad and flat figure, and of a fine purple colour; its eyes are large and prominent, and its teeth serrated; it has only one fin on the back, and the anterior rays of that are prickly, the others soft to the touch. Its anus is small, and it is said to have no passage for the semen.

This was the fish called *orpheus* by the antients, but the modern Greeks call another fish by that name. This is of a flat figure, but very thick, has a small mouth, and is covered with small, but very rough scales, which adhere very firmly to the flesh; the tail is not forked; it has fleshy lips, and very small teeth; its back and sides are black; its belly white; it has a large black spot at the root of the tail Its head is reddish, and its fins are very elegantly diversifyed with various colours; it has only one back fin, and that has the anterior ray prickly, the hinder ones not at all so. It grows sometimes to twenty pound weight, and is much esteemed among the modern Greeks. *Gesner* de Pisc. p. 752.

ORPIMENT, (*Cycl.*) *auripigmentum* — *Orpiments* are inflammable fossile substances compofed of numbers of thin flakes, like the talcs, which easily split, and are separated from one another, and are flexile, and not elastic, soluble in oil, fusible in a moderate fire, and yielding in burning an offensive smell like that of garlic.

These, like the talcs, are, in some of the species, composed of large plates, or flakes, each making the whole surface of the mass, and, in others of small flakes lodged in extraneous matter, or cohering alone into a mass in form of spangles.

Of this genus of fossils, there are only three known species: 1. A broad-flaked, gold-coloured kind, well known among the antients, as is plain from the description of it left us by Dioscorides, and much esteemed at present by our painters. This is found in several places, as in the islands of the Archipelago, in the mines of Goffelaer, in Saxony, in some parts of Turky, and the East-Indies, and in its utmost purity about Smyrna; this makes the finest of all yellows in painting. 2. The small-flaked, yellow kind, which is the common *orpiment* of the shops, and is a fine colour, though greatly inferior to the former. This is found in many parts of the Turkish dominions, and in Germany. And, 3. Red *orpiment*. This has been a name given by the more judicious to sandarach, and, by the vulgar, to red arsenic, but is to be restrained only to this fossile, which is of a fine bright red, and of the regular texture of the *orpiments*, and answering all their characters. This is a very beautiful substance of a fine bright red, very glossy, and a little transparent, and is found in the Turkish dominions, in the islands of the Archipelago, and even in our own country, Dr. Hill having lately received some of it from Cornwall, under the name of red mundic.

The English druggists are guilty of an unpardonable piece of ignorance, in that, in general, they know no difference between yellow *orpiment*, and the yellow factitious arsenic, which they regularly sell under its name; the *orpiment* is known to be a safe internal medicine, and the thing they sell under its name is a very terrible poison. The colour-men, however, who sell both are well acquainted with the difference. *Hill's* Hist. of Foss. p. 204.

ORRHAGOGA, a name given by the antients to such medicines as operated violently, as purges, and evacuated serous and watery humours.

ORRHOPIGION, a word used by anatomical authors, sometimes to express the extremity of the spine, but more frequently the line or seam which runs from the penis along the middle of the scrotum to the anus.

ORRHOPISSA, a name given by the antients to the thinner or more fluid parts of tar.

ORRICE, a name given by the vulgar to the *iris-root*. See the article IRIS.

ORRUS, in botany, a name by which many of the antients called the cultivated pine tree, from its being remarkably full of juice.

The first person who has given us the name is Theophrastus; but he is followed in it not only by the other Greeks, but also by the Latins, who have called the same tree for the same reason *sapinus*, a contraction or abbreviation of the word *sapapinus*, the juicy pine. Pliny tells us, that this last was the name of the manured pitch tree; but in this he errs, for Vitruvius, and others, tell us that the pine nuts, *nuces pineæ*, which were eaten and

and ufed in medicine, were the fruit of the *fapapinus*, or *fapinus*; and it is evident, that thefe muft be the produce of a pine tree, not of a pitch tree, or any thing of the fir kind.

ORTHOCERATITES, in natural hiftory, a name by which fome late authors have called a fpecies of fea fhell, found frequently foffile, but not known at prefent in its recent ftate; called by others *polythalamium* and *tubulus marinus concameratus*. It is ufually ftrait, but fometimes its end is twifted like the *cornu ammonis*. See TUBULIS *Concamerati*.

ORTHODOXI, in botany, fuch fyftematic writers as have formed their methods on the true natural foundation, and divided the plants under their confideration into claffes and genera, according to the characters of their parts of fructification. Thefe are either the *univerfales*, or *particulares*; by the firft are meant, thofe who have thus ranged the whole vegetable world; and by the latter, thofe who have undertaken only fome one clafs of plants, as the umbelliferous, &c. *Linnæi*, Fund. Bot p. 2.

ORTHODROMICS, that part of navigation which teaches the art of failing in the arch of fome great circle.

The word is Greek, ορθοδρομικα, derived from ορθος, *rectus*, ftreight, and δρομος, curfus, run or diftance; *q. d.* the ftreight or fhorteft diftance; and this can only be in the arch of a great circle.

ORTHRAGORISCUS, in zoology, the name ufed by Rondeletius, and fome other authors, for the fifh more commonly known by the name of the *mola*, and called in Englifh the *fun fifh*. *Willughby's* Hift.Pifc. p. 151. See the article MOLA.

ORTYGOMETRA, in zoology, the name of a bird called in Englifh the *daker-hen*. It is fomewhat larger than the quail. Its body, in fhape, refembles the common hen. It has two dusky lines on the head: its breaft and belly are white: its throat of a dusky brown: its back feathers are black in the middle, and of a tawny colour at their edges: its thighs are variegated with tranfverfe-white ftreaks. It is common in Ireland, and in fome of the northern counties of England, particularly in Northumberland. The noife it makes is only *crex, crex*, whence the antients have called it by that name. The Italians call it *re edelle quaglie*, or the *king of the quails*. It is a very delicately tafted bird. *Ray's* Ornithol. p. 122.

ORVALA, in botany, the name given by Linnæus to a genus of plants, called *papia* by Micheli. The characters are thefe: The perianthium is compofed of one leaf, it is tubulated and dilated at the mouth, and is crooked and divided into five fegments; the lower two being fhorter than the reft. The flower is compofed of one petal, and is not of the labiated kind; the tube is of the length of the cup. The limb is erect, long, and divided into four fegments. The upper of which is oblong, convex, and falcated, and lunated at the point. The lower is oblong, and is alfo lunated at the point, and the fide ones are oblong and pointed, and divided each into three fegments. The ftamina are four filaments of the length of the flower; they are placed under the upper fegments of the flower; the antheræ are two in number. The germen of the piftil is divided into four; the ftyle is fimple, and of the fame length with the ftamina; the ftigma is bifid, and acute. The feeds are four, and of an oval kidney-like fhape. *Linnæi*, Gen. Plant. p. 278.

ORVALA, in botany, is alfo a name ufed by fome authors for the *horminum*, or *clary*. *Ger.* Emac. Ind. 2.

ORYCTOGRAPHY, is that part of natural hiftory wherein foffils are defcribed. *Wolfm.* Difc. Prælim. Logic. §. 81.

ORYCTOLOGY, is that part of phyfics which treats of foffils, or it is the fcience of foffils. Under this head comes the doctrine of falts, fulphurs, ftones, gems and metals. *Wolfm.* Difc. Prælim. Logic. §. 81.

ORYGMA, ὄρυγμα, among the Athenians, a name given to the pit, more ufually called *barathron*; (See BARATHRON) whence the public executioner received the appellation of ὁ ἐπὶ τῷ ὀρύγματι. It was a dark noifome hole, and had fharp fpikes at the top, that no man might efcape out; and others at the bottom, to pierce and torment fuch as were caft in. From its depth and capacioufnefs, it came to be ufed proverbially for a covetous mifer, or voracious glutton, that is always craving, and can never be fatisfied; and fuch a one the Latins called *barathro*. *Potter*, Archæol. Græc. l. 1. c. 25. T. 1. p. 134, feq.

ORYX, in zoology, an animal mentioned by Ariftotle and Pliny, with only one horn. Pliny makes it a fpecies of wild goat; but Columella thinks it was a kind of deer. It is faid, that this creature was of great ufe in Africa, to relieve the fcorched inhabitants from thirft, there being always found in its body vefieles full of a very wholefome and pleafant liquor. *Hofm.* Lex, in voc.

ORYZEUM, a name given by many of the chemical writers to gold.

OS (*Cycl.*) — Os *argenteum*, in natural hiftory, the name of a fpecies of fhell fifh, of the round mouthed fnail, or *lunaris cochlea* kind. It has a very elegant filver colour in the round opening, or mouth of the fhell. See LUNARIS *Cochlea*.

Os *aureum*, the golden mouth, in natural hiftory, a name given to a fpecies of cochleæ of the lunar kind, or of that genus which have a round mouth. This, in the *os aureum*, is of a fine yellow. See LUNARIS *Cochlea*.

Os *calcis* (*Cycl.*) — This is the largeft bone of the foot, of which it makes the pofterior part, and in fome meafure the bafis. It is oblong and very irregular, and may be divided into a body and two apophyfes, one great and anterior, the other fmaller, lateral and internal. The body of the *os calcis* has fix fides; one pofterior, one anterior, one fuperior, one inferior, and two lateral. The pofterior fide is broad, unequally convex, and as it were divided into two portions, one fuperior, fmall and polifhed, the other inferior, much larger, unequal, and rough, which, in children, is an apophyfis, and may be termed the *tuberofity* of the *os calcis*. The lower part of it is bent downward, and terminates in two tubercles or obtufe points, which belong rather to the inferior than the pofterior fides of the bone. The upper fide may be divided into two parts, one pofterior and unequal, having a fmall depreffion; the other anterior, convex, and cartilaginous, proportioned to the great inferior cavity of the aftragalus. This fide is turned obliquely forward, and by this obliquity becomes part of the forefide, the remaining part of which is loft in the anterior apophyfis. The lower fide is narrow, and behind it lies the two tubercles already mentioned, of which the internal is the biggeft; they both ferve for the infertion of the aponeurofis in the fole of the foot, but chiefly the biggeft. The two lateral fides are continued over the anterior apophyfis, the external is gently convex and unequal, covered only with the common integuments and ligaments; the internal is hollow and depreffed. The greater anterior apophyfis lies in the fame direction with the body, being a continuation thereof. It has five fides or remarkable parts, and were it not for the body would have a fixth. The upper fide has an irregular and unequal depreffion, which, together with that in the apophyfis of the aftragalus, forms a confiderable foffula. And its anterior extremity has a fmall cartilaginous furface, anfwering to one of thofe in the apophyfis of the aftragalus. The anterior fide of the apophyfis is broad, oblique, cartilaginous, partly convex and partly concave, and is articulated with a like furface of the os cuboides: this is the forefide of the whole *os calcis*, when confidered without any divifion. The outfide of the apophyfis is very rough, being a continuation of the outfide of the body, with a tubercle or eminence of the place where the two fides meet. This, however, is not found in all fubjects. On the lower part of this tubercle is a cartilaginous furface for the paffage of the tendon of the *peronæus longus*: fometimes we fee only fome fmall veftiges of this eminence, and often none. We fometimes alfo meet with a cartilaginous furface, fmall, lower down, and more forward, near the anterior extremity of the apophyfis, for the paffage of the fame tendon. The lower fide is a tuberofity continued from the fide of the body, and defigned for the infertion of mufcles. The lateral apophyfis is almoft common to the body, and to the great anterior apophyfis, and increafes the cavity on the infide of the *os calcis*. On its upper part it has a very fmooth cartilaginous furface, articulated with one of the inferior furfaces of the aftragalus. This apophyfis is very low down, and its inferior part is fmooth for the paffage of tendons. *Winflow's* Anatomy, p. 97, feq.

Os *calcis luxated*. It fometimes happens, that the *os calcis* above, and no other bone of the foot, is difplaced or luxated by fome external force; and this happens fometimes toward the external, fometimes toward the internal fide of the foot. When this accident happens, it is eafily difcovered by the violent pain it occafions; and by the inequality of the part; that is, there is a cavity plainly obfervable in one part, and a tumor in the other, on the place. The reduction of this diflocation is very eafy. The patient is to be placed on a bed, and while two affiftants extend the limb in the oppofite directions, the furgeon replaces the diflocated bone with his fingers, and the preffure of the palm of his hand, and then there is no more than a proper bandage and reft required to the cure. *Heifter*, Surg. p. 174.

Os *cuneiforme*. This in the carpus is the third bone of the firft row. It has its name from the Latin *cuneus*, a wedge. Its figure much reprefenting that of a wedge fticking between the two rows. It has a rough furface with a fmall tubercle upon it, which forms the greateft part of the cubital edge of the carpus; and four articular fides of which one is convex, which compleats the articular convexity of the carpus, one orbicular and internal, or on the concave fide of the carpus, on which the os pififorme is fet; and two others, which make an angle between them, one for the os femilunare, and the other for the os unciforme. *Winflow's* Anatomy, p. 83.

The *offa cuneiformia* of the tarfus are fituated before the os fcaphoides. The firft of them is the largeft, and the third the leaft; with the os cuboides, thefe form a fort of arch, which on the fide next the other foot is high, and low on the oppofite fide. In each of thefe bones we may diftinguifh the bafis, the apex, and four fides, one pofterior, one anterior, and two lateral; whereof one is internal, the other external. The firft bone is like a wedge contorted and bent. Its bafis is low down, unequally rounded, like an oblong tuberofity, ferving for the infertion of a tendon; the internal lateral fide, or that which is turned towards the other foot, is unequally convex, and rough, for the infertion

tion of ligaments. The external lateral side, or that next the second bone is unequally concave, and cartilaginous toward the superior and posterior edges. The largest portion of this side is articulated with the second bone. The rest toward the anterior edge is joined laterally to the second bone of the metatarsus. The backside is the least; it is cartilaginous and almost triangular, suited to the first of the three triangular surfaces of the os scaphoides. The anterior side is cartilaginous, large, and semilunar, the convex edge being turned toward the other foot, and by this the first *os cuneiforme* is articulated with the first bone of the metatarsus. The angle is turned upwards, and the obliquity of it occasions the anterior side to be the highest, and the posterior lowest. The second *os cuneiforme* has the basis upward, and the angle downward, and resembles a wedge more than the first: this basis is short and rough, for the insertions of ligaments. The backside is cartilaginous, and perfectly triangular, suited to its articulation, with the middle surface of the convex side of the os scaphoides. The anterior side is also cartilaginous, a little more oblong and articulated with the basis of the second metatarsal bone. The two lateral sides have, toward their superior and posterior edges, oblong cartilaginous surfaces, by which they are articulated with the first and third *ossa cuneiformia*; the rest of these two sides is a little depressed, and there, by small interstices, void spaces are left between the bones: this is every way the straitest bone of the three, its angles hid between the two other bones of the same name, and does not reach so low as theirs, which makes this part of the foot a little hollow. The third *os cuneiforme* has likewise its basis upward, and its angle downward. The basis is longer than that of the second, almost flat or very little convex, and rough for the insertion of ligaments; the angle runs down lower than that of the second bone. The backside is cartilaginous and triangular, that is of the same figure with the third surface of the convex side of the os scaphoides: the anterior side is, likewise, cartilaginous and triangular, but a little oblong, being articulated with the basis of the third bone of the metatarsus. The internal lateral side is broad, with two cartilaginous surfaces, one toward the posterior edge, the other toward the anterior; the first is for its lateral articulation with the second *os cuneiforme*; the second for its lateral articulation with the basis of the second metatarsal bone. The external lateral side is likewise broad, and toward its posterior edge has a large cartilaginous surface for its articulation with the os cuboides towards its anterior edge. There is a sort of void space for the passage of vessels, and sometimes a little cartilaginous corner for its lateral articulation with the fourth bone of the metatarsus. *Winslow's* Anatomy, p. 100.

Cartilages of the Os *femoris*. No part of the *os femoris* is covered, except the uniform convexity of the head, and the articular portion of the lower extremity. The trochanters have no true cartilage, what appears like it being only the remains of tendinous insertions; the cartilaginous substance, which to a certain age unites the apophyses to the body of the bone, does not belong to these, because it is only found in the time of youth, and in adults is converted into a bone. The cartilaginous matter, by which the head of the *os femoris* is cemented, deserves, however, to be observed here, because that apophysis has been separated by violent falls. The convexity of the head of the *os femoris*, all the way to its symphysis with the neck, is covered with a very smooth, shining cartilage. A little below the middle of this convexity, and something toward the back part, there is a depression in the shape of a crescent, the cartilage being here interrupted by the insertion of the internal articular ligament of the head of the *os femoris*. The cartilage which covers the lower extremity of this bone is exactly fitted to the semi-oval convexity of the inferior surface of each condyle, and to the pulley formed by their union. *Winslow's* Anatomy, p. 126.

Ligaments of the Os *femoris*. The *os femoris* is connected by its upper extremity to the os innominatum, and by the lower to the bones of the leg, by means of several ligaments. The ligaments of the upper extremity are two in number, one which surrounds the whole articulation thereof, with the cotyloide cavity, and one contained in the articulation. The first is termed the orbicular ligament of the head of the *os femoris*; the other the internal ligament; and to these may be, though but improperly, added a third, which is of the nature of a capsular ligament. The orbicular ligament is the most considerable, the largest, and the strongest, of all the articular ligaments of the human body; it is fixed quite round the border of the cotyloide cavity, and is made up of several sorts of fibres, and is much stronger and thicker in some parts than in others; the other, or internal ligament of the head of the *os femoris*, resembles a flat cord, and is composed of a bundle of flat fibres, closely interwoven. The ligaments of the lower extremity of the *os femoris*, by which this bone is connected with the leg, are six in number, one posterior, two lateral, two middle, or crucial, and the capsular. The crucial ligaments lie within the joint, and are fixed by one end to the back part of the notch, or opening, which parts the two condyles: these are surrounded by the capsular ligament, but all the rest lie on the outside thereof, being closely joined to it. Of the two lateral ligaments, one is internal, and broad, being fixed to the tuberosity of the internal condyle; the other is external, and narrow, and is fixed to the tuberosity of the external condyle. The posterior ligament is broad and thin, and being fixed a little above the convexity of the external condyle, it thence descends obliquely behind the great notch, and internal condyle. The capsular ligament is, as it were, glued to the three former, and is fixed quite round the inferior extremity of the *os femoris*; at a small distance above the anterior, lateral, and posterior parts of the cartilage, and above the posterior part of the great notch; and from the cartilage and notch, through the small space upward already mentioned, it covers the bone, and afterwards is inverted downward, to form the capsula for the mucilaginous liquor of the joint. *Winslow's* Anatomy, p. 126.

Os *frontis*. This is situated in the anterior part of the skull, and forms that part of the face which is called the forehead, from whence it has its name. Its figure is symmetrical, resembling a large shell almost round. Tho' this has always been looked upon as one bone, it is to be observed that it is sometimes found divided into two equal parts by a continuation of the sagittal suture; and this division is equally common to both sexes. Considered as one bone it may be divided into an upper part, which belongs to the crown of the head, a lower part which belongs to the basis of the skull, an anterior part which is the forehead, and two lateral parts at which the temples begin. Its two sides are the one external, which is in its greatest part convex, and forms the forehead; the other internal, which is concave in proportion. On the outside are observed the following eminences: Two superciliary arches, which form the upper edge of each orbit, or the supercilia; three risings not always equally apparent, one between the two arches, and the other two above them; which may be called the knobs of the forehead: five apophysis, one at the extremities of each arch, one between the orbits, which sustain the ossa nasi, and which in some subjects makes a part of the bony septum of the nose. This last may be called the nasal apophysis, the other four the angular apophyses. The external cavities are these two orbitary portions or vaults forming the upper portions of the orbits: a remarkable depression in each of these vaults above the external angle, which contains the lachrymal gland: a small depression above the internal angle, to which is fixed the cartilaginous pully of the great oblique muscle of the eye; two portions of the temporal fossæ; two little cristæ which form the anterior extremity of the great semicircular plane of the temples, on each side, at the edge of the superciliary arches, near the external angle; two superciliary foramina, which are sometimes double, and sometimes only notches; and, lastly, two holes or portions of holes, called the internal orbitary holes.

On the inside of this bone we see a sharp perpendicular eminence, called the frontal or coronal spine, directly opposite to the middle rising on the outside already mentioned; above this spine, a portion of the groove for the longitudinal sinus, which when the spine is wanting, runs down lower; below the spine a considerable opening, called the ethmoidal opening, because it contains the os ethmoides; the sides of this are always more or less cellular. Between this opening and the coronal spine, a blind opening, which in some subjects is wholly in the *os frontis*, in others, common to that bone and to the os ethmoides, and which seems to open into the frontal sinuses near the nose. The anterior fossæ of the basis of the skull, which receive the anterior lobes of the brain, and which, by juting out forwards, form the risings on the outside, before taken notice of: toward the lower part they are uneven, answering the inequalities of the lobes, and they are also a little raised, to make room for the orbits, sulci or furrows of the arteries of the dura mater, and sometimes other indeterminate depressions. Tho' this bone is in general composed of two tables, and a diploe, yet the orbitary vaults are very thin, and without any diploe. About the middle of the lower part of the bone, where the middle rising is commonly situated, the two tables are parted, to form two cavities called the frontal, or superciliary sinuses, and the separated portions are here each of them composed in some measure of two tables, or at least have two surfaces, which make in all four surfaces of each of the two tables.

The frontal sinuses are extended on the edge of the superciliary on each side, more or less, all the way to the superciliary perforations; below they are open, and communicate with the cells of the os cribrosum. They are commonly parted by a bony septum, which is often more or less uneven; sometimes also it is perforated, and sometimes part of it, sometimes the whole is wanting.

In different subjects these sinuses are observed to vary extremely both in extent and form; in some they are very small, and often very irregular, and their disposition cellulous; sometimes also they are entirely wanting, and in such subjects the cavity of the nose is larger than ordinary; one of them does not open into the nose but only communicates with the other.

The *os frontis* is articulated by suture with seven other bones, the ossa parietalia, os ethmoides, os sphenoides, ossa lacrymalia, ossa nasi, maxillaria, and the ossa malarum. It contains

tains the anterior lobes of the brain, and a portion of the longitudinal finus, and forms the forehead, the upper parts of the orbits, and a portion of the temples. *Winflow*'s anatomy, p. 21.

Cartilages of the Os *humeri*. The cartilage by which the hemifphere of the head of the *os humeri* is covered, is gradually thicker toward the middle, and thinner toward the edges. The four furfaces of the tuberofities, which appear cartilaginous in dry bones, ferve only for the infertion of the tendons of four mufcles, which move the *os humeri* on the fcapula. The channel, or finus, between the two tuberofities is partly covered by a thin cruft, which appears rather ligamentary than cartilaginous, and partly by a tendinous ftratum. The trochlea and fmall head of the lower extremity of the *os humeri*, are covered with a common cartilage, in which the fame proportion of thicknefs is obfervable, as in that of the upper extremities; and this holds indeed pretty generally of the convex articular cartilages: and the foffulæ near the pulley and fmall head, are covered with a thin cartilaginous and ligamentary varnifh.

Ligaments of the Os *humeri*. The capfular, or mucilaginous ligament, loofely furrounds the whole articulation of the fcapula with the head of the *os humeri*. The true ligament of this joint feems to be made up of two forts of ligaments clofely united together, *viz.* of a capfular ligament, which furrounds the whole articulation, and of feveral true ligaments which run over, and clofely adhere to the former at different diftances. On the body of the *os humeri* there are two particular ligaments, which may be termed the intermufcular, or lateral ones: they are long, flat, thin, but ftrong and narrow, fixed by one edge along the two lower thirds of the bone, and reaching to both condyles; they are broad, pretty tight, and are very narrow at the upper part, but broader toward the condyles.

The lower extremity of the *os humeri* is joined to the bones of the fore arm, by two fafciculi of ligamentary fibres, one fixed to the internal condyle, the other to the external. Each fafciculus is compofed of fibres clofely joined together near the condyle, but afterwards parting in diftinct bands like a goofe's foot. The capfular ligament is fixed to the condyles, and then covers them, and is afterwards fixed round both fides of this lower extremity above the foffulæ. The foffulæ are flightly varnifhed over alfo with a cartilaginous fubftance. This capfula feems to be ftrengthened by a ligamentary wall, the fibres whereof crofs one another in different directions, and appears larger and loofer when the mufcles are feparated from it, than when clofely united to them in its natural ftate. *Winslow*'s Anatomy, p. 139.

Os *humeri fractured*. Fractures of the *os humeri* are leaft dangerous when near its middle, and much worfe when near its upper or lower head. It fometimes happens, that the fractured ends of this bone keep their places, but much more frequently they are found flipped one over another; by which means the fractured limb is made fhorter than the found one: fometimes alfo, tho' much more rarely, it happens, that the divided ends of the bone recede from one another, by reafon of the weight of the arm, and by that means the fractured limb becomes longer than the found one. In fractures of this bone, where the ends of the divided bone have fliped one over another, as is ufually the cafe, there is required both force and fkill to reduce them, efpecially if the patient has tenfe nerves and larger mufcles, as is ufually the cafe in ftrong men. To extend the arm on this occafion, the patient muft be feated on a high ftool, and an affiftant muft lay hold of his arm firmly above the fracture, keeping his elbow gently bent; then the lower part of the arm beneath the fracture, is in like manner to be taken hold of, and the arm is to be gently extended forward, by endeavouring to remove eafily each part from the other, in a right line. The furgeon is then to take hold of the fractured part of the arm, and with both his hands reduce the fractured bones into their proper places, while the arm is kept in a proper ftate of extenfion by the affiftants; and when they are replaced, the limb is to be rolled up with the proper bandages. *Heifter*'s Surg. p. 127.

Os *hyoïdes*. Mr. Du Vernoy obferves, that the right fide of the *os hyoides* is fhorter than the left. Comment. Acad. Petrop. Tom. 7.

Cartilages of the Ossa *innominata*. Thefe are not fo numerous as might be imagined, on examining the bones in a dried fkeleton, where we are apt to think we fee the dried remains of cartilages on the crifta of the os ilium, on the tuberofity of the os ifchium, and on the grooves and notches which give paffage to the tendons of mufcles; but none of thefe incruftations are true cartilages, but for the moft part tendinous, aponeurotic or ligamentary, which fubftances being dryed, look more like cartilages than the true cartilages themfelves in the fame ftate. The true cartilages of thefe bones in adults are properly five in number, three of which are common, and two proper. The firft and principal common cartilage, is that which makes the fymphyfis of the offa pubis. This forms a kind of arch, which is more confiderable in men than in women; the two others join the offa ilium to the os facrum, but are thinner than that of the offa pubis. The proper cartilages are thofe which line the cotyloide cavities, in the edge of each of which there is a notch or opening between the anterior or inferior parts, and in the cavity itfelf there is a broad and fhallow depreffion, reaching from the notch beyond the middle part of the cavity; all the reft of the acetabulum is covered with a very white, fhining, fmooth cartilage, which terminates precifely at the edge of the cavity. *Winflow*'s Anatomy, p. 122. See Ilium.

Ligaments of the Ossa *innominata*. Thefe are of two kinds, common and proper: the common ligaments are thofe which go between thefe and the neigbouring bones, of which there are a confiderable number: One fuperior, inferted by one end in the internal labium of the pofterior part of the os ilium; one inferior and anterior, fixed by one end in the inner fide of the crifta of the os ilium, and by the other in the fuperior and anterior part of the firft falfe tranfverfe apophyfis of the os facrum. Several inferior and pofterior, fixed by one end along the internal labium of the tuberofity of the crifta of the os ilium, and by the other in the firft three falfe tranfverfe apophyfes: and to this muft be added the ligaments by which the os femoris is joined to the *os innominatum*. The principal proper ligaments are four: the two facro-fciatic, the obturator, and the inguinal, which fee under their proper heads; but befide thefe, there is another fmall, flat, and very ftrong ligament, which runs tranfverfely between the two angles of the cotyloide notch, and may be termed the proper, or tranfverfe ligament thereof. The elaftic border of the cotyloide cavity may likewife be reckoned among the ligaments: it is a fort of additional piece, ftrongly united to the edge of the cavity, but eafily yielding any way, on preffure. The two ligaments by which the os femoris is connected to the *os innominatum*, are alfo inferted in this bone; one of thefe ligaments furrounds the whole articulation, and the other is contained in it: the firft is called the orbicular ligaments, the other, tho' very improperly, the round ligament: the orbicular is very ftrong, and unequally thick, and furrounds the whole convex circumference of the fupercilium of the cotyloide cavity. The ligament which lies in the joint is not round, but is a flat cord, broad at one end, and narrow at the other, and is in fome degree of a triangular fhape. *Winflow*'s Anatomy, p. 122.

Os *innominatum fractured*. A fracture of this bone very feldom happens; but when it does, it is readily difcovered by the injury and fymptoms in the neighbouring parts, and is the more particularly dangerous, when the patient difcharges a brown bloody matter. In reftoring this bone, the patient muft lie down on his found fide; the bone muft be replaced with the hands, covered with compreffes, dipt in fpirit of wine, and kept on by the fpica bandages. Afterwards bleeding, with cooling and relaxing medicines, muft be ufed, and a thin diet obferved. *Heifter*'s Surg. p. 126.

Os *orbiculare*. This, in the carpus, is the fourth bone of the firft row. It has its name from the roundnefs of its figure, and is, for the fame reafon, by fome called *os pififorme*, and *os lenticulare*; it is, however, not perfectly, or regularly round; it has but one cartilaginous fide, which is irregularly orbicular, and the border, a circumference of which reprefents a kind of narrow collar. The reft of the bone is rough, convex, and irregularly round, making one of the four eminences, on the concave fide of the carpus. This bone, and the os cuneiforme, may be fuppofed to make a third row, diftinct from the other two. *Winflow*'s Anatomy, p. 83.

Nafi Ossa. See Nasi *offa*.

Palati Ossa. See Palati *offa*.

Parietalia Ossa. See Parietalia *offa*.

Pectoris Ossa. See Pectoris *offa*.

Os *facrum* (*Cycl.*) — As this bone is the bafis by which the whole fpine is fupported, it has by fome been called *os bafilare*; its figure comes near that of a long triangle, with the bafis upward, and apex downward. Anatomifts, in its defcription, divide it into the upper part, or bafis, the lower, as it is fituated, or apex; two fides, the anterior, or concave, and the pofterior, or convex; and two lateral parts, or edges. The pieces of which it is compofed in infants, called falfe vertebræ, are five in number, and are united together by cartilages, which in time almoft difappear, leaving only little ridges, or lines, more or lefs prominent in their places. The firft of thefe is much larger than any of the true vertebræ, but their fize diminifhes by very great degrees as they defcend; fo that the loweft which makes the point of the *os facrum*, has fcarcely the appearance of a vertebra. At the bafis, or upper part, of the *os facrum*, are two articular apophyfes, anfwering to the inferior ones of the laft vertebra of the loins. Below each of thefe apophyfes laterally is a large notch, and between them, we fee diftinctly enough the body of this firft falfe vertebra, which is like that of the lumbar vertebræ, being very much inclined backward; fo that the body of this firft falfe vertebra, as well as that of the laft true one, is longer before than behind; and from this obliquity it is that the *os facrum* and laft lumbar vertebra, form at their connection, a very confiderable angle. The lateral parts are broad at top, forming on each hand a large, irregular, cartilaginous furface, in the figure of a great S, and fometimes of a bird's head.

head. By these two sides the *os sacrum* is connected to the ossa innominata, by a cartilaginous symphysis. Between each of these lateral sides and the nearest posterior holes, there is a large rough depression, and under that another not so large. These depressions are often pierced by several holes, which lose themselves in the substance of the bone. *Winslow*'s Anatomy, p. 60.

Os *sacrum fractured*. When this bone is found to be fractured, the fragments are to be reduced into their proper places with the fingers; and if any part of it be depressed inwards, a finger dipp'd in oil or butter, and with the nail close cut off, must be introduced up the anus in order to thrust the depressed fragment into its proper place, to which it is to be directed externally by the other hand. This being performed, a sticking plaister is to be applied, and compresses dipped in spirit of wine over it, to be kept on by the T bandage, or the plaisters may be let alone, and only the compress and bandage applied. The patient must keep his bed a fortnight, lying on his sides; or if he will needs sit up, it must be on a chair without a bottom, that the bones may not be displaced by touching the seat. *Heister*'s Surg.

Os *sepiæ*, the cuttle-fish bone. See SEPIUM, *Cycl.*

OSSA *temporum*. See TEMPORUM *Ossa*.

Os-*tincæ*. The sides of the os-tincæ have been known to open together in women with child, and have been divided by incision, in order to extract the child. See Med. Ess. Edinb. Vol. 3. Art. 19.

OSSÆI, or OSSENI, a name sometimes given to the Jewish sect of religion called *Essenians*. *Hofm.* Lex. Univ. in voc. See ESSENIANS, *Cycl.*

OSCHEALIS *hernia*, a term used by some writers for a hernia of the scrotum.

OSCILLA, in antiquity, small images of wax or clay, made in the shape of men or women; which were consecrated to Saturn in order to render him propitious. *Hofm.* Lex. Univ. in voc.

OSCINES, among the Romans, an appellation given to such birds, from whose chattering or notes, omens and predictions were drawn. *Hofm.* Lex. Univ. in voc.

OSLEOM *iron*, in the wire-works, a particular sort of bars of iron wrought on purpose for the manufacture of iron-wire. These are small and square, and the first thing done with these, toward the making them into wire, is, the straining, or drawing them at a furnace to small rods, of the thickness of one's little finger; these they bow round, and deliver them to the wire-drawers. *Ray*'s Engl. Words, p. 132. See WIRE.

OSMERUS, in ichthyography, the name of a genus of fishes, of the malacopterygious, or soft-finned kind, the characters of which are these: The branchiostege membrane contains seven or eight bones on each side. The back and belly fins are placed at the same distance from the top of the snout; by which it is distinguished from the coregoni and salmons. The teeth are large, and are placed on the tongue in the palate and in the jaws.

The species of *osmerus*, enumerated by Artedi, are these: 1. The *osmerus* with seventeen bones in the pinna ani: this is the smelt or eperlanus of authors. 2. The *osmerus* with eleven bones in the pinna ani.

This is the little fish called *saurus* by Salvian, and by the people of Rome, named *tarantola*. It is about a span long, and somewhat thicker than a man's thumb. The scales are moderately large, and the pinna dorsi has twelve rays. *Artedi*, Gen. Pisc. 8.

OSMONDS, in our old writers, a kind of iron antiently brought into England. It is mentioned in Stat. 32. Hen. VIII. c. 14 *Blount*, *Cowel*.

OSMUNDA, in the Linnæan system of botany, the name of a genus of plants, of the fern kind, the characters of which are: That the seeds are produced in globose capsules which stand distinct, but are collected in a cluster on the branch, and open horizontally when ripe. The seeds are small, oval in figure, and very numerous: according to this character, that species of the fern kind usually called the *sensible polypody* of Muntingius, and ranked among the polypodies is, an *osmund*; for it produces clusters of globose capsules so large, that they are scarce to be conceived to belong to any thing of the fern kind. These also stand on particular stalks, not on the back of the leaf, which is also the case in the other species of *osmund*, as our common English kind evidently shews.

The characters of *osmunda*, according to Mr. Tournefort, are these: The flowers are not discovered, but the seeds are collected into clusters. The capsules in which they are enclosed, are of a spherical figure; and when ripe, they burst by the contraction of the fibres. The leaves resemble those of the fern's.

The species of *osmund*, enumerated by Mr. Tournefort, are these: 1. The common, or marsh *osmund*. 2. The *osmund* with lunated leaves, commonly called *moonwort*. 3. The *osmund* with multifid leaves, called *branched moonwort*. 4. The larger branched *osmund*, with lunated leaves. 5. The feverfew-leaved *osmund*, or *moonwort*. 6. The *osmund* with adiantum leaves. 7. The hairy lonchites-leaved *osmund*. 8. The great fern leaved *osmund*. 9. The lesser fern-leaved *osmund*. 10. The hart's-tongue-leaved *osmund* 11. The cut-leaved *osmund*, with broad dents. 12. The deeply jagged, and lightly hairy *osmund*. 13. The asphodel-rooted *osmund*. 14. The verticillated *osmund*. 15. The spear pointed lightly serrated *osmund*. *Tourn.* Inst. p 547.

OSOSOR, a word used by some authors as a name for opium. See the article OPIUM.

OSPRION, a word used by some authors for a bean, which is its proper and determinate signification; but by some authors it is extended to all sorts of pulse.

OSSA. See the article Os.

OSSELET, in the manege, is a very hard excrescence, resembling a little bone, on the inside of the knee, (and never on the outside) appearing to be of the same substance with the rest of the knee, and only distinguishable from the knee by its descending a little lower.

OSSERVANZA, in the Italian music, is used for singing or playing with care; that is, executing a piece of music justly and exactly as it is marked, without adding or diminishing. *Broff.* Dict. Mus. p. 22.

OSSICULA *auditoria*, in anatomy, are four little bones contained in the cavity of the tympanum, or barrel of the ear, and assisting to the hearing; they are denominated from things they have been supposed to bear a resemblance to, the malleus, incus, stapes, and os lenticulare, called by others the *os orbiculare*; each of which see under their proper heads.

OSSICULA *musculorum*, in ichthyology, a name given by authors to those oblong and slender bones which are situated in the flesh of some kinds of fish between the muscles; these, in the anterior part, and especially near the head, are of a forked shape; but in the hinder part of the body, they are usually simple and slender. These sorts of bones are found in the following kinds of fish: 1. In all the cyprini. 2. In the esoces. 3. In the clupeæ. 4. In the eels 5. In the coregones. 6. In the osmerus. 7. In the salmon kind. 8. In mackrell. And 9. In the ammodytes or sand eel. In the five last, these bones touch the spine at one end, but in the others they no where come near it.

The use of these loose bones seems to be, to strengthen and support the muscles, that by this means they may be able the more forcibly to move the body, and turn it about: they are peculiar to fish, no land animal having them. *Artedi*, Ichthyol.

OSSIFICATION (*Cycl.*) — Dr. Nisbet's opinion of *ossification* is, that in the blood, or a fluid secreted from it, there is an ossifying juice consisting of particles which are not apparent: that whenever nature designs an *ossification* between membranes, or within a cartilage, she occasions a more than usual afflux of this fluid; which so much distends the vessels which were before invisible, as to make them capable of receiving the red globules of blood, which is always to be seen near to the place where *ossification* is begun. In this blood, gritty bony particles are to be felt by the point of a knife; which have been formed by the attraction and cohesion of the particles of the ossifying juice obstructed, along with the other grosser fluids, in the beginning of the vessels prepared to receive refuent juices. The blood being capable of forming fine membranes, the membranous parts of a bone, which act as a gluten to keep these particles and fibres together, if there be any such, that do not arise from the coats of its vessels, are produced by a cohesion round the cretaceous particles of a part of the fluid, in which they were generated and contained. Thus the membranes of cartilages serve as a bed between, or within which the bony particles are deposited, or shoot; but without any intermixture of the particles of the bone and cartilage, or continuation of the fibres of the one substance to those of the other, as is evident in cartilages containing bones kept long enough in water, and then slit; for the bone will, as soon as the large vessels that enter its substance are divided, slip as easily, if not easier, from it, than an acorn does out of its cup: and there is a smoothness and polish of the parts of both cartilage and bone, which shew there is no conjunction of the fibres of the two substances While the bones are encreasing within cartilages, the cartilages are extended and spread out; by which, with the pressure which they suffer, and the great influx of various fluids, and the nutricious matter being hindered to flow freely into them, they decrease continually; and at last may truly be said to be entirely destroyed. Med. Ess. Edinb.

Dr. Buddeus endeavours to prove, that the preternatural *ossifications*, which are commonly said to be formed in different parts of the body, do not deserve that name; for that these hard substances have scarce any other properties of bone, except whitenefs and hardness. *Misc.* Berol. Tom. 5. pars 2. §. 1.

OSSIFRAGUM, in botany, a name given by Bartholine, and some other writers, to a peculiar kind of grass, growing in some parts of Norway. It comes up early in the spring, before any other grass, and the cattle are tempted to eat it; but it emaciates them, and makes them sickly; their back bones become protuberant if they feed any time on it, and their legs so weak that they can hardly go. The remedy among

among the country people is a very odd one. They collect the bones of different animals, and break them into small pieces. The cattle greedily devour this sort of food when offered them in this disease, and there follows a sort of driveling at the mouth for a considerable time, after which they become well It is possible there may be much error in this story. The kingdom of Norway is full of mines, and the effluvia of these may be the occasion of the cattles illness, and the ceasing of these effluvia their cure; for it is not probable that either of these effects should be owing to the grass or the bones. *Barthol.* Act. Med.

OSSIPAGINA, in botany, a name given by Arnobius and some other of the old Greek writers to the consolida-major, or greater comfry. It had this name from its supposed quality of agglutinating broken bones on being taken internally. The Greek writers have sometimes called this plant *pecte*.

OSTEOCOLLA, (*Cycl.*) a substance used in Germany in cases of fractures, giving it inwardly to bring on a callous; but so inaccurately described by authors, several different species of the crustaceous spars having been described under its name, that it is not easy to ascertain what it truly and regularly is. Dr. Hill, from the inspection of what is now universally received in Germany as such, which answers very well to the accounts given of the substance by those who have first recommended it in medicine, has ascertained the name to a peculiar species of crustaceous spar of the terrene kind, which he has described under the name of *cibdeloplacium crassius, exalbo pallide fuscum, durum, superficie scabra*, or hard, pale brown, thick crustaceous spar, with a rough surface.

This is found in long, thick, and irregularly-cylindric pieces, which are usually hollow, but are sometimes filled up with a marley earth, and sometimes contain within them the remains of a stick, round which the *osteocolla* had been formed: but tho' it is plain from hence, that many pieces of *osteocolla* have been formed by incrustation round sticks, yet the greater number are not so; but are irregularly tubular, and seem formed of a flat cake, rolled up into a cylindric shape. The crusts of which these are composed do not form regular concentric circles round the internal cavity, as must have been the case had they been formed by incrustation, but shewing plainly that they were once so many thin strata, composing a flat surface, which has afterwards been rolled up as one might do a paper three or four times doubled, into two, three, or more spiral lines; in which case, each single edge of the paper would be every where a regular part of a continued spiral line drawn from a given point; but they would by no means be so many detached concentric circles.

The *osteocolla* is found of various sizes, from that of a crow-quill to the thickness of a man's arm. It is composed of spar and earth, and is found, both in digging and in several brooks, in many parts of Germany and elsewhere. *Hill's* Hist. of Foss p. 359.

Osteocolla is called *hammosteus* in many parts of Germany. It has this name in these places from the observation of its always growing in sand, never in clay, or any solid soil, nor even in gravel. Where a piece of it any where appears on the surface, they dig down for it and find the branches run ten or twelve feet deep. They usually run streight down, but sometimes they are found spreading into many parts near the surface, as if it were a subterraneous tree, whose main stem began at twelve foot depth, and thence grew up in a branched manner, till met by the open air. The main trunk is usually of the thickness of a man's leg, and the branches that grow out from it are thickest near the trunk, and thinner as they separate from it. The thinnest are about the size of a man's finger. The people employed to collect this *osteocolla* when they cannot find any mark of it on the surface, search after the specks of white, or little lumps of whitish soft matter, which they find lying in different parts on the top of the sand. These always lead them either to a bed of perfect *osteocolla*, or to some in the formation. If they miss of the substance which they seek after, they still find a substance like rotten wood; which, when traced in its course, is found to proceed from a main trunk, at the depth of that of the *osteocolla*, and to spread itself into branches in the same manner. The diggers call this substance the flower of *osteocolla*, or *hammosteus*.

The *osteocolla* found in the earth is at first soft and ductile, but in half an hour's time, if exposed to the air, it becomes as hard as we find it in the shops. The method to take up a perfect piece for a specimen, is to open the ground, clear away the sand, and leave it so for an hour or thereabouts: in this time it will harden, and may be taken out whole. It is certain, that the *osteocolla* is produced at this time; for, if a pit be cleared of it, there will more grow there in a year or two, but with this difference, that it will be softer and will not harden so easily in the air as the other. What the rotten substance resembling the decayed branches of trees is, it is not easy to say, unless it really be such: but the opinion of the common people, that it is the root of something, is absurd; because its thickest part always lies at the greatest depth, and the branches all run upwards. The *osteocolla* is a marley spar, which concretes round this matter; but what it is that determines it to concrete no where in the same ground but about these branches, is not easy to say. The rottenness of this substance which forms the basis of the *osteocolla*, renders it very liable to moulder and fall away; and hence it is that we usually see the *osteocolla* hollow. Sometimes it is found solid, but in this case there will be found to have been a vegetable matter serving as its basis, and instead of one branch, it will be found in this case to have concreted about a number of fibres, the remains of which will be found in it on a close examination. *Phil.* Transf. N. 39.

OSTEOCOLLA-*flower*. See the article FLOWER.

OSTEOCOLLA-*roots*. See the article ROOT.

OSTEOCOLLON, in botany, a name given by some authors to the great comfry. *Ger.* Emec. Ind. 2.

This name was given by some of the old writers to the symphytum, or comfry, from an opinion that its agglutinating quality reached to the bone, and that it was of great service taken internally in cases of fractures.

OSTEOGONY. See the article OSSIFICATION.

OSTEOLOGY (*Cycl.*)—There are properly two kinds of *osteology*, one of which is to be learned from bones dried and prepared by boiling, and the other from the bones of a dead subject, as they are naturally connected with each other. Both these methods are very necessary for the practice of physic, and for the exact knowledge of the human body. By examining dry bones, however, we can only learn their exterior forms, their situation, and the connection which they may have with one another; but when we consider them as joined together in a dead body, we are in a condition to observe many other things in regard to them, very useful in physic: because their connections with one another by cartilages and ligaments, and by the diversity of articulation, are sometimes very different in the dry from what we see them in the fresh bones; there are, for instance, in dry bones, certain cavities which appear to be cotyloide, because they are divested of their cartilages; but in fresh bones, they are found to be glenoide, their cavities being filled with cartilages. And, on the other hand, some cavities appear to be glenoide in the skeleton, which are cotyloide in the body, their cavities being augmented by cartilaginous supercilia.

The exterior form and qualities of bones are much better demonstrated also from fresh subjects, than from prepared bones; because they loose a great many things in boiling, such as the cartilaginous bodies, the periosteum, the mucilaginous substance found between them, and the marrow contained in their cavities; all which may be shewn in a fresh body, but cannot be seen in a skeleton. *Riolan.* Encheiridion Anatomicum.

OSTINATO, or *Contrapunto* OSTINATO, in the Italian music, is much the same with *Perfidia*. See PERFIDIA, *Cycl.*

OSTRACION, in the Linnæan system of zoology, the name of a large genus of fishes of the general order of the branchiostegi. The characters which distinguish the fish of this genus, are, that they have no belly-fins, and their skin is always hard and often prickly. Of this genus, besides the *ostracion*, commonly singly so called, are the orbis, hystrix, atinga, &c. *Linnæus's* System. Naturæ, p. 52.

The characters of the *ostracion*, according to Artedi, are these: there is no branchiostegi membrane; the figure of the body is particular, being globose, or spherical, or roundish, oval or oblong and square, or finally conic; the skin is very hard, and usually beset with rigid and hard spikes, either on the whole body or on some part of it, but in some species it is wholly smooth; there are no belly-fins; the number of the others is five, there are two pectoral or lateral fins, two others are on the back, the other at the anus and the tail; the mouth is small; the teeth are large; and the eyes are covered with the common skin of the head; there are on each side two foramina for the nostrils, near the eyes; the lips may be drawn back, but in their natural state they cover the greater part of the teeth. *Artedi*, Gen. Pisc. 39.

The species of this genus are these. 1. The oblong square *ostracion*, with four large tubercles on the back: this is the piscis quadrangularis maximus of Ray. 2. The oblong square *ostracion*, with a gibbous back: this is covered all over the body with beautiful hexagonal figures. 3. The oblong square *ostracion*, with a sharp snout, and with several spots on the back and head; there is a specimen of this in the cabinet of Sir Hans Sloane. 4. The square *ostracion*, variegated with a great number of spots: the spots of this are rounded, and are of various colours. 5. The triangular *ostracion*, with two spines on the head, and two more on the lower part of the belly: this is covered with hexangular and other radiated bodies instead of scales. 6. The triangular *ostracion*, with two spines near the head, and one long one on the upper part of the body near the tail: this is very beautifully spotted. 7. The triangular *ostracion*, with two spines in the lower part of the belly, and covered with hexagonal bodies, with prominent edges: this is the piscis triangularis of Clusius and other authors. 8. The triangular *ostracion*, spotted all over and covered in many places with tubercles, having two spines in the lower part of the belly: the spots of this fish are of various colours, and they are larger than the tubercles. 9. The triangular *ostracion*, with hexagonal and radiated tubercles, and with

with two spines in the lower part of the belly. This is smaller than most of the others. 10 The triangular *ostracion*, covered with innumerable small tubercles, and having no spines.

The species hitherto enumerated, have all a considerable number of teeth, the following species have only four: 1. The round *ostracion*, with four teeth, covered every where with small spines. This is the orbis of some authors. 2. The spotted *ostracion*, covered all over with small and very thick-set spines. This is the orbis asper of authors. 3. The oblong and compressed *ostracion*, with a roundish belly, and with spines only on that part. This is the orbis lagocephalus of Grew. The following species of *ostracion* have no teeth at all, but have bony jaws: 1. The sphæric *ostracion*, covered all over with thick-set three cornered spines. This is the atinga orbicularis of authors; and is about the size of a goose's egg. 2. The roundish *ostracion*, covered every where with flat and short spines, but with the belly smooth. This is the orbis spinosus of Clusius. 3. The roundish *ostracion*, covered with short three-cornered spines, set at distances from each other. This is the orbis reticulatus of Lister. 4. The oblong roundish *ostracion*, with tubercles on each side, and with a very long back fin. 5. The roundish *ostracion*, with numerous thick-set spines of a three-cornered figure at the base. 6. The conic oblong *ostracion*, with long cylindric spines on all parts of the body, but principally on the sides. This is the histrix piscis, or porcupine fish of authors. 7. The oblong *ostracion*, with long and cylindric spines covering all parts of it, but principally the head and neck. 8. The oblong smooth *ostracion*, with a long head, and with a body adorned with various figures. This is the orbis testudinis capite of Ray. 9. The compressed roundish rough *ostracion*, with horizontal pectoral fins, and with four foramina in the head. This is the fish called by authors the *mola*, or *sun-fish*. *Artedi*, Gen. Pisc p. 39.

Willughby uses the word *ostracion* for a fish caught sometimes in the river Nile. It is very thick in proportion to its length, and of a somewhat pentangular form. It is usually of about a foot long, and is covered with a shelly coat or skin, not less strong and hard than many of the shell-fish kind. It has a strait, not forked tail, two fins a little above it, and two more higher up the body. Its eyes are white; its mouth small; and it is all over of a pale whitish hue. *Willughby's* Hist. Pisc. p. 148.

OSTRACITES, (*Cycl.*) in natural history, a name given by authors to the fossile *oisters*, common in many parts of England. These are of various shapes and kinds; and the name is by some authors made to signify, the shell itself, when preserved in its native state and condition; as is the case with those found about Woolwich and Blackheath; and by others, the stones cast or formed in those shells, or in cavities from whence they have been washed away and dissolved: in both these cases, the stone carries the exact resemblance of the shell, even in its nicest lineaments; in the first case, carrying every mark of the inside; in the other, of the outer surface. *Hill's* Hist. of Foss.

We have this stone in great plenty in many parts of England; and it is very famous, in some places, for its virtues in cases of the gravel, and the like complaints, as mentioned in the *Cyclopædia*. See Tab. of Fossils, Class 9.

This virtue of a fossile, not generally known, may make it necessary to add such an account of it, that it may not be mistaken by those who are willing to try it. It is the *ostracites maximus rugosus asper*, the greatest rough and uneven *ostracites*, excellently described by Lister. It burns to lime as the spars and selenitæ do, and yields no volatile salt on a chemical analysis. The common oister shells fresh taken and used, do not afford more than half a scruple of a liquor moderately urinous, from a quarter of a pound of the shells; and probably, on being long exposed to the weather, they would loose even that, and yield no more, on trial, than the *ostracites*.

These fossile oister-shells are more beaked at the part where the hinge is, than the common oister; and in their specific gravity, they are heavier than fresh oister shells, and approach to the nature of the selenites.

It is to be observed, that all the fossile shells, and particularly the *lapides judaici*, or Jew's stones, which have been the spines of sea echini, have been esteemed diuretics, and good in the stone and gravel. Among the antients, Dioscorides, Pliny, and all the rest recommend them highly. Phil. Transf. Nº 251.

OSTRACODERMATA, a term used by Aristotle, to express that class of shells which we call *testaceous*, in opposition to the crustaceous animals, or malacostraca. The definition Aristotle gives of this class of animals is, that they are soft within, but hard without; that their shells may be bruised or broken; but their parts cannot be torn from one another, as they can in the crustaceous kind, such as the lobster; whose shells covering the legs, body, tail, &c. being so many distinct pieces of shell, and only joined by membranes, may be torn asunder by pulling till those membranes give way. The echini marini, or sea urchins, have been generally allowed to be testaceous animals; and even Aristotle himself, the author of the distinctions, as well as later writers, have arranged them in this manner; but it is plainly erroneous; for they have all the characters of the crustaceous kinds, when strictly examined; and their shells are, as in the lobster, made up of several pieces connected by membranes, and divisible one from another, by tearing or pulling without breaking; and every one of the spines is a sort of leg, moveable every way upon its socket, and joined in the same manner only by a membrane: Gesner ranks them among the testaceous fishes, tho' he acknowledges that Rondeletius, whom he usually follows, classes them among the crustaceous kinds; reckoning them after lobsters and crabs. Pliny also is of this opinion, and differs in it from most others of the antients: yet the place of these fishes has scarce yet been ascertained. A shell is properly enough the name of the covering of these, as well as of the other, or testaceous fishes; and in the testaceous kinds, may be defined to be a hard substance, covering an entire animal, or at least one whole side of one without joints or ligatures: and, on the other hand, a crust may be defined to be such a hard substance as covers only one particular joint of the enclosed animal; so that in the whole crustaceous fish, there are as many shells, if we may be allowed to use that word in the general sense, on every animal, as there are joints in that animal. The scalops, oysters, wilks, &c. give us familiar instances of the first kind or shells, properly so called; and the crabs and lobsters, of the latter kind or crusts. The first, therefore, are properly testaceous animals; and the latter crustaceous: and in this case, whoever examines the sea echini in their exact and perfect state, will find that they evidently belong to the crustaceous, not to the testaceous class.

The echini, lobsters, &c. may be called *multi testaceous*, or many-shelled; and the others *simply testaceous*, *bitestaceous*, and by other terms, expressing the characters of those few genera which have more shells than two: and as in the scaly fishes, every separate scale has its separate muscle, to which it is answered by a particular tendon; so all the crustaceous animals have particular muscles, which are separately inserted one into every crust; and all these crusts are also connected to each other by common membranes, which are in a particular manner necessary, as they do not lie one upon another as the scales of fishes do, and by that means secure and strengthen each other. Phil. Transf. Nº 219. p. 199.

OSTREA, the *oister*, in natural history, the name of a very large genus of shells, the characters of which are these: It is a bivalve shell, of a coarse external structure, and dirty appearance; each shell being composed of a great number of laminæ not nicely closed down upon one another. It is in some species smooth, in others striated, tuberous, or prickly; usually flat, but sometimes globose, plicated, and wrinkled into sinuses. The lower shell being always deeper than the other. Aldrovand supposes this genus of shell fish obtained the name *ostreum*, from the Greek ὀστέον, a bone, as they are of a bony hardness. See Tab. of Shells, Nº 17.

Most authors have confounded the two genera of *oisters* and chamæ together, tho' there is an obvious and invariable distinction. The *oister* is rough, and has a sort of beak; and notwithstanding the roughness of both shells, it always shuts very evenly and firmly: add to this, that one of its shells is flat, the other convex; and is thus absolutely distinguished from the chamæ. Hist. Nat. Eclair. p. 313.

Oisters in their growth become fastened to every solid substance which they happen to come into contact with; and rocks, small stones, wood, sea-plants, and a thousand other things are found at times with *oisters* adhering to them, whose shells have fitted themselves to the form of the thing itself, and left their natural shape. The people who fish for, and trade in *oisters*, pretend to distinguish two kinds; one which is fecund and will breed; the other which is barren. They say, they distinguish these by a little black fringe, which always surrounds the good breeding *oisters*.

The way to make *oisters* green is, to put them into small pits where the water is about three foot deep, and where the sun has great power; in these they become green in three or four days.

The species of *oisters* being very numerous, they may be better understood by being arranged under some general heads.

I. Some *oisters* are plane and smooth.

Of these we have the following species: 1. The common *oister*. 2. The naturally green *oister*. 3. The oriental *oister*. 4. The pearl *oister*, or beiberis; this is by many authors described as a peculiar genus, under the name of *concha margaritifera*; but it is a true species of *oister*. 5. The green-onion-rind *oister*. 6. The rose-coloured-onion *oister*. 7. The yellow-onion *oister*. 8. The amber-coloured-onion *oister*. 9. The striated-onion *oister*. 10. The saddle *oister*. 11. The violet-coloured saddle *oister*. 12. The pintado *oister*, whose spots resemble those of the pintado, or guinea hen. 13. The pond *oister*. 14. The red-striated japan *oister*. 15. The swallow *oister*.

II. Some *oisters* are smooth, yet foliated on the surface.

Of these we have, 1. The malleum, or brachiated *oister*; called *the mallet-headed oister*. 2. The small plicated *oister*, called *the cocks comb*, or *the hog's ear oister*. 3. The hedge-

hog

hog *oiſter*: this has its ſhells round, with tubular ſpines. 4. The leaf *oyſter*. 5 The tortuous *oiſter*, called by many the leg *oiſter*. 6. The thigh *oiſter*.

III. Some *oiſters* are of a globoſe form, and carry ſpines on their ſhells.

Of theſe we have the following ſpecies: 1. The round-ſpined *oiſter*. 2. The *oiſter* with flat ſpines. 3. The fire-coloured *oiſter*, with large ears. 4. The white-pointed rock *oiſter*: this is uſually found adhering to ſtones. 5. The bridge *oiſter*: this alſo is uſually found affixed to ſtones or pebbles, in ſuch a manner as to repreſent a bridge; the ſeveral ſmall ſtones its ſhell ſpreads over making the piers. 6. The furr and roſe-coloured *oiſter*, with flat white ſpines. 7. The coral *oiſter*. 8. The medal *oiſter*, ſo called from the place near Bourdeaux, where it is found. 9. The *oiſter* with red and blue ſpines. 10. The cluſter *oiſter*, with variegated ſhells.

IV. Some *oiſters* are of a globoſe figure, and jagged with high raiſed laminæ.

Of theſe we have the following ſpecies: 1. The great foliated *oiſter* of Rumphius, called by ſome the Placenta foliacea. 2. The ſtriated orange *oiſter*, from the Baltic. 3. The ſquammoſe or ſcaly *oiſter*, called Scandebec by Rondeletius. 4. The ſquammoſe *oiſter*, with tubular ſpines. 5. The yellow ſquammoſe foliaceous *oiſter*: this ſpecies is often found adhering to the ſeveral kinds of coral, and is not unfrequently itſelf covered with balani or center ſhells.

V. Some *oiſters* are oblong and umbonated.

Of theſe we have the following ſpecies: 1. The ſmooth ſpondylus or aſs-foot *oiſter*. 2. The rugoſe but not ſpinous *oiſter*. 3 The white-plated *oiſter*, with a digitated edge covered with roſe-coloured ſpines. 3. The yellow-plated *oiſter*, variegated with red and white. 5. The gaidaron *oiſter* of Rondeletius. See OYSTER.

OSTRICH, *ſtruthio*, in zoology. See STRUTHIO.

OSTRUCIUM, a name given by the Latin writers of late ages to the plant called ſmyrnium and oluſatrum. Macer calls this plant caulis ſylveſtris, and has given to it the virtues attributed by the antients to the ſtruthion, ſuppoſing theſe to be the two names of the ſame plant; but this is evinced to be an error by the writings of all the antient Greeks. Theophraſtus in particular ſays, that the ſtruthion is a prickle or thorny plant. This alone is ſufficient to prove it can have no relation to the *oſtrucium* of the later authors, or Alexanders, which is a ſmooth umbelliferous plant.

This inaccuracy of the writers who collect their accounts from the ancients, is ſometimes of bad conſequence; ſince thoſe who are unable to have recourſe to the original authors, are miſled ſo far as to ſuppoſe the virtues of one plant may be found in another. See the article SMYRNIUM.

OSYRIS, in botany, the name given by Linnæus to a genus of plants, including the caſia of Tournefort, and other authors. The characters are theſe: it produces both male and female flowers. In the male flowers the perianthium is one leaved and hollow, and is divided into three ſegments, which are all of the ſame ſize, and of an acute oval figure. There are no petals, and the ſtamina are three ſhort filaments. The antheræ are ſimple. In the female flowers the cup is of the ſame figure as in the male, but is very ſmall and ſtands upon the germen of the piſtill, and remains on it a long time. There are no petals. The germen of the piſtill is roundiſh, the ſtyle is very flat, and the ſtigma roundiſh. The fruit is a round berry, having one cell, in which is contained a ſingle bony ſeed. *Linnæi* Gen. Plant. p. 472. *Tourn.* 448.

OSYRIS is alſo uſed by ſome authors for the linaria or toad-flax. *Ger.* Emac. Ind. 2.

OTAPULLI, in botany, a name given by ſome authors to the tree which produces the *gamboge*, or *gutta gamba* of the ſhops. Hort. Malab. Vol. I. p. 41.

OTENCHYTES, a name given by ſome authors to a ſyringe made for injecting into the ears

OTHOMAN. See the article OTTOMAN.

OTHONE, *ὀθόνη* & *ὀθόνιον*, among the antients, a kind of linnen garment worn by women. *Pitiſc.* in voc.

OTHONI, a word uſed by chemical writers for what they otherwiſe call the *mercury of the philoſophers*, or *philoſophic ops*.

OTHONNA, the name given by ſome authors to a ſtone found in Ægypt, and deſcribed to be always in ſmall pieces, and of the colour of poliſhed braſs: probably it is ſome ſpecies of the *pyrites*.

OTHONNA, in botany, a name given by ſome authors to the *african marygold*. *Ger.* Emac. Ind. 2.

OTIS, in zoology, the name of a large bird, ca'led in Engliſh the *buſtard*. The *otis* is called *tarda* and *otardes* by ſeveral authors. See Tab. of Birds, N° 28.

In the Linnæan ſyſtem of zoology, the *otis* makes a diſtinct genus of birds of the order of the Gallinæ; the diſtinguiſhing characters of which are, that the feet have only three toes each, and thoſe all placed before, and the head is not adorned with a creſt or any other ornament. *Linnæi* Syſtem Nat p. 47.

It is of the ſize of the common turkey, its beak is like that of the common gallinaceous fowls; its head and neck are grey; its belly white, and its back variegated with tranſverſe ſtreaks of red and black; it has no hinder toe, by which, and by its ſize, it is eaſily diſtinguiſhed from all the reſt of the gallinaceous kind. It feeds on herbs, and eats very greedily the leaves of dandelion, and particularly on the ſeeds of hemlock, which ſeems a very ſtrange food It is frequent in many parts of England, where there are large heaths and plains: they are very bad fliers, and very difficultly raiſe themſelves up from the ground; but they are extremely ſhy, and if they ſee a man at a very great diſtance, they immediately eſcape as faſt as they can Their fleſh is eſteemed. *Ray's* orinthology, p. 129.

OTITES-*digitus*, the *ear-finger*, a name given by authors to the finger next the little one.

OTOMO, in zoology, the name of a bird of the lagopus kind, called alſo *colmeſtre*, and by the Germans, *ſteinhun*, that is, *ſtonehen*. It is of the bigneſs of a tame pigeon; its belly and wings are white, with only a very few browniſh feathers; its head, neck, and breaſt are variegated with brown feathers, and the upper part of the neck with black and white; its beak is very ſhort and black, and it has fine red granulated membranes over its eyes; its tail is principally black, but is variegated with brown and white; and its legs and feet are feathered to the ends of the toes. *Geſner* de Avibus.

Mr. Ray is of opinion, that this is the ſame ſpecies of bird, with the common white *lagopus*, it being no way different but in colour, and thoſe birds being ſaid to change colour in the ſummer months. It is caught on the mountains of Germany, and is a very delicate bird for the table.

OTTER, in zoology. See the article LUTRA.

OTTERPIKE, in zoology, the name of a large ſpecies of the *draco-marinus*, or *ſea-dragon*, called in Engliſh the *weaver*: it is not greatly larger than the *weaver*, but is of a great variety of beautiful colours; and inſtead of the yellow ſide-lines which that fiſh has, this has rows of large black ſpots. *Willughby's* Hiſt. Piſc. p. 288.

OTTOMAN, or OTHOMAN, an appellation given to the empire of the Turks, or rather to their emperors, from *Othomannus*, or *Oſmanhus*, the firſt prince of the preſent family. See *Hoffm.* Lex. in voc.

OTTUPLA, in the Italian muſic, ſignifies *octuple*, or the meaſure of four times; it is marked with a ſemi-circle, C; and ſometimes thus:  when it is to be played very quick. In this time, eight quavers are contained in a bar. But it often happens, that ſuddenly, inſtead of two quavers for every time of the bar, three are required; this is called *dodecupla*. 'Tis enough to place a 3 over three quavers, or notes of equal value, to ſhew that the meaſure muſt be changed; and when this three is omitted, it ſufficiently demonſtrates the meaſure to be *ottupla* again: this makes what is called by the Italians *ottupla è dodecupla*, thus:

ottupla. *dodecupla.*

Corelli, in the laſt movement of his tenth ſonata, opera terza, very often uſes an 8 after the *dodecupla*, to ſhew, that the triple there is changed to common time.

OTUS, in zoology, the name of the common *horn-owl* of the ſmaller kind, in many reſpects different from the great *horn-owl* or *eagle-owl*. It is a moderately large bird; its beak is black, and its face ſurrounded with a double circle of feathers, the outer of which is variegated with fine black, white and brown lines, and the place where both circles join is all the way black; its belly and the feathers on its legs are brown; its throat and breaſt are covered with feathers black in the middle, with white and brown edges; its long wing feathers are ſpotted with black; its horns, or feathers that riſe up from its ears, are black in the middle and variegated with brown and white at their edges; and its tail is grey above and yellow underneath, and is variegated with ſeveral tranſverſe black ſtreaks; its feet are hairy down to the toes. It is common in Italy, and is ſometimes caught in ſome parts of England, and generally fixes its abode in mountainous places. *Ray's* Ornithol. p. 64.

OVA (*Cycl*)—The ingenious Dr. Kerkring was the firſt who advanced the generation of all animals to be from *ova*, and that even man himſelf was produced out of an egg. The ſyſtem occaſioned great raillery at the time, and the author found himſelf under a neceſſity of publiſhing all his obſervations by way of juſtification. The *eggs* which he found in the teſticles of all females countenanced his opinion, and he gave figures of the parts in their natural ſituation, and of the eggs which he found in women from the age of eighteen to more than forty, in his different diſſections. Among the other creatures he examined, he found many ſmall eggs in the teſticles of cows, and other creatures of the viviparous kind. He gives an account of one *egg* which he had an opportunity of opening about four days after it had fallen into the matrix of a woman, and in this he could perceive the marks of the little embryo, the head of which was diſtinctly to be ſeen from the body. Another *egg*, which he had an opportunity of opening at about a fortnight after conception, afforded him a ſight of a little fecundine. The membrane chorion divided in four places, and the amnion d vided in the ſame manner the navel ſtring, by which the child was faſtened to the ſecundine;

cundine; and in the child itself, the face at this time began to be formed, and the features were distinguishable, and the principal parts of the body easily traced. At longer periods from the time of impregnation, the features and lineaments of all the parts appear more and more strong; and the author has given accurate descriptions of the progress of the fœtus toward perfection, and figures of it at three, four, five, and six weeks after conception, at which last time all is very fair and plain.

The *ova* in which these lineaments of the fœtus are found after conception, are themselves formed without such lineaments, not only in married women, but in maids who have had no commerce with men at all; and it is the same in creatures naturally oviparous. The pullet will even lay her eggs without any intercourse with the cock, but then they will have none of the lineaments of the young fowl, which are found in the eggs laid after treading, and enlarging every day after the beginning of the incubation.

The eggs found in the testicles of unmarried women are generally of the size of a pea, round, and containing a glutinous liquor, which will harden, on boiling, in the same manner as the yolk and white of a common egg. The taste is rather unpleasant than insipid, and they are inveloped in two skins, which after they are fallen into the womb become two membranes, called the amnion and chorion, which enlarge as the contents enlarge.

Fallopius observed these eggs in women before the time of Kerkring, but it was this author who carried on the conjectures of the other into a sort of certainty, and added proofs to what he had first hinted from a number of experiments; and Wharton, in his account of human generation, is of opinion, that the semen penetrates into the testes of the female by means of the Fallopian tubes; in which case, the impregnation is in this instance performed exactly as in others of the oviparous creatures, and the whole difference amounts to no more than this, that in some the impregnated matter loses its figure of the *egg* before it is excluded the parent; but in others, it retains it till it is not only put forth out of the body, but hatched by its genial heat afterwards.

The egg being impregnated by the semen admitted this way, descends into the womb, and there becomes, in a few days, of the biggness of a cherry; and afterwards increases, as we have already observed. This author having an opportunity of opening the body of a woman who had died suddenly about four days after the end of one of the menstrual discharges, found in the womb an egg, of the biggness of a black cherry: he asked the husband carefully, whether he had lain with his wife since the time of the menses; and was informed that he had. This egg was evidently the produce of that impregnation; and tho', at the utmost, it could be no more than four days old, the fœtus was plainly distinguishable in it, on an accurate inspection; and the head in some sort found: the rest of the body seemed an unformed mass of flesh. In such another case, where there was reason to believe the embryo about fifteen days old, the eyes, nose, ears, and mouth, were easily distinguishable in the head; and the body was so far fashioned, as to be easily known by its shape, and the rudiments of legs and arms appeared very plainly from it. The bones, as they are afterwards to become, are at these young periods mere gristles, and harden by degrees afterwards; but they soon acquire that degree of firmness, that the flesh may be taken off and they preserved as skeletons.

At about three weeks from the time of the conception, the fœtus has its cartilages for bones so perfect and so firm, that with due care in the management of so tender an object, the flesh may be separated, and a skeleton preserved of this small size. The head is very large at this period, in proportion to the body; but what is afterwards to become the skull, is only a membrane inflated with wind. The arms and hands are seen distinctly, and even all the fingers are formed. The number of the ribs may be easily counted, and the toes are as distinct as the fingers; but they are all so minute and tender, that a very nice hand, and very great art are necessary for the displaying them. After another week, that is, when the fœtus is a month old, the bones are so well formed, that the whole figure preserves its form, and is able to support itself. The jaw bones appear; the clavicles are formed; and all the ribs are very fair and distinct, except the first and last; and these two, even after another month, do not acquire the consistence of bones. At this period of one month, the joints of the arms, and those of the legs, are all very distinctly seen.

On examining a fœtus at two weeks beyond this period, that is, at six weeks from the time of conception, the inferior jaw bone has in it somewhat very remarkable; for it is plainly seen to be composed of six little bones; whereas, in the younger periods this is not observable; and when the child is born they are all joined together, and make but one bone.

These are the proportions of growth in fœtus's, which have continued regularly growing to the time of the death of the parent, and have been taken out by dissection afterwards: much less is to be judged from abortions, where the regular process of nature in the growth and formation of the fœtus is perverted, and the child has, perhaps, been dead some months before it is excluded, or has been sickly, and therefore not capable of taking nourishment, and growing as it should have done. For these reasons it not unfrequently happens, that an abortive fœtus of four months is not larger than one of these regular fœtus's of six or eight weeks; nor the parts any thing more advanced in their state and solidity, or if at all, but very imperfectly and irregularly.

Mr. Dennys has added some observations on this system of Kerkring; he agrees that these eggs, in which the rudiments of the fœtus are first to be discerned, are generated in the testicles of the female, and made to descend thence by the spiritous effect of the male-semen, making its way thither thro' the tubes; and adds, that they are of very different forms and sizes in different women. The same woman often has, in her testicles, eggs of very different sizes; and as to the proportion in size, between different animals, no regard seems paid in it to their bulk, since not only those of a cow, are much smaller than those of a woman, but those of a duck, or a hen, are vastly larger than either. The first beginnings of things do not always bear a proportion to their state and increase, in the animal or vegetable world: beans are a much larger seed than that of the apple or pear, tho' the latter raises a large tree, while the former only furnishes a small plant. The reason why the eggs of fowls are proportionably larger than those of the human species, or of quadrupeds, is, that they are to contain not only the young animal, but also the food for it to live on in the first part of its life. *Dennys*, in *Kerkring*, de Ovo.

Monsieur Gaulois observes, that the vesicles or eggs, in all sorts of females, are to be observed in three sorts of state or condition: First, while they are fastened to the place where nature has lodged them, as in a repository. Secondly, when they are loosened from the place. And Thirdly, when they inclose the embryo.

In the first of these states, they are common to all females in the animal world; and authors of long standing have observed, that there were in all the female animals, vesicles fastened to certain parts of their bodies. It is also certain, that after conception, that which incloses the fœtus is very like an egg; but this is no new doctrine neither, for even Hippocrates and Aristotle have advanced it: Harvey also, of later times, has treated very much at large on this subject. The whole matter, in the doctrine of Kerkring that is new, and that deserves a further enquiry is, whether these vesicles, which were always known to be fastened to the bodies of females, are at all loosened from them; and whether that kind of egg, wherein the embryo is found, be, or be not one of these vesicles loosened?

The system of Kerkring is founded on the answering this question in the affirmative; but those who are of the contrary opinion, who are not a few, think, that the bladder resembling an egg, in which the fœtus is formed, comes not from elsewhere, but is formed in the place of the conception; and Harvey pretends to explain in what manner it is formed there; and they all agree, that the vesicles, called eggs in females, are so fastened that they never can be removed; and even if they were, that there is no passage large enough for them to descend by from the place of their formation into the womb. Some pretend also, that if these are eggs then men have eggs also; for that the vesicles found in clusters at the sides of the *vasa deferentia*, which anatomists from their figure compare to a cluster of grapes, are truly and exactly of the same kind with those vesicles called eggs in females. See Eggs.

Ova, among the antients, a kind of verses, wherein the verses were reduced to the form of an egg. *Hofm.* in voc.

OVAL-*leaf*, among botanists. See Leaf.

Foramen OVALE. See Foramen *Ovale*.

OVARY, *ovarium* (*Cycl.*)—Ovarium of fishes. All fish have *ovaria*, but they, as well as the eggs they contain, differ greatly in the different kinds, in number, situation, figure, and structure. In the cetaceous, the cartilaginous, and most of the other kinds of fish, the *ovarium* is double, or there are two *ovaria*; but in some fish, as in the *osmarus*, the *perca fluviatilis* of Bellonius, and perhaps in some others it is single. As to its situation, it generally occupies the whole length of the abdomen, as in most of the spinose fishes; and in the petromyzum and accipenser. In many of the cartilaginous fishes it occupies only the upper part of the abdomen; and finally, in the cetaceous fishes it is placed at the corner of the uterus. As to its figure, it is generally oblong and compressed, as is seen in most of the spinose kinds: in those fish which have it single, it is oblong and cylindric, and in the cetaceous fishes it is round.

The eggs themselves are also very different in number and structure. In regard to number, they are in some fishes very few, as in the cetaceous kinds. In the cartilaginous kinds they are somewhat more numerous, amounting to fifty or a hundred; and in other kinds of fish they are so numerous, as to be beyond account.

In regard to their size and structure, they also differ considerably: in some fish they are large, and resemble a hen's egg in their contents; having a white, and yelk, and cicatricula,

tricula, all diſtinct in them, as in the cartilaginous fiſhes of many kinds. In others, as in the cetaceous kinds, they are very ſmall and ſimple, and have no diſtinct appearance either of white, yolk, or of the cicatricula. Hence it is evident, that the fœtus of cetaceous fiſhes, while included in the egg, receives its nouriſhment from the womb itſelf; but in the others, as the cartilaginous, and other fiſh, the white of the egg ſerves as nouriſhment to the fœtus while it remains in it. Finally, in the generality of other fiſhes, the eggs are very ſmall, and probably do contain a white, and yolk, tho' their ſize makes it not eaſy to ſee their parts diſtinctly. All the ſpinoſe fiſhes have theſe ſmall ſorts of eggs, and among the cartilaginous ones, the accipenſer and petromyzum. It has been ſuppoſed by ſome, that the eggs of theſe fiſhes were ſimple bodies, and only anſwered to what Harvey, and other authors on theſe ſubjects call the *cicatricula*; but this cannot be the caſe, for if ſo, the young fiſh muſt periſh; for the ſemen of the male fiſh is only ſcattered over the eggs while they lie in the water, and ſerves only to the rendring them prolific. The figures of all the eggs of fiſhes, ſo far as is yet known, is round. *Artedi*, Ichthyology.

OVATED-*leaf*, among botaniſts. See LEAF.

OUCH, in our old writers, a collar of gold, or ſuch like ornament, worn by women about their necks. Stat. 24 Hen. VIII. c. 13 *Blount*, *Cowel.*

OVEN, or *Aſſaying* OVEN, in metallurgy, is the particular ſort of furnace, uſed by the aſſayers in their operations on metals.

It is moſt conveniently conſtructed in the following manner:

Make with iron plates a hollow quadrangular priſm, eleven inches broad, and nine inches high, ending at top in a hollow quadrangular pyramid of ſeven inches in height; this priſm muſt be cloſed at bottom with ſuch another iron plate, which ſerves as a bottom to it. Near the bottom make a door three inches high, and five inches broad, to lead to the aſh-hole. Above this door, and at the height of ſix inches from the baſis, make another door of the figure of the ſegment of a circle, four inches broad at its baſis, and three inches and a half high in the middle; then faſten three iron plates on the forepart of this furnace; let the firſt of them, which muſt be eleven inches long, and half an inch high, be placed with its lower edge againſt the bottom of the furnace, and faſtened there with three or four rivets in ſuch a manner, that there may be, between the upper edge of the ſaid plate, and the ſide of the furnace, a groove ſo wide, that the ſliders of the lower door may be put into it, and freely move backward and forward therein: theſe muſt be made of a thicker iron plate.

The ſecond iron plate eleven inches long, and three inches high, muſt be placed perfectly parallel to the foregoing plate; and in the ſpace between the two doors in ſuch a manner, that both the upper and lower edge of it may, with the ſide of the furnace, form a hollow groove: one of theſe grooves which looks downward, ſerves to receive the upper edges of the ſliders that ſhut the lower door; and the other that looks upward, is to receive the inferior edges of the ſliders of the door above.

The third plate, which is to be of the ſame dimenſions with the firſt, muſt be riveted cloſe above the upper door, in ſuch a manner, that it may form a groove looking downward, and contiguous to the upper edge of the upper door. In order to ſhut both doors, you muſt adapt to each of them two ſliders made of iron plates, that may move within the above-mentioned grooves; but the two ſliders belonging to the upper door, muſt have each a hole near the top; that is, one a ſmall hole a fifth of an inch broad, and an inch and a half long; and the other a ſemicircular aperture, one inch high, and two inches broad: beſides this, let each ſlider have a handle, that it may be laid hold of when it is to be moved.

Beſide theſe, let five round holes, each of an inch in diameter, be bored in the furnace; two of theſe muſt be made in the fore part of the furnace, two in the back part of it, but all at the height of five inches from the bottom, and three inches and a half diſtant from each ſide of the furnace: and, finally, a fifth hole muſt be made at the height of one inch above the upper edge of the upper door. The inſide of the furnace muſt be lined throughout with iron hooks, ſtanding out about half an inch, and placed at about three inches diſtance from one another, to hold on, and faſten the matter of the lute, with which the whole inner ſurface of the furnace is to be coated.

Let an iron moveable hollow quadrangular pyramid, of three inches in height, be next adapted to the upper aperture of the furnace; this muſt be ſeven inches broad at the baſis, and end upwards in a hollow tube three inches in diameter, two inches high, and nearly cylindrical, but a little convergent at the top: this prominent tube ſerves to ſupport a funnel, or flue, which muſt be nearly cylindrical, hollow, and two foot high, and made of iron plates. This, when a very ſtrong fire is required, muſt be put perpendicularly upon the ſhorter tube, in ſuch a manner, that it enters cloſely and evenly into it an inch and a half, or two inches deep; and may be taken off at pleaſure when the fire is not required to be ſo very violent. This pyramidal cover muſt, however, have beſide, two handles fitted to it, that it may conveniently alſo be taken off or put on at pleaſure; and that this when put on the aperture of the furnace may not be ſubject to be eaſily thrown down, let an iron plate be riveted to the right and left upper edge of the furnace, and be turned down toward the inſide, ſo as to make a furrow open before and behind, into which the lateral edges of this cover may enter, and be faſtened, and at pleaſure moved backward and forward when it is to be put on or removed.

Laſtly, let a ſquare ledge, made of a thick iron plate, be faſtened on the top of the upper edge of the lower door, which will conveniently ſupport the grate and the lute; but this muſt be made of two pieces, that it may eaſily be introduced into the cavity of the furnace; and thus will you have an *aſſay oven* compleat, and ready for a great variety of operations.

When this is to be uſed, that the fire may be the better confined, and the iron not be deſtroyed by growing red-hot, the whole inſide of the furnace muſt be covered over with lute, a finger, or a finger and a half thick. The matter for the making the aſſaying metals, &c. or a mixture of clay with ſand, powder of calcined flints, or broken crucibles, either mixed with water, or with blood diluted with water, will ſerve very well for this purpoſe: but the moſt ready of all lutes, and at the ſame time one of the beſt in the world, is the coarſe earth called Windſor loam: this muſt be mixed up with water pretty ſtiff, and preſſed on the inſide of the furnace, firſt wetted alſo with water; and when this lute begins to dry, it muſt be beat down cloſe to the ſides with a wooden mallet; and then the unevenneſſes and cracks, filled up with clay ſomewhat moiſter, ſo as to be made ſmooth and even with a trowel, and then left to dry gently; and if any cracks happen, they muſt again be filled up. If any pieces of this lute are broken off by the fire, let it be quite cold, and wet it after the operation is over, and the edges of the old lute and freſh clay will unite very well, and fill up the holes. If the crack is but ſmall you may uſe the furnace again immediately, even before the freſh clay is dry.

This is the method of coating the *aſſay furnace* or *oven*; but before this is done there muſt be put within the furnace ſmall iron bars, equal in length to the diameter of the oven; theſe muſt be priſmatical in ſhape, quadrangular, and half an inch thick: their extremities will be ſupported by the ledge before deſcribed within the oven; and they muſt be placed at three quarters of an inch diſtance from one another. Theſe muſt alſo be ſo placed, that their flat ſides may be oblique with regard to the tranſverſe ſection of the furnace, and that the two oppoſite angles may look one upwards and the other downwards. The bars being thus not laid flat, but edgeways, you hinder the aſhes of the fuel of the fire from being detained too long between the interſtices of the bars, and from making any obſtruction that would oppoſe the free draught of the air. After the placing theſe, the furnace being coated over with lute, and dried by a gentle heat, is fit for uſe.

When an operation is to be performed in this, two iron bars of an inch in thickneſs, and ſomewhat more than the diameter of the furnace in length, muſt be put thro' the four holes before deſcribed, ſtanding oppoſite to one another; and the ends of the bars muſt jut out a little beyond the edges of the holes on each ſide; theſe ſerve to ſupport the muffle with its bottom, in which the coppel or teſt, with the matter to be worked on is to be placed: theſe are then to be introduced thro' the upper aperture of the furnace, and ſet on theſe bars in ſuch a manner, that the open foreſide of the muffle be contiguous to the inward border of the upper door. The fuel is to be introduced thro' the top of the furnace, and the cover on this account muſt be moveable, and not too heavy. The beſt fuel is charcoal made of hard wood, and broken into pieces of an inch big, that the muffle may be covered regularly over ſome inches high; large pieces of coal are to be avoided at this time, becauſe they cannot fall into the narrow interſtices between the ſides of the muffle and thoſe of the furnace; and cannot of courſe ſurround every way this circumference of the muffle; for which reaſon if ſuch were uſed, there muſt be ſome places void of fuel, and the fire, conſequently, either not ſtrong enough, or unequal: and if, on the other hand, the pieces of coal were too ſmall, they would fall immediately thro' the interſtices of the grate into the aſh hole, and the tendereſt particles of them turn too ſoon into aſhes, and increaſe the heap of aſhes, and obſtruct the free draught of the air.

Scotch coal, or Kennel coal, but not Newcaſtle or ſea coal, broken into ſmall pieces, may be mixed with an equal quantity of charcoal; or if any ores require long roaſting, the fire may be firſt kindled with Scotch coal alone, but the operation muſt be finiſhed with charcoal alone. *Cramer's* Art of Aſſ. p. 75. ſeq.

OVER (*Cycl.*) — OVER-*blow*, in the ſea language. They ſay it *over-blows* when the wind blows ſo very hard that the ſhip can bear no top ſails.

OVER-

OVER-*done*, in the manege, in French, *outré*. A horse is said to be *over-done*, or *outré*, when his wind and strength are broke and exhausted with fatigue.

OVER-*flowing of lands*. The farmers of England having long observed how great an advantage it was to meadow and pasture land, to be sometimes *over-flowed* by the sudden rise of brooks, rivers, or the like, which brings the soil of the uplands upon them, and makes them need no other mending or manuring, tho' constantly mowed, have found an artificial method of working the same effect, and by it producing the same good effect in many of their grounds without any ill one. The benefit of the natural *over-flowings* of meadow lands, which lie in the way of floods, is in some sort taken off, by their being subject also to these inundations at improper times; and when a winter flood has caused a fine crop of grass, a summer flood sometimes comes and destroys it all before the hay-making season.

There are some lands so advantageously situated, that with the assistance of art they may be laid under water or left dry, at the pleasure of the farmer. These are the most valuable of all grass lands, and it is upon these that the farmer practises his artificial *over-flowings*; improving them in winter by letting in the floods to have their soil for manure upon them, and keeping them dry in summer when the grass is long.

The artificial *over-flowing* of lands is commonly effected by directing the streams of rivers, brooks, springs, or land floods, or some part of them, out of their proper channel; but where the streams lie so low as to be incapable of *over-flowing* the lands, they are made use of to turn such engines as may raise a quantity of water sufficient to do it. The best and cheapest engine for effecting this, is that called the Persian wheel; which may be made of any size, according to the height the water is to be raised to, and the strength of the stream by which it is turned. This wheel is placed so, that its bottom only is immersed in the stream; and there are open boxes at its cogs; these are all filled one after another with water, which is raised with them to the upper part of the wheel's circuit, and then naturally empties itself into a trough which carries it to the land.

Where there are not streams to turn this wheel, the farmers have recourse to pumps, and other engines, moved by wind. Lands that lie near brooks give more frequent opportunities for these practices, than those which are near rivers; the brooks having greater falls, and the rivers running more slow and level: but when it can be effected by the water of large rivers, the land is yet more enriched by it, these waters being more fruitful than the others.

When the water is, by this engine, thrown into the trough, it is to be conducted by it to the highest part of the land; and when that is sufficiently flooded, the water is to be let into a large but not deep trench, several small ones running out of which to all parts of the land, may convey it every where, and every part may be enriched by it. It is always proper to contrive this matter so, that the *overflowing* may be often repeated, and the water quickly carried off; for when it is suffered to lie long upon the land in winter, it is apt to breed rushes and other coarse plants in the ground.

Some farmers graze their lands till Christmas, and some longer; but as soon as fed bare, from Allhallows till spring, that the grass is not too high, is the properest time of *overflowing*, except that it prove a dry time in April or May. If this happen, *overflowing* the lands at this time will be of singular advantage; for the grass will grow three times as fast after it, in hot weather, as it would in cold. Land-floods are the best to *overflow* with in winter, and warm fattening springs in summer; only it must be observed, that the water of one operation is dried in before any more is let on. It is always best also to do it at night, that the moisture may be soaked into the ground before the heat of the day; for otherwise the land is often burnt. The washings of towns and of public highways is of great improvement to lands, as is also the washings of lands where sheep feed.

All waters are not proper for this purpose of *overflowing* of lands to enrich them, the waters of coal mines and other places where there is any sulphureous mineral mixed among them, being apt to destroy and kill the grass where-ever they come. These waters are easily known from the healthful spring, by their leaving a reddish mud or sediment behind them where-ever they have passed; but it is possible, that even these may have their use when properly applied. They seem to contain a vast quantity of salt of some kind, and we know that urine, dung, and many other things, that are most fit of all others to enrich land, will burn up and destroy plants, if improperly laid on in large quantities: the case may be the same in these, and very probably these waters abounding in salt would do great good if they were properly blended with common water, and let in upon the lands with floods of sweet water. The farmers have gone so far towards the proving the truth of this, that they have found some of these springs, when more distant from their source, not only more innocent than before, but beneficial.

Cold clay lands, and other strong lands that lie flat, will only be improved by *overflowing* them with land floods, and that only in summer, when the season is very dry. These lands will not bear water in such quantity at any other time, because it will not soak into them easily; and it is for the contrary reason, that the light and spungy lands are always most improved by *overflowing*. *Mortimer*'s Husbandry.

OVER-*grown*, in the sea language. When the waves of the sea grow high, the sailors call it *rough sea*; but when the surges and billows grow vastly high, then it is an *overgrown sea*.

OVER-*hale*, in the sea language. A rope is said to be *overhaled*, when drawn too stiff, or haled the contrary way.

OVER-*hale the runner*, in the sea language. See RUNNER.

OVER-*hale the sheet*, in the sea language. See SHEET.

OVER-*ride*, in the manege, the same with *over-done*. See the article OVER-*done*, supra

OVER *set*, or *overthrow*, in the sea language. A ship is said to *over-set* when her keel turns upwards; which misfortune happens either by bearing too much sail, or by grounding her, so that she falls upon one side.

OVER-*worked*, in the manege, is the same with *over-done*. It is called in French, *estrapasser*. See OVER-*done* and ESTRAPASSER.

OVER-*laying of children* may be prevented by a machine called *arcuccio*. See ARCUCCIO.

OVIEDA, in botany, the name given by Linnæus to a genus of plants, called by Plumier *valdia*. The characters of which are these: the perianthium is a short and broad one-leaved cup, lightly divided into five erect and pointed segments, and remaining after the flower is fallen. The flower consists of one petal, and is of the labiated kind. The tube is extremely long and slender, and stands upon the germen of the pistil. It is somewhat thicker at the top than at the base, and the upper lip is hollow and emarginated; the lower is divided into three segments. The stamina are four filaments longer than the flower. The antheræ are roundish. The germen of the pistil is globose, and stands between the cup and the flower. The style is capillary, and of the length of the stamina; and the stigma is bifid and acute. The fruit is a globose berry, placed in the cup, which grows larger to receive it, and is of a campaniform shape. The seeds are oval, and are two in number. *Linnæi* Gen. Plant. p. 295. *Plumier*, Gen 24.

OVILE, among the Romans, a name given to the enclosures in which the comitia met to create magistrates. See the article COMITIA, *Cycl.*

OVIPAROUS (*Cycl.*)—The distinction between *oviparous* and viviparous creatures, seems, in the insect world, to be much less fixed and determinate than is supposed. It is evident, that some flies, which are naturally *oviparous*, if they are kept from the finding a proper nidus for their eggs, be it meat, or any thing else, will retain them so long beyond their due time of exclusion, that they will hatch into worms in the body of the parent, and be afterwards deposited alive on flesh, or in the manner of the young of the viviparous insects. Bartholine gives an account in his Medical observations, of a hen, which, instead of eggs, brought forth no less than five living chickens; but she died of it

This story of Bartholine is countenanced in a great measure by a thing which happened in this kingdom; where, in the county of Norfolk, some years after his publishing this history, there was a hen, which, tho' big with eggs, could not lay, but after a time died; and people being curious to open her afterwards, there was found in the ovarium, a chicken disclosed from the shell, and perfectly formed in all its parts; and probably had this been excluded in this state, more would have followed, after being hatched in the same unnatural manner. We have in some authors instances given of the same accident in the serpent kind, which puzzle the distinction between the *oviparous* and viviparous kinds.

OVIS, the *sheep*. The character of this genus of animals, given by naturalists, is, that the covering is wool, not hair; the mouth proportionably smaller than in the ox kind; the horns crooked, wrinkled, and often spiral, and the papillæ only two.

The wool of these animals is only a congeries of very long and slender hairs, oddly twisted and contorted, and variously interwoven with one another. This is a cloathing peculiar to the sheep kind, so far as is yet known, no other animal having been seen to possess it: it is not, however, the cloathing of all the species of sheep, some of the distant nations having short hair, like that of the goat.

We at present know five species of this animal: 1. The common *sheep* of our own pastures. 2. The *ovis laticauda*, famous for the enormous size and breadth of its tail, which often weighs thirty pounds. See the article PLATYCERCOS. 3. The *ovis strepsichoros*. See STREPSICHOROS. 4. The *ovis Africana*, or African *sheep*, which instead of the wool of the *ovis*, has short hair like that of the goat; we have these often brought into England, and they seem no way different from ours but in their covering. And 5, the *ovis Guineensis*, commonly called the *Angola sheep*. This is of the size of our *sheep*, but the hinder part of its head is more prominent, and its ears hang down. Their scrotum is very large, and their penis placed in the middle of the belly, the horns small, and bending down to the eyes; and the neck adorned with a large mane.

mane. The hair of the reft of the body is fhort, and they have a dewlap under the throat like our bulls. *Ray's* Syn. Quad. p 73.

To thefe are ufually added the *pacos* and *mufmon*; the firft of which properly belong to the camel clafs, not the *fheep*, and the latter an animal fufpected not to be found any where at this time.

In the Linnæan fyftem of zoology, the *fheep* makes a diftinct genus of animals, of the order of the *pecora*. The characters by which the creatures of this genus are diftinguifhed from the reft of that order, are thefe: their horns are hollow, bent backward, wreathed and crooked, and fcabrous, not fmooth on their outfide. *Linnæi* Syftem. Nat. p. 43.

OUMIEN, a name given by the Chinefe to a peculiar fort of porcelain, of which they are very fond. It is black, ornamented with gold. They fometimes alfo call the blue and gold, which is made in the fame manner, by the fame name. They colour it with three parts of the azure, and feven parts oil of ftone, and lay on the gold afterwards. If they would have it bluifh, they add lefs of the azure, and fome cerufs white. Obferv. de l'Afie.

OUNCE (*Cycl.*) — The *ounce averdupois* weight, is about $37\frac{1}{2}$ grains *troy*. See POUND.

OUNCE is alfo the Englifh name of the lynx, or *lupus cervarius*, a very fierce beaft of prey. See LYNX.

OURISSIA, in zoology, a name by which Clufius and fome other authors have called the *humming-bird*, or *guainumbi*. *Cluf* Exot. l. 5. c. 7. See the article GUAINUMBI.

OUROLOGY, in medicine, a name given by authors to a treatife or difcourfe on the fubject of urine. The chemifts have given us treatifes on the analyfis of urine, and the preparations of it, fuch as the phofphorus, &c. under the name of *ourologies*: and medical writers have, under the fame name, given us treatifes on the prognoftics from the urine, and its various appearance in different difeafes.

The firft ftep towards judging by the urine, is to fix fomething as its ftandard in a healthy ftate, all the deviations from which, in whatever refpect, are to be judged fignals of diftempers or diftempered habits. This ftandard is beft taken from the urine of a perfon in health, of between thirty and forty years old, and it is of a citron colour and moderate confiftence, of a due and fomewhat ftrong fmell, and made in a confiderable quantity. This, when it has ftood a proper time, is alfo to depofit a natural fediment. By being well acquainted with all the ftages and changes of this, the difeafed urine will be eafily judged of by their feveral peculiarities in difference from it. Phil. Tranf. N°. 100.

It is faid by fome, that people often die with good and healthful urine; but this is only faid by thofe who are not fkilful in urine: for it is as impoffible for the urine to be healthful at the approach of death in difeafes, as for the blood to be fo.

The time of infpecting the urine, and the time that the urine is made that is to be infpected, are alfo circumftances of great confequence. The urine by which the beft judgment is to be formed, is that made after the firft fleep in the night; and the time of judging of this is not immediately when it is made, but about two hours after, when it has had time to fettle. It muft in the mean time be fet to fettle in a moderate air, neither too cold nor too hot. The firft hinders the fettling, and the latter rarifies the colour; and if very great, it caufes an ebullition, which deftroys what fhould fwim upon the furface of the urine. The urine muft not be judged of in the fun, nor by candle-light; for either of thefe lights will give falfe colours: but the proper place is, when there is a moderate, not glaring light; and when it is firft received, it muft be held very ftill and fteady; afterwards it will be proper to fhake it, to fee the whole that fwims in it, and will feparate from it. *Eygel.* de Urinis.

The colour of the urine is the moft precarious of all its appearances, and to be judged of with the greateft caution. What is taken to be the mark of a difeafe in this cafe, is often only the effect of medicines or the food: rhubarb or faffron will make the urine yellow, and a common fallad will make it greenifh; but thefe tinctures go off after a few hours from the time of taking the things which occafion them. People who live in a hot air, and thofe who ufe violent exercife, ufually make more high coloured urine than others. The fubftance, the quantity, the qualities, and the contents of the urine, will always difcover to the attentive view the nature, caufe, and fymptoms of the perfon who made it. What is moft to be obferved as to the fubftance of the urine is, whether it be thick or thin, clear or turbid, oily or not oily. The copioufnefs of it is only to be judged of by comparifon of the quantity voided within the twenty-four hours by the patient, with that he ufed to void in health, or that quantity which at a medium a man in health does ufually void. Among the qualities of the urine, the principal is the fmell. This is affected not only by difeafes, but by medicines taken for them. The urine is on many occafions rendered fœtid; and there are fome things which communicate an agreeable fmell to it, fuch as turpentine and many of the diftilled oils. Among the things which render the urine fœtid, the principal are ulcers and purulent matter. The tafte of the urine alfo declares its qualities. It is naturally of a faltifh and fulphurous tafte, but this goes off, and a fweetnefs or infipidity is obferved in it. The principal colours of the urine in its various ftates, as inflamed by difeafes, are white, yellow, reddifh, and black; to one or two of thefe, differing in degree or to mixtures of two or more of them, in different proportions, may be referred the other lefs common colours of pale citron, high-red, green and blue, which laft two, in any perfect degree, are very uncommon. The moft dangerous of all urines are the blue and the black, particularly the laft: the antients, however, judged too feverely of it. Galen fays, he never knew any one recover who made black urine; but we meet with fome inftances of children efcaping after this fymptom.

The contents of the urine are of three kinds: the fediment or matter fubfiding to the bottom; the matter hanging in the middle; and the matter fwimming at the top. Thefe differ according to their degrees of weight, and in all thefe the phyfician is to obferve, the fubftance, colour, uniformity and likenefs. For example: the beft fediment is that which is moderate in fubftance and quantity, white, uniform, and alike both for matter and time. We are not to expect a fediment in the urine in all difeafes, and in fome a thinner, in others a thicker fediment, is the beft fymptom. Among all the appearances of the middle and top of the urine, the worft is that of a fort of clouds forming themfelves in the urine, and rifing to the top entirely. Thefe are the figns of light-headednefs, and often of death itfelf.

Befides thefe, which are the general contents of urine, there are particular ones; fuch as mealy matter, fcales, coagulated blood, purulent matter, afhes, flime, pieces of feeming flefhy matter, fmall hairs, woolly filaments, flying duft, tough ftuff adhering to the fides of the veffel, and refembling the webs of fpiders, bladders, froth, fat or cream-like fubftances, and finally fandy or ftony matter. This laft is the moft frequent of all, and is of two kinds; the one found in the body, the other only feparated from the urine after it is difcharged. It is of great confequence to know thefe, as they give great light into the nature of nephritic complaints. The fandy matter generated in the body always precipitates itfelf to the bottom in the urine, as foon as it is made, and remains loofe in it; but the other only feparates from it in the pot, and adheres to the fides of it in form of a fort of cruft. It has been fuppofed by many, that prefages of the ftone may be made from thefe feparations from the urine, but there is no certainty in it; only this, that thofe who have been ufed to void grains of fand, if they fuddenly leave it off, and from that time begin to make a whitifh and thin urine, they then may be fufpected to have a ftone breeding within them.

The nature of the fand voided at times by people afflicted with the ftone, may ferve as a guide to judge of the nature of the difeafe. When it is hard and red, the ftone is likely to be fituated in the bladder; if hard and white, the kidneys are likely to be the feat of the diforder. We have inftances of very particular matters voided by urine, befide thefe: fome wholly erroneous; others certain, tho' very ftrange. Plempius gives an account of a woman who voided a yellow fatty matter with her urine for feveral months after the going off of a quartan ague, and tho' fhe difcharged great quantities of this, was not at all the better for it. Phil. Tranf. N°. 100.

OUT, OUTSIDE, or WITHOUT, in the manege, is the contrary of *in*, *infide*, *inner*, &c. See IN, INNER, &c.

OUTIN, in zoology, a name by which fome call the fifh known among authors by the name of *oxyrynchus*. *Willughby's* Hift. Pifc. p. 187. See the article OXYRYNCHUS.

OUTLICKER, or OUTLIGGER, in a fhip, a fmall piece of timber, three or four yards long, as occafion ferves, made faft to the top of the poop, and ftanding right out a-ftern: at the outmoft end of it is a hole, into which the ftanding part of the fheet is received, and made faft through the block of the fheet; and then again received through another block, which is feized to this *outlicker*, hard by the end of it. This is feldom ufed in men of war, or in great fhips; and whenever it is made ufe of, it is becaufe the mizen maft is placed fo far aft, that there is not room enough within board to hale the fheet flat.

Outligger feems the true orthography of the word, which appears to be derived from the Dutch *uitlegger*, q. d. *outlier*.

OUTNESS, is ufed by fome for that relation of things by which one appears out of, or at a diftance from another.

Dr. Berkeley, in his effay on vifion, makes ufe of the word *outnefs*; and obferves, that we form no notion of *outnefs* from the fenfe of feeing merely, but only from motion.

OVUM (*Cycl.*) — OVUM-*Anguinum*, a name given by many authors to a foffil, fuppofed by the vulgar to be the petrified egg of a ferpent, but being really like the brontiæ and ombriæ, fpecies of the *echinites*. See ECHINITES.

OVUM-*polypi*, in natural hiftory, a name given by fome of the earlier writers, to the papyraceous, or thin-fhelled nautilus. The refemblance of the body and arms of the fifh which inhabits this fhell, with thofe of the fea-polypus, gave occafion to their fuppofing this creature the fame animal, not yet got out of the egg. The fhell of this fpecies being very thin,

and looking like an egg-shell, gave farther countenance to this error in less knowing ages.

Ovum *rumphii*, in natural history, the name of a species of *porcelane shell*, of the oblong kind, called an *egg*, from its shape, by that author. See Porcellana.

OUZELL, or *Brook* Ouzell, in zoology, an English name for the *rollus aquaticus*, more usually called the *water rail*. See the article Rollus.

Ouzell, or *Ring* Ouzell, an English name for a bird of the *merula* or *blackbird* kind, remarkable for a white ring about its neck, and thence called by authors *merula torquata*; it is more commonly called in English, the *ring amzell*. *Ray's* Ornithology, p. 144. See Amzell.

OUZEL, or *Water* Ouzel, the English name of the *merula aquatica*. See Merula.

OWL, in zoology. See the article Bubo.

Churn Owl. See Caprimulgus.

Horn Owl. See Horn.

Owl *fish*, or *sea* Owl, in ichthyography, an English name for the *lumpus*, more frequently called the *lump-fish*; and by the Scotch the *cock-paddle*. *Willughby's* Hist. Pisc. p. 208. See the article Lumpus.

Owl *pigeon*, the name of a particular species of *pigeon*, called by Moore the *columba bubo nominata*. It is a small and short-bodied *pigeon*. It has a short round head, and has a series of feathers that separate and open two ways upon the breast: but its most remarkable character is its beak, the upper chop of which is bent, and hooked over like an owl's: this is the occasion of its name. It is of various colours, as white, blue, or black, but is always of only one colour, never pied. *Moore's* Columbarium, p. 54.

OX, *bos*, in zoology. See the article Bos.

The *ox* is a very serviceable animal, in many respects; but his nature depends wholly on that of the bull and cow, from which he is bred. Derbyshire and Lancashire are said to have the best *oxen* in England. Wales, and the island of Anglesea, afford a kind that are very valuable to the farmers, as they will fatten upon middling land; and the Scotch *oxen* are yet hardier than these. The long-legged short-horned cow, of the Dutch breed, is the best for milk; but then this kind needs to be very carefully kept. This sort of cow will often yield two gallons of milk at a time.

When these creatures are intended to breed, the better the land is the larger sort of beasts are to be chosen, and the greater will be the profit. But of whatever sort the breed is, the bull should always be of the same country with the cow, otherwise it never succeeds so well. The bull should be chosen of a sharp quick countenance, his forehead broad and curled, his eyes black and large, his horns long, his neck fleshy, his belly long and large, and his hair smooth and like velvet; his breast should be large, his back strait and flat, his buttocks square, his thighs round, his legs strait, and his joints short. This sort of bull is the best for breed, and makes the best *oxen* for draught as well as for fattening.

The cow ought to have a broad forehead, black eyes, great clean horns, the neck long and thin, the belly large and deep, the thighs thick, the legs round, and the joints short; a white large and deep udder with four teats, and large feet. The size must be proportioned to the goodness of the land. The largest cows, in general, give the greatest quantity of milk; and it is always a good rule to take the cattle from a worse ground than that on which they are to be kept; for if from a better they are apt to degenerate. The best time of a cow's life for breeding of calves, is from three years old till twelve: the black cows are usually chosen to breed out of.

The largest *oxen* are to be chosen for work, and for feeding, but then it must be where there is land rich enough to maintain them. When they are to draw, care must be taken to match them well, both for height and strength; for if one be stronger than the other, the weakest will soon be destroyed. They must never be driven beyond their natural pace, for the beating them throws them into surfeits, and many other diseases. The time of putting *oxen* to work, is at three years old; they must be worked gently the first year, especially in hot weather, and fed with a large quantity of hay: this will enable them to bear their labour better than grass; and they should be always kept in a middle state, neither too fat nor too lean. They may be worked till they are ten or twelve year old, and then sold.

It is observed, that meat and fair treatment, succeed much better with this animal than blows. The best way to break a young one to the yoke, is to put him to it with an old tame *ox* of about his own height and strength. If he prove unruly after this, he must be kept hungry, and made to feed out of the driver's hand. *Oxen* are much more profitable to keep than horses, there being no loss in them; and an old wrought *ox* fattening as well as a young one, and being as good meat. Their keeping also is cheaper, for they eat no oats: their harness and their shoes also are considerably cheaper, and they are not so subject to diseases. They must always indeed have good grass and good hay, and they are not so serviceable as horses, when there is much working in carts, and where the ways are good; but for winter plowing, where the ground is heavy, an *ox* will do as much work as a horse. Every farmer who can keep two teams, would do wisely to have one of them of horses, and the other of *oxen*; it is much better to yoke them together by the necks and breasts, than by the horns as some do; and where a man keeps an *ox* team, he should raise two *oxen* and two cow calves every year to keep up his stock; for it is better for a farmer, in all necessary things, to be a seller than a buyer. Chalky land spoils the feet of *oxen* more than any other. *Mortimer's* Husbandry, p. 233.

Stealing Oxen, or creatures of the *ox* kind, old or young, whether bull, cow, *&c.* strictly so called, steer, bullock, heifer, or calf, is now felony without benefit of clergy; as is likewise killing any of these, with an intent to steal any part of their carcases. Stat. 15 & 16. Geo. II. c. 34. & Stat. 14. Geo. II. c. 6. See Cattle.

Diseases of Oxen. As scarce any creature is more useful to man than the *ox* kind, nothing is more worthy consideration than the nature and origin of their diseases, and the remedies for them. The same distemper that has of late years carried off such vast numbers of these cattle with us and elsewhere, has at other times raged in Italy. In the year 1710, and the succeeding one, there was a great mortality amongst the horned cattle there, and the occasion of it was evidently the unnatural season preceding. The whole autumn before had been wet, and at the time of the winter solstice there were continual cold winds, and small, but lasting rains. The spring that succeeded, was also cold and rainy, and the defect of heat and abundance of moisture, made a change in the whole face of nature: the medicinal springs had not their wonted effect; and the fruits of the earth could not appear at their proper seasons, nor in their due perfection. The grass was injured by this, and the ground rendered continually damp and unwholesome; and to this was evidently owing the malignant and contagious disease that raged among the cattle afterwards. It was supposed at that time with them, as of late with us and elsewhere, that the contagion was brought in among their *oxen* by strange cattle coming from infected places, but this proved to be an error; for if an *ox* was removed to ever so distant a pasture, he never escaped the better for it: the whole earth and its productions were vitiated throughout the country, and there was no safety in any part of it. *Michelotti* de Morbis Boum.

The use of this observation must be, the keeping the cattle in succeeding years out of the way of those things which occasion their sicknesses in such as these. If the autumn or winter be extremely cold and wet, remove the cattle out of the low grounds, and put them to feed in sandy dry soils on the high grounds; give them water from such places where the sun has most power, and it is less chilling cold than in others; and in cases of imminent danger, always mix some salt in it. If the bad weather continues, let them always have clean straw to lie on, and a dry covering; and in cases where the contagion is already begun, the fumigating the houses where they are kept with bay-leaves and eleutherian bark, is judged convenient. As to remedies, when they are once seized with the distemper, it is hard to understand what intention to prescribe in, and how to ascertain the doses; and as the late practice, in attempting to cure, has been of very little service, the cautions for the preserving and preventing the disease, ought to be redoubled, to prevent an almost incurable misfortune.

The diseases of *oxen* are much less frequent than those of the human species; but where-ever they appear, they usually become more violent after a time, and generally are very contagious. In Italy in the year 1711, there appeared a disease among the *oxen*, which carried off as great numbers as the late distemper among us has done. Some acrid and caustic salts in the blood, seem to have been one of the principal causes of this disease; as when the blood was let out at the ear of the dying cattle, and fell upon the ground, there were always found, as it dried up, certain concretions of salts sparkling like so many crystals.

In many of the creatures which were opened, after dying with this disease, the insides of the stomach and intestines were found covered with tubercles like the pustules of the small-pox: the common people supposed this the cause of the disease; but upon farther enquiry, it appeared only one of the effects of it; for such beasts as died very suddenly of this disease, when opened, had their intestines sound; so that these pustules on their surface appear to have been only a symptom of the disease in a very advanced stage. All medicines were found vain in this disease; and such of the creatures as recovered, had always pustules of this kind on their skin, which oozed out a bloody ichor.

From the whole it appears, that this disease was an acute fever in these creatures, of a malignant kind; and that the texture of the blood was always broke in it; and that its cause was to be attributed to various salts taken in from the air, or in eating or drinking. Many had called it a plague among the cattle, but it appeared rather what we understand by the name of a contagious pestilential fever, than an absolute plague; and a peculiarly humid season, joined with exhalations of mineral substances out of the earth, for some reason which we cannot comprehend, more frequent than usual

usual, brought it upon these creatures, whose noses being continually near the ground, gave these exhalations immediate entrance
The method of cure seems to consist in two intentions; the first of abating the fever; the second of restraining the acrimonious malignity of the salts.
Purges of all kinds are cautiously to be avoided; and bleeding in the beginning is always necessary, and must be more largely admitted in the more robust creatures. The common medicines given as febrifuges and cephalics, all do harm; the fumigations of diverse kinds, all are idle or mischievous; and most of these things intended as reliefs, tend plainly to the increasing the disease, as they add to the accelerated motion of the blood, and break its texture more than before. The most rational method of treatment is this:
As soon as a beast is seen to be affected, let him be separated from the rest and kept warm. When his mouth begins to be sore, let a clyster be given; and if this does not work, then a gentle emollient may be given by the mouth, made of lenitive electuary and cream of tartar, dissolved in a large quantity of water-gruel; this is the more necessary if the creature be fat: if a lean beast be seized, bleeding is the first thing to be done; after this, a seton must be made in the neck, and the parts about where the vein was opened should be scarified. If the fever does not abate on these methods, the creature should be blooded again: then, instead of the great quantities of watry liquors, which are usually given, the creature should have something strong, such as a mixture of wine with its liquor, and that in considerable quantity. When the fever abates, he is to be allowed but little drink for the three first days, and that should be a decoction of mallows with a mixture of lemon juice, or some other such acid. In cases where the seton does not discharge kindly, a blister must be applied over it. When by this means the creature begins to recover, elm leaves and olive leaves, are to be mixed with the hay it eats; the creature must be walked out a little, and its litter changed for fresh: this should be done every day, in cases where the creature is weak and poor.
For the preservation of cattle from the disease, nothing is so proper as the taking great care that they drink only clean and pure water, and that they eat only dry food till some hours after sun-rise: they must be carefully kept out of infected places, and their stables fumigated, by burning in them frankinsence, juniper berries, and the like ingredients; or by firing off small quantities of gunpowder at several times, or sprinkling vinegar and camphor on a red-hot iron. The creatures mouths should be washed at times with lemon juice, and their ears with vinegar or urine; and no hogs, sheep, or other animals should be suffered to feed among them. *Gazola* de Peste Boum.
These were the sentiments of Gazola on this fatal disease, which he had carefully attended to in all its stages Lancisi, however, dissents from this author in some particulars. He says, that the distemper was a true plague among the cattle; and observes, that this very plague among the *oxen*, was well known among the antients. It was first brought into Italy from Hungary, and infected the cattle by the breath, by the pores of the skin, or by any other passage that it found open. He prescribes for the preservation, the taking great care that they have perfectly good food and drink; and advises the washing their mouth and nostrils with a mixture of vinegar, garlick, sulphur, salt, and juniper berries; and both he and Gazola agree in advising the rubbing the creatures over with sweet oil. This author condemns all medicines, and even bleeding, but greatly recommends setons, cauteries, and blisters. He advises these to be used as soon as ever the creature is perceived to be sick, and that not only on the neck, but on the shoulders, the hips, and any other part. *Lancisi*, ap. Acta Eruditor. Ann 1715. p. 463.
Franciscus Fantasti published a treatise on the same subject, about the same time; and by his writings it appears, that the *oxen* were seized differently, and affected with different symptoms in different places, tho' the cause of the distemper was evidently the same in all.
Some of the cattle, he observed, voided great quantities of blood by the urinary passages. These usually died, and on opening them the blood was always found fluid, and the brain was often decayed, or full of a fœtid matter; and the marrow in their bones was found dried up and wasted, and all the humors were found evidently tending to a state of corruption.
This author rejects bleeding in all periods of the disease, as a practice that could be of no use in a case where the blood and humors had all lost their due state, and were tending to corruption. He commends scarification and cauteries; he also greatly recommends the trepaning the horns to the medullary part, and the making setons in the ears, on their necks, and in their breasts; the only internal medicine he prescribes, is a mixture of the theriaca diatessaron, two ounces; discordium, one ounce; powder of peruvian bark, two ounces. This dose is to be given every day for three successive days, dissolved in three pints of the juice of brook lime, water cress, and scurvy grass, with the addition of a pint of strong white wine. John Baptist Mazzini, wrote in another part of the world at the same time, on the same subject; with him we find, that the *oxen* which were seized with the disease, continually had a running of a mucous matter from their nose, and a weeping at the eyes; and that when the corners of these creature's eyes were washed with wine, in which sage leaves had been infused, there came out several clusters of small and slender worms twisted one among another, and forming little bundles of twenty and more. He observes also, that these creatures, when affected, usually carried their heads upward, not bending to the earth as usual. This author advises every thing to be done to promote perspiration: he prescribes contrayerva and angelica root, in white wine, in large doses once or twice a day warm, and recommends the fumigating their stalls with juniper and bay berries. The washing their mouths and nostrils with wine and sulphur, is also prescribed in his treatise: a decoction of rosemary, fennell, and sage, with white wine, vinegar, and salt, is also recommended as a drink to be often given; and he prescribes the holding their heads forcibly in a depending posture, that they may give opportunity to the saliva to run out, and the washing their mouth with vinegar and salt to cleanse it of the foulness. *Mazzini*, Litter. ad Vallisnier. de Peste Boum.

Ox-*eye*, in the sea language, a name given by the seamen to those dreadful storms that are sometimes met with on the coast of Guinea; for at first it appears in the form of an *ox's* eye, and not much bigger; but it descends with such celerity, that in a very little space of time, and often before they can prepare themselves for it, it seems to them to overspread the whole hemisphere; and at the same time forces the air with so much violence, that the ships are sometimes scattered several ways, some directly contrary, and sometimes are sunk down right.

Ox-*eye*, *certhia*, in ornithology. See Certhia.

Ox-*fly*, in natural history, a species of two-winged fly, bred from a fly-worm, hatched under the skin of oxen, from the egg of the parent fly lodged there.
The female of this fly makes a number of small wounds in the backs of horned cattle, and in each of these deposits an egg; which is afterwards hatched by the warmth of the creature's body. As soon as hatched, the young worm finds itself in a very convenient lodging, and in a way to be furnished with all the necessaries of life.
The places were they lie are easily discovered, as there is ever a tumor about them, like that on the foreheads of children from falls; within this, and under the thick skin of the creature, is the worm lodged. The country-people know very well that a worm is contained within each of these tumors, but they are something mistaken as to the fly it comes from; the gad-fly being the most busy about these creatures, and giving them most vexation, they naturally enough have supposed this the produce of the egg of that fly; but this is an erroneous opinion: Mr. Vallisnieri seems the first who understood the true state of the case, and he has given a very full and excellent account of it.
Every one of these tumors on the ox has within it a cavity proportioned to the size of the worm, and both the internal cavity, and the external tumor, always increase gradually as the inclosed worm grows larger. In the middle of May these tumors are seen of their full size, and are then an inch high, and an inch and a half broad at their base.
The greater number of these tumours are always found on cattle of about three years old. The number of tumors on the creature are uncertain, and are according to the number of eggs which have succeeded from the laying of the fly; sometimes only three or four, sometimes twenty or thirty, or more, are found on the same creature. They are not regularly placed, but are usually on the back about the spine, tho' sometimes on the legs and shoulders. Sometimes they stand very close to one another; sometimes they are more distinct and separate. It is observed also, that the oxen which feed on open plains are much less subject to them than those that are kept in the neighbourhood of woods.
At the time when the worm has obtained its full growth, and is about to leave the tumor, there is a perforation in it sufficiently plain to eyes accustomed to observations of this kind; nor is it indeed only at this time that this hole may be observed; it is distinguishable at all times, if properly sought after, and is evidently the hole made by the parent fly to introduce its egg, which has never closed, but, on the contrary, has opened more as the tumor increased, and the inclosed worm grew; but toward the end of the time that the worm is inclosed, it enlarges much more quickly than at any other period.
The hole is placed in various parts of the tumor, but very rarely on or near its top, more frequently near some part of its circumference. But these often, tho' near the circumference while the tumor is small, become situated at its top, when it is grown to its utmost size, from the irregular growth of its several parts. This hole is of very signal service, and indeed of absolute necessity to the life of the animal inclosed; since it is by means of this that it holds a communication with the external air, and its posterior stigmata are placed as those of the rest of the fly-worms, near the hinder extremity of the body, and that part were they are is always placed directly against this hole in the tumor. When the tumor is of a considerable size, these may be seen by the naked eye; and when

when ſmaller, the help of glaſſes will always diſcover them; the place where they are ſituated being rendered the more conſpicuous and obſervable by two brown creſcents placed round them.

Theſe worms may be properly enough ſtiled the inhabitants of animal galls, ſince the tumors which contain them are truly analogous to the galls of the oak and other the like vegetable excreſcences.

The hole in theſe tumors is not only uſeful to the animal for a breathing place, but it has another not leſs neceſſary uſe; which is to let off a quantity of abundant matter formed in the tumor, which would, if confin'd there, occaſion a large abſceſs, and choak and deſtroy the animal.

If theſe worms were endued with the qualities of thoſe of the common fleſh-fly, and had hooks at their head-part, to tear and pull the fleſh in pieces, the creature who had thirty or forty of theſe gnawing devourers in its back, preying upon its fleſh at once, would be in a very miſerable ſtate: but this is by no means the caſe, the creatures have no organs to tear its fleſh with, they only live on the matter found in the abſceſs, and give the creature no great pain; being only like ſo many tents kept in a wound neceſſary to be preſerved open, or ſo many peas in iſſues.

The worms may at any time be diſlodged from theſe tumors by a moderate preſſure, and made to come out at the hole of the tumor. This, tho' it appear conſiderably too little, yet anſwers the purpoſe; as the body of the worm well enough bears preſſure, and it is only neceſſary, in order to get them out whole, to renew the force upon the tumor, for the puſhing out every ſeparate ring of its body.

While theſe worms are young, they are white, like thoſe of the common fleſh-fly; but when they grow towards their full ſize, they become ſomewhat brown They are of different ſizes, as is uſual with the worms of other flies; thoſe which are to give the female fly being always the larger, and thoſe which give the male the ſmaller. The larger of theſe are conſiderably more than an inch long, and more than half an inch thick in the fulleſt part of their bodies.

They have nothing very remarkable in their ſhape; their anterior part is ſomething ſmaller than their poſterior, and they have no legs. They are compoſed of eleven rings, counting that for one where the mouth is placed; and of theſe the eighth is the largeſt. Theſe rings are not quite circular, being ſomewhat flatted on one ſide; but what is moſt remarkable is, that the flatter ſide is the back, and hence the creature is, contrary to the uſual cuſtom of theſe inſects, hollow, as it were, on the back, and convex on the belly: and there is a good reaſon for this, ſince, as all the other worms which are deſtined to crawl upon a flat ſurface ought to have their bellies flat, that they may touch it in as many points as may be, and the creature be by that means kept ſteady, ſo this creature which inhabits the concave ſurface of a cavity, ought, in order to have its belly touch in as many points as may be, the ſurface it has to crawl upon, to have it, as it is found, tolerably convex.

The worm has ſix longitudinal furrows on its back and ſides, which interſecting the channellings of the rings, make its ſurface very rough and uneven: but beſides this, the whole intermediate ſpaces appear chagrined, and when examined by the microſcope, are found to be covered with yellowiſh prominent triangular bodies.

As this worm has no legs, it is eaſy to determine, that theſe innumerable ſmall protuberances were allotted it, in ſome ſort, to ſupply the place of them, to fix itſelf by to any place, and to aſſiſt it in moving; and may, beſides this, ſerve to the continual irritation of the inſide of the tumor, and keep up the ſeparation of a matter neceſſary to the creature's life. When the worm has attained its full growth, and is to make its way out of the hole in the tumor, this, as yet, appears much too ſmall to give it paſſage. Nature, however, has inſtructed this worm to do what our ſurgeons practiſe on a like occaſion; when they are to open the orifice of a wound, they often do it by means of large tents; the creature incloſed in this tumour makes the hinder part of its own body ſupply the office of a tent on this occaſion: for three or four days before it is to make its way out, it forces its hinder part into the orifice, and keeps it there a long time; then takes it back, and afterwards thruſts it thither again, and continues without intermiſſion repeating this operation; and when, by this means, the hole is ſufficiently enlarged, it crawls out ſlowly, with its hinder part backward.

As ſoon as it is out of its habitation, it falls to the earth, where it crawls ſlowly about till it finds a place where it may reſt, to go through its ſeveral changes, under a ſtone, or in any quiet place.

Stags and ſome other animals are ſubject to theſe worms in the ſame manner as oxen, and the ſeveral ſtages they go through in the tumors on theſe animals are the ſame with thoſe of the ox.

When they have fixed upon a place to reſt in for their changes, they loſe all motion, and their ſkin becomes black and hard, and makes a ſhell for their remaining in through their ſucceeding changes.

When the time of the egreſs of the fly is come, it appears a two-winged one indeed, but ſo extremely like the humble-bees of a middling ſize, that it is not eaſily to be diſtinguiſhed for what it is: one humble-bee cannot be more like another, than theſe flies are to that ſpecies of them; their bodies are as ſhort, all of the ſame colours, and are even more hairy.

This fly, cloſely examined, appears to be of the ſecond claſs, and to have a mouth without teeth or lips, and its mouth very ſmall. The antennæ are ſhort, rounded at their ends, and of a gloſſy hue. The reticular eyes are of a deep cheſnut colour.

The female has, in the under and hinder part of her body, a cylindric tube, which ſhe can thruſt out at pleaſure, and which is the inſtrument with which ſhe pierces the ſkin of the animal, to depoſit her egg. *Reaumur* Hiſt. Inſect. Vol. 4 p. 503, ſeq. to 537.

OX-*gang*, or OXENGATE. A term uſed in Scotland for a portion of arable land, containing 13 acres. Tr. Pract. Geom. P. 86.

OXALME, in the materia medica of the antients, the name of a compoſition of vinegar and brine, made by a ſolution of ſea-ſalt in water. This was uſed externally in ulcers, and ſuppoſed of great ſervice againſt the bites of venomous animals; and for the curing childrens ſcabby heads. It was alſo uſed as a ſtyptic poured into wounds, and was ſometimes given warm in clyſters; but theſe were always followed by thoſe of milk.

OXELÆUM, a word uſed by many authors to expreſs a mixture of vinegar and oil, for outward application, in caſes of bruiſes and other injuries.

OXUCIÆ, in natural hiſtory, the name of a genus of foſſils of the claſs of the *ſelenitæ*, but of the columnar not the rhomboidal kind. The word is derived from the Greek ὀξὺς ſharp, and κίων a column; and expreſſes a body of a columnar form, and pointed or ſharp at the ends. The *ſelenitæ* of this genus conſiſt of ſix equal planes, having their top or bottom no broader or more depreſſed than the others; and in this differing from the *iſchnambluces*, or flatted columnar *ſelenitæ*, as they do from the *iſambluces* or *cryſtaliform*, but broken ended ones, by having their ends naturally tapering off to a point. See Tab. of Foſſils, Claſs 2. *Hill's* Hiſt. of Foſſils, p 121.

The bodies of this genus, like thoſe of the other genera of the columnar *ſelenitæ*, are liable to a longitudinal crack in their middle; and this ſometimes includes a little clay, in form of an ear of graſs. See SELENITES.

Of this genus there are only two known ſpecies: 1. A fine kind, with thin flakes and tranſverſe filaments, found in the clayey banks of the river Neu, near Peterborough, in Northamptonſhire; and, 2. A dull kind, with thick plates and longitudinal filaments. This is not uncommon in Yorkſhire, and lies ſometimes in a yellow, ſometimes in a blue clay. *Hill's* Hiſt. of Foſſ. p. 141, 142.

OXYA, in botany, a name by which many authors, eſpecially the Greeks, have called the *fagus* or *beech-tree*. *J. Bauhin*, Vol. I. p. 117.

OXYBLATTA, among the antients, is uſed to denote a bright and gloſſy kind of purple colour. *Hoffm.* Lex. in voc.

OXYCEDRUS, in botany, a name given by ſome authors to the *cedrus folio cupreſſi*, or the *berry-bareing cedar*. *Chabræus*, p. 72.

OXYCOCCUS, in botany, the name of a genus of plants, the characters of which are theſe: the flower is of the roſaceous kind, being compoſed of ſeveral petals, arranged in a circular form; the cup finally becomes a roundiſh fruit or berry, which is divided into four cells, containing roundiſh ſeeds.

The ſpecies of *oxycoccus* enumerated by Mr. Tournefort, are theſe: 1. The common *oxycoccus*, or *moor-berries*; and, 2. The broad-leaved *oxycoccus*. *Tourn.* Inſt. p. 655.

OXYGARUM, a word uſed by the antients to expreſs a mixture of vinegar and *garum*, which is a pickle for the preſerving fiſh, or a ſimple mixture of ſea-ſalt and water.

OXYGLUCA, a word uſed by the antients to expreſs a liquor made of a mixture of honey, water, and vinegar. The common way of making it was by macerating the combs, after the honey was preſſed out, in water; and then adding a ſmall portion of vinegar, to give it a tartneſs. It was ſometimes made without the addition of the acid, and made a weaker ſort of mead, uſed as a common drink in hot weather. Galen ſays, it was the ſame with the *apomeli*.

OXYLIPES, a word uſed by ſome authors as a name for bread, which has a mixture of vinegar in it; intended ſometimes for eating, ſometimes for medicinal uſes.

OXYMYRSINE, in botany, a name by which ſome authors have called the *ruſcus*, or *butcher's broom*.

OXYPHŒNICON, in botany, a name uſed by ſome authors for the tree whoſe fruit is the *tamarind* of the ſhops. Mant. Exot. p. 10.

OXYPYCNI, ὀξύπυκνοι, in the antient Greek muſic, was a name given to ſuch chords as formed the higheſt ſounds of the *ſpiſſa*. There were five *oxypycni* in the ſcale. See the articles PYCNI and SPISSUM.

OXYREGMIA, a word uſed by the antients to expreſs acid eructations.

OXYRYNCHUS, in zoology, the name of a fiſh of the truttaceous kind, called by ſome *hautin*, and *outin*. It is caught frequently in the Engliſh and other ſeas, and is frequently carried to market in Holland among the whitings. It is very much of the ſhape and figure of the trout, but a little flatter, and is covered with large white ſcales. The back is of a ſomewhat duſky colour, and the lines on the ſides a little bent near their origin. The tail is forked; but the mark by which it is moſt readily diſtinguiſhed from all other fiſh of this genus, is the figure of its ſnout, or upper jaw, which runs out beyond the under, and goes off rounding and tapering to a point, making in the whole a ſort of conic figure. The head is ſomewhat tranſparent. It has no teeth, but a conſiderably rough tongue. *Aldrovand.* de Piſc. l. 5. c. 24.

OXYS, in botany, the name by which authors call *wood-ſorrel*. The characters of this genus of plants are theſe: the flower conſiſts of one leaf formed into a bell, and wide open at the mouth, where it is alſo divided into ſeveral ſegments. From the cup of the flower there riſes a piſtil, which is fixed like a nail into the bottom of the flower, and ripens into an oblong membranaceous fruit, uſually divided into five cells, opening outward from the baſe to the apex, and full of ſmall ſeeds, which uſually fly out forcibly on the touching the ſeed-veſſel, by means of the elaſticity of ſome of its parts. *Tourn.* Inſt. p. 89.

The ſpecies of *oxys* enumerated by Mr. Tournefort, are theſe: 1. The common white flowered one, called by authors *trifolium acetoſum*, and *alleluja flore albo*. 2. The purple flowered kind. 3. The blue flowered kind. 4. The common yellow one. 5. The upright American yellow flowered one. 6. The fibroſe rooted American one, with red flowers. 7. The yellow ſhrubby American *wood-ſorrel*, having the appearance of the ſtinking trefoil. 8. The ſcaly rooted purple *wood-ſorrel* of Virginia. 9. The bulboſe-rooted African *oxys*, with roundiſh leaves and with purple ſtalks and large purple flowers. 10. The bulboſe-rooted round-leaved African *oxys*, with green ſtalks and large purple flowers. 11. The Æthiopian bulboſe-rooted *oxys*, with heart faſhioned leaves, and large purpliſh white flowers. See Tab. 1. of Botany, Claſs 1.

The ſeveral ſpecies of this plant are uſually diſtinguiſhable even when they are not in flower, by their having their leaves growing regularly three at the top of every ſtalk; and being each uſually of the figure of a heart at cards, and theſe are generally of an agreeably acid flavour. See SORREL.

OXYSAL-*diaphoreticum*, the name of a compound medicine greatly recommended by ſeveral authors, and invented by Angelus Sala. The manner of preparing it is this: take fine ſalt of carduus benedictus, put it into an earthen pot, and pour upon it gradually ſome ſtrong wine-vinegar, or ſpirit of ſugar; continue to pour this on till the ebullition ceaſes and an agreeable ſmell ariſes, and the matter has an agreeable tho' ſomewhat acid taſte; let all the humidity from this mixture be evaporated over a gentle heat, and after this, let all the ſalt be again diſſolved in water, and ſet in digeſtion in balneo mariæ for eight days: a liquor of a beautiful and pellucid colour is there produced, which, when poured carefully off into another veſſel, is to be again evaporated to a dryneſs with a very gentle heat, and the remaining matter, which is the ſalt, is to be collected together, and kept in a phial carefully ſtopt; for it is ſubject to run, if left to the acceſs of the air, like the common alcali ſalts.

OXYSCHŒNOS, in the materia medica, the name of the *juncus acutus capitulis ſorgli*; or *hard pricking large ſea-ruſh*. *Dale*, Pharm. p. 258. See JUNCUS.

OXYTOCHA, in medicine, a term uſed by many authors to expreſs ſuch medicines as are given to promote delivery.

OXYTRIPHYLLUM, in botany, a name uſed by ſome authors for the *trifolium bituminoſum*, or *ſtinking trefoil*. *Chabræus* p. 110.

OYSTER, or OISTER, *oſtrea*, in zoology. See the article OSTREA.

The *oiſter* affords the curious in microſcopic obſervations a very pleaſing entertainment. In the clear liquor many little round living animalcules have been found, whoſe bodies being conjoined, form ſpherical figures, with tails not changing their place otherwiſe than by ſinking to the bottom, as being heavier than the fluid; theſe have been ſeen frequently ſeparating, and then coming together again. In other *oiſters*, animalcules of the ſame kind were found, not conjoined, but ſwimming by one another, whence they ſeemed in a more perfect ſtate, and were judged by Mr. Lewenhoek, to be the animalcules in the row or ſemen of the *oiſter*.

A female *oiſter* being opened, incredible multitudes of ſmall embryo *oiſters* were ſeen, covered with little ſhells, perfectly tranſparent, and ſwimming along ſlowly in the liquor: and in another female, the young ones were found of a browner colour, and without any appearance of life or motion.

Monſieur Job'ot alſo kept the water running from *oiſters* three days, and it appeared full of young *oiſters* ſwimming about nimbly in it; theſe increaſed in ſize daily, but a mixture of wine, or the vapour of vinegar, killed them.

In the month of Auguſt *oiſters* are ſuppoſed to breed, becauſe young ones are then found in them. Mr. Lewenhoek, on the fourth of Auguſt, opened an *oiſter*, and took out of it a prodigious number of minute *oiſters*, all alive, and ſwimming nimbly about in the liquor, by means of certain exceeding ſmall organs, extending a little way beyond their ſhells; and theſe he calls their beards. In theſe little *oiſters* he could diſcover the joinings of the ſhells, and perceived that there were ſome dead ones, with their ſhells gaping. Theſe, tho' ſo extremely minute, are ſeen to be as like the large *oiſters* in form, as one egg is to another.

As to the ſize of them, he computes, that a hundred and twenty of them in a row would extend an inch; and conſequently, that a globular body, whoſe diameter is an inch, would, if they were alſo round, be equal to a million, ſeven hundred and twenty-eight thouſand of them. He reckons three or four thouſand are in one *oiſter*, and found many of the embryo *oiſters* among the beards; ſome faſtened thereto by ſlender filaments, and others lying looſe: he likewiſe found animalcules in the liquor five hundred times leſs than the embryo *oiſters*. *Lewenhoek* Arcan. Nat. T. 4. p. 513.

It is not very uncommon to ſee on *oiſter* ſhells, when in a dark place, a ſhining matter or bluiſh light, like a flame of brimſtone, which ſticks to the fingers when touched, and continues ſhining and giving light for a conſiderable time, tho' without any ſenſible heat. This ſhining matter being examined with a microſcope, was found to conſiſt of three ſorts of animalcules: the firſt, whitiſh, and having twenty-four or twenty-five legs on a ſide, forked, a black ſpeck on one part of the head, the back like an eel with the ſkin ſtripped off. The ſecond ſort, red, reſembling the common glow-worm, with folds on its back, but legs like the former; a noſe like a dog's, and one eye in the head. The third ſort, ſpeckled, with a head like a ſoal, with many tufts of whitiſh hairs on the ſides of it. Some much larger and greyiſh might be ſeen, having great heads, two horns like a ſnail's, and ſix or eight whitiſh feet; but theſe did not ſeem to ſhine. Philoſ. Tranſact. N. 279.

As the bodies of lobſters, and ſome other ſorts of fiſh, tainted fleſh, rotten wood, and other ſubſtances, are ſometimes found to ſhine with a light like that on *oiſter* ſhells, may it not very probably proceed from the ſame cauſe? Some alſo have gone ſo far as to imagine the willow-wiſp, ſo common in fenny countries, to be only a collection of flying inſects, which emit light from ſome part of their body, as the glow-worm and lantron-fly do; and the place, motion, and ſome other circumſtances of that lambent flame, as it is called, ſeem, indeed, not a little to favour that conjecture. *Baker's* Microſcope, p. 241.

Foſſile-OYSTERS. The greateſt bed of *foſſile-oiſters* any where known of, is that near Reading, in Berkſhire. They have the entire ſhape, figure, and are of the ſame ſubſtance with the recent *oiſter* ſhells, and yet muſt have lain there for a long time, the oldeſt hiſtories that mention the place giving an account of them. They are extended over no ſmaller a ſpace than ſix acres of ground, and juſt above them there is a large ſtratum of a greeniſh loam, called by ſome writers a green earth, and by others a green ſand. It is compoſed of a crumbly marle, and a very large portion of ſand. Under them there is a thick ſtratum of chalk. They all lie in a level bed, and as the ſea comes no where near this part of the kingdom, it ſhould ſeem, that the deluge only could give place to them here. It has been idly imagined by ſome, that the Roman ſoldiers once quartered there, threw away theſe ſhells from the *oiſters* they fed on in vaſt quantities, but this is anſwered by obſerving, that the ſtrata above the ſhells are natural, and have never been dug thro' till the time of finding the ſhells.

The *oiſter* ſhells and green earth together, make a ſtratum of about two foot thick; and over this, a much thicker ſtratum, of a bluiſh and very brittle clay, but this has never been dug through, except where we find the ſhells. The people call this *piercy-clay*, and ſay it is fit for no uſe. This bed of clay is about a yard deep, and above it is a ſtratum of fuller's earth, about two foot and an half deep. It is of a very good kind, and is uſed by the clothiers. Over this there lies a ſtratum of a fine white ſand, unmixed either with the clay or fuller's earth: this is near ſeven foot deep, and above this there is a ſtratum of a ſtiff red clay, of which they make tiles in the place. This is covered with a little vegetable mould, and the depth of this ſtratum of tile-clay cannot be aſcertained, becauſe of the unevenneſs of the hill.

Theſe *oiſters* are ſometimes found whole, but more uſually in ſingle ſhells. When they are in pairs, there is uſually ſome of the green ſand found within them: they ſeldom ſtick very faſt together, ſo that unleſs very carefully taken up, it is not eaſy to get them in pairs. Phil. Tranſ. N. 261, p. 484.

OYSTER-*ſhells*. Theſe are an alcali of a more powerful kind than is commonly ſuppoſed, and probably are in reality much better medicines than many of the more coſtly and pompous alkalies of the ſame claſs. The proof of alkalies is in their ſolution by acid ſpirits; and Mr. Homberg found, that they diſſolved much more eaſily in the acids of nitre and ſea-ſalt, than pearls, coral and the reſt; which he ſuppoſes owing to their containing in the body of the ſhell a conſiderable portion of ſal-ſalſus, which is eaſily perceived upon the tongue, and which keeps the whole ſubſtance of the ſhell in a ſort of half diſſolved ſtate. Theſe ſhells are found to produce very great effects on the ſtomach, when injured by acid humours; and Mr. Homberg is of opinion, that this their eaſineſs of ſolution is one great reaſon of their good effects, and that the quantity of ſal-ſalſus

which it contains, contributes not a little towards it, ſince we are not to look upon that as a mere ſalt, but a ſalt of a peculiar kind, formed of ſea ſalt by the organs of the animal, and the ſeveral fermentations it undergoes in the body of it, in the ſame manner as the nitrous and other ſalts of the earth ceaſe to be nitrous, &c. as ſoon as they have been blended with the juices of plants, and form with them a ſalt peculiar to that plant; and this is plainly the caſe in regard to this ſalt, ſince it is evidently of a more penetrating taſte, and of a different ſmell, from the ſalt left by the ſea water between the ſeveral external ſcales, or flakes of the ſhell.

As *oiſter* ſhells were found by Mr. Homberg to be a very valuable medicine, and as one of the common methods of preparing them is by calcination, which he obſerves cannot but much impair their virtues, he gives the following method of preparing them for taking inwardly, which was what he always uſed:

Take the hollow ſhells of the *oiſters*, throwing away the flat ones as not ſo good; waſh them perfectly clean, and then lay them to dry in the ſun; when they appear dry, beat them to pieces in a marble mortar, they will be then found to contain yet a large quantity of moiſture; lay them again in the ſun till perfectly dried, and then finiſh the powdering them, and ſift the powder thro' a fine ſieve. Give twenty or thirty grains of this powder every morning, and continue it three weeks or a month. Mem. Acad. Par. 1700.

OYSTER-*worm*, in natural hiſtory, a name given by writers to a kind of ſmall worm found in *oiſters*, which ſhines in the dark, in the manner of the glow-worm; but with an univerſal light, and not in a peculiar part only, like this animal.

The firſt obſerver of theſe *oyſter-worms* was Mr. De Lavoye, who communicating his obſervations to Mr. Auzout, gave occaſion to a very diſtinct account of them from this author.

The firſt thing that preſents itſelf on the opening the *oiſters* which contain theſe worms, is only a ſort of ſhining clammy moiſture, which appears like a ſtar of a blueiſh colour, and being drawn out, will extend itſelf to near half an inch long, and ſhine as much for that whole length as in the contracted ſtate: it will alſo ſhine for ſome time after it is taken out of the *oiſter*.

On a ſtricter obſervation, theſe ſhining ſubſtances are found to be real living worms, and there are indeed three diſtinct ſpecies of them. One ſort is whitiſh, and has twenty-four or twenty-five feet on each ſide: there is a black ſpeck on one ſide the head, and the back exactly reſembles that of an eel, when the ſkin is ſtriped off. The black ſpeck in the head is certainly an eye, and it is remarkable that the creature has but one. The ſecond ſort of theſe worms, is red: this alſo has but one eye: its body is made up of ſeveral rings; its noſe is like that of a dog, and it has the ſame number of feet with the former. The third ſort is very different from the other two; it is ſpeckled, and its head is like that of a ſoal, and has a tuft of hair on each ſide. There are other worms found alſo in the *oiſter*, particularly a large greyiſh one with two horns, a great head, and ſeven or eight whitiſh feet; but theſe do not ſhine. The two firſt ſorts are eaſily miſtaken for ſhining moiſture only, their ſubſtance being ſo tender, and eaſily reſoluble, that on the leaſt ſhaking or touching, they turn into a viſcous jelly. This, however, has the property of ſhining as much as the living worm, and when taken from the ſhell, will ſhine on the obſerver's fingers for twenty or thirty ſeconds; and if any part of this matter be let to fall to the ground, it ſhines as long, and exactly reſembles a piece of burning brimſtone. Sometimes when ſhaken off nimbly, it becomes a ſhining line, which diſſipates itſelf before it comes to the ground. The ſhining matter in this caſe, is in ſome whitiſh, in others reddiſh; but yet in both caſes it gives a violet appearance to the eye. The white ones are the tendereſt of all: theſe ſo eaſily burſt, and become a mere lump of jelly, that if it were not for the feet which are ſeen among it, one would ſcarce imagine that they were ever worms, or any thing living. When they are large and robuſt, they move their heads and tails about, and this is a great addition to the luſtre of their ſhining; every motion of this kind giving a flaſh of light brighter than the reſt. On forcibly ſhaking the *oiſter* in the dark, the whole ſhell is ſometimes ſeen full of lights, which are now and then as big as the finger's end; after this, a great deal of this clammy matter, both red and white, may be obſerved; ſo that it is probable great numbers of the worms are burſt in their holes. In the ſhaking it may be diſtinguiſhed, that their holes run into, and communicate with one another, like the holes made by worms in wood. This light occurs more frequently in large, than in ſmall *oiſters*. there are few of theſe large ones that do not yield it in the ſhells, and in ſome it is ſeen in the *oiſters* themſelves.

Thoſe ſhells which are viſibly pierced by the worm, more frequently emit the light than thoſe which are not; and the convex ſhell more than the flat one. The worms are not apt to give light when irritated, but if they do, it laſts only a little time; but when they are at reſt, the light they give uſually laſts ſeveral hours. The outſide of the ſhell being a little ſcaled, the communication of the holes may be ſeen; the form of the worms is generally deſtroyed in doing this, but there is the jelly like moiſture left, and this ſmells like the *oiſter* liquor. Journal de Scavans, 1666.

OZE, a word uſed by ſome writers to expreſs a *fœtor*, or *ill ſmell of the mouth.*

OZEMAN, a word uſed by ſome of the chemical writers for the white of an egg.

OZO, a word uſed by ſome of the chemical writers for *arſenic*, or *ratsbane.*

P.

PABOS, in botany. See CAAMINI.

PACA, in zoology, the name of an American animal of the Guinea-pig kind, having the general characters of the rat kind, and the voice and hair of the hog.

This is the largest of all the animals of this kind, being of the size of a small pig, and usually very fat. Its head is like that of a rabbit, and its beard long, and resembling that of the hare: its ears are naked, and a little pointed; its nostrils very wide and large; the upper chop is longer than the under one, and the hinder legs than the fore ones. Its feet have all four toes a-piece; its hair is hard and harsh, like that of a hog, and of a dusky brown colour: it has several grey spots disposed in a longitudinal direction along the sides, and its belly is white. It does not use its fore feet in the nature of hands, as the other species do, but eats it on the ground in the manner of the hog. It is usually fat, and the flesh very well tasted. *Ray*'s Syn. Quad p. 226.

PACAMO, in zoology, the name of a long-bodied fish of the mustela kind, caught among the rocks, and of a very well-tasted flesh It is usually about eleven fingers long, and grows narrower and smaller toward the tail. Its head is large, broad, and thick. Its mouth is of the shape of a half-moon, and has very solid, but not sharp teeth. Its eyes are small, black, and placed very close together. Behind the gills are two fins soft and skinny; and lower on its belly, two more. Its back and belly fin, which runs from the middle of the back to the anus, is very soft and skinny also; the tail fin is more than a finger long, and is skinny like the rest. The skin is smooth, and has on each side four rows of white spots running from the gills to the tail. Its skin easily slips off from the body like that of an eel. *Marggrave*'s Hist. Bras. p. 113.

PACHODECARHOMBIS, in natural history, the name of a genus of fossils, of the class of the selenitæ.

The word is derived from the Greek παχυς thick, δεκα ten, and ῥομβος, a *rhombus*, and expresses a thick rhomboidal body, composed of ten planes. See Tab. of Foss. Class 2.

The characters of this genus are, that the selenitæ of it consist of ten planes; but as the top and bottom in the leptodecarhombes, or most common kind of the selenitæ, are broader and larger planes than any of the rest, the great thickness of this genus, on the contrary, make its four longer planes in all the bodies of it, meeting in an obtuse angle from its sides, its largest planes. *Hill*'s Hist. of Foss. p. 120.

Of this genus there are only four known species: 1. A very pellucid one, with slender transverse striæ. This is frequent in the clay-pits of Northamptonshire, and some other counties; and the ordinary people have an opinion, that it is good to stop hæmorrhages; whence it has acquired among them the common name of *staunch*. 2. A dull-looking kind, with very fine transverse filaments. This is found in the clay-pits of Northamptonshire, Staffordshire, and Yorkshire. 3. A fine and beautiful kind, with very slender longitudinal filaments. This is common in Yorkshire, and seems almost peculiar to that county; it is not only found there in digging, but frequently lies on the surface of the earth. And 4. A brown pellucid kind, found very frequently in Germany, and sometimes in England. *Hill*'s Hist. of Foss. p. 130—133.

PACHUNTICA, a term used by some medical writers to express incrassating medicines.

PACOS, in zoology, the name of a species of camel, usually, but very improperly accounted a species of sheep; and known among many by the name of the *Indian sheep*, or *Peruvian sheep*.

It very much resembles that species of camel usually known by the name of *glama*, and found in the same countries; but this is much smaller, and is much less tractable, and a very obstinate animal.

The reason of this creature's having been accounted a sheep, is, that its hair is so long as to resemble wooll, and it is cloathed prodigiously thick with it. Its head and neck alone, have more wooll on them than the whole body of our largest sheep. Its body is cloathed in the same proportion with a woolly hair, equally fine. It is a much weaker creature than the glama, and is never used for carrying burthens, but is kept as our sheep for the sake of its wooll and its flesh, which is very well-tasted, and is a rich food. *Ray*'s Syn. Quad. p. 147.

PACQUING, in natural history, a name given by the people of the Philippine islands to a small bird of the sparrow kind, but very beautifully variegated. It feeds on the seeds of grass.

PADDLE, in glass-making, the name of an instrument with which the workman stirs about the sand and ashes in the calcar. *Neri*'s Art of Glass, Appendix.

PÆCILIA, in ichthyology, a name given by Schoneveldt [a], and some others [b], to the fish called by most authors the *mustela fossilis*. It is properly a species of *cobitis*, and is called by Artedi the *bluish cobitis*, with five longitudinal black lines on the body.—[[a] *Schoneveldt* de Pisc. [b]*Willughby*'s Hist.Pisc.p. 124.]

PÆDARTHROCACES, in surgery, is a disease of the bones, raising them into tumors near the joints, and differing from the spina ventosa, in that it is not attended either with violent pains, or erosions of the bone and adjacent parts. The word is derived from the Greek παις a child, αρθρον a joint, and κακον an evil, signifying that it is a disorder of the joints, to which children are principally subject; which is the case, because the bones of children being softer than those of adults, are therefore the more easily distended by humors, and more frequently raised into tumors: these are hard in this case, and the adjacent soft parts are not inflated, and are free from redness, inflammation and pain. It is, however, to be observed, that this disorder, tho' at first very different from the spina ventosa, is sometimes known to degenerate into that disorder. *Heister*'s Surg. p 261.

PÆDEROTA, in botany, a name by which Linnæus has distinguished a plant nearly related to the veronicæ or speedwells, and called *bonarota*, by Micheli. This, in the Linnæan system of botany, is also a distinct genus of plants, the characters of which are, that the cup is a perianthium, divided into four segments, and remaining after the flower is fallen. The several segments are strait and pointed; the flower is composed of a single petal, which forms a cylindric tube, nearly of the length of the cup, placed erect at its extremity, and divided into two labia; the upper of which is long, hollow, and narrow; the under expanded, but somewhat erect, broadest in its upper part, lightly divided into three segments, and those all equal. The stamina are two filaments bent downward, and of the same length with the cup: the antheræ are somewhat erect: the pistil has a roundish germen, a thread-like style of the same length with the stamina, and a truncated stigma. The fruit is a flatted capsule of an oval figure, but bifid and pointed at the top, consisting of two cells with four valves. The seeds are very numerous, oblong, and obtuse, and adhere to a columnar receptacle. *Linnæi* Genera Plantar. p. 4.

PÆDEROTA, among some of the old botanical writers, is also a name given to the *acanthus*, or *bear's-breech*. *Ger.* Emac. Ind. 2.

PÆDOTHYSIA, Παιδοθυσια, in antiquity, an inhuman custom that prevailed among the antient Heathens of sacrificing their children. Thus it is related in the Scriptures, that the king of Moab being besieged by the Israelites in his capital, and reduced to great straits, took his eldest son that should have reigned in his stead, and offered him for a burnt offering upon the wall, on which the siege was raised. 2 *Kings* iii. 27.

From Phœnicia this cruel practice passed into Europe, and Africa, and spread itself far and wide: and it is reported, that the Mexicans are, at present, guilty of it. *Hofm.* Lex. in voc.

PÆNULA, among the Romans, a thick garment fit for a defence against cold and rain. *Pitisc.* Lex. Ant. in voc.

PÆONIA, *piony*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, consisting of several petals disposed in a circular form. The cup is also composed of several leaves, and from it arises a pistil, which finally becomes a fruit, composed, as it were, of several capsules collected into a head: these all bend downwards, and are usually hoary; they split open longitudinally when ripe, and contain roundish seeds.

The species of *piony*, enumerated by Mr. Tournefort, are these: 1. The common male *piony*, with a shining blackish flower. 2. The male *piony*, with flesh-coloured flowers. 3. The white-flowered male *piony*. 4. The male *piony*, with larger segments to the leaves. 5. The great male *piony*, with flesh-coloured flowers. 6. The late flowering male *piony*. 7. The common female *piony* 8. The narrower-leaved female *piony*. 9. The broader-leaved female *piony*. 10. The dwarf rose-flowered winter *piony*. 11. The purple-flowered *piony*, with finely divided leaves, hoary underneath. 12. The whitish-flowered *piony*, with leaves hoary underneath. 13. The aquiline-leaved *piony*. 14. The orange-coloured *piony*. 15. The *piony* with variegated flowers. 16. The *piony* with very deep-red flowers. 17. The Constantinople *piony*, with pale-red flowers. 18. The large-flowered double deep red *piony*. 19. The smaller-flowered double deep red *piony*. 20. The common *piony*, with double large pale red flowers. 21. The common *piony*, with smaller double pale red flowers. 22. The smaller-flowered whitish double *piony*. *Tourn.* Inst. p. 273. See PIONY.

PÆONITES, in natural history, a name given by some writers to the stone called by others *pæanites*, and esteemed of great use

ufe to women in labour. It feems to have been called *pæonites*, from Pæonia in Macedonia, where it was found.

PAGANELLUS, in ichthyology, the name of a fifh of the fea-gudgeon, or rock-fifh kind, called by authors *gobius maximus marinus flavefcens*. This name, however, which was given it by Rondeletius, is a very erroneous one, fince it is fmaller than the common kind, which it much refembles; it is alfo of a paler colour, and has a fine yellow line furrounding the edge of its firft back fin, and has but a flight furrow on its back, whereas that has a much larger one. Its head alfo is fhorter, and its jaws more tumid; and its belly fins more regularly connected into the fhape of a funnel. It is common in the Mediterranean and other feas, and is frequently brought to market at Rome, Venice, &c. *Willughby*'s Hift. Pifc. p. 207. See the article GOGET.

PAGANINA, an Italian word ufed by fome authors to exprefs the firft excrements of children: thefe dried and reduced to power, are efteemed by fome a very great and powerful medicine againft epilepfies. It is to be taken in fmall dofes every day, for fome time.

PAGEL, in ichthyology, a name given by the Spaniards to that fifh which authors in general call the *erythrinus*, or *rubellio*, and fome the *xathus* and *pagrus* It is properly a fpecies of the *fparus*, and is diftinguifhed by Artedi from the reft of that genus, by the name of the *filver-eyed red bodied fparus*. See the article SPARUS.

PAGOYUM, a word ufed by Paracelfus and his followers, to exprefs an imaginary being which prefides over, or is the occafion of difeafes, whofe caufes are lefs known, and which have been fuppofed to arife from inchantment. Such is the doctrine of this ftrange writer, and on this fubject he has written a treatife called *Pagoyus*.

PAGRUS, in ichthyology, the name of a fea-fifh, known in Englifh by the name of the *fea-bream*. It is a confiderably large fifh, growing fometimes to ten or twelve pounds weight. It is very broad in proportion to its length, and is alfo confiderably thick; its head is flatted at top, and at the bafis of the gill fins, it has on each fide a large black fpot. Its gill-fins are large and long, and the extremities of all its fins are hid, and as it were involved in fkin, which is a very fingular circumftance in regard to this fifh. The eyes are large, and their hairs white, and the mouth is frequently of a fine red within; it has broad teeth in the forepart of its mouth, and rough tubercles in the place of teeth in the hinder. Its tail is forked, and it has one long back-fin; the nerves, or rays of the anterior part of which are fharp and prickly, and thofe of the hinder part foft and fmooth to the touch. It is caught in confiderable plenty in the Mediterranean, and is common in the markets of Italy. Some account it a very delicate fifh, but many think it eats too dry. See Tab. of Fifhes, N. 58. *Aldrovand* de Pifc. l. 2. c. 7. *Rondelet.* de Pifc. l. 5. c. 15. p. 142. *Gefner* de Pifc p. 173.

PAGRUS is alfo ufed by Joannes Cuba, and others, for the fifh commonly called *dentex*, the *fynodon*, and *fynagris* of the Greeks. It is a fpecies of the fparus, and is accurately diftinguifhed by Artedi, by the name of the *variegated fparus*, with a fharp back, and with four large teeth. See SPARUS.

PAGRUS is alfo a name given by Paulus Jovius, and fome other authors, to the fifh called *erythrinus* and *rubellio*, and by Appian, *xathos*. It is of the fparus kind, and is diftinguifhed by Artedi, by the name of the *filver-eyed red bodied fparus*. See PAGAL.

PAGRUS *indicus*, a name by which fome authors have called the Eaft Indian fifh, more ufually known by the name of *brama faxatilis*. *Ray*'s Ichthyology, Append. p. 1. See the article BRAMA *faxatilis*.

PAIN *d'abeiles*, a word ufed by fome to exprefs the yellow fubftance found concreted in lumps on the legs of bees, and fuppofed by the generality of the world to be real wax

Experiments made by Mr. Reaumur and others, have fufficiently proved that this fubftance is not wax, nor has it any of the properties of wax; but it alfo appears, that it is the matter out of which wax is finally made.

In tracing this fubftance up to its origin, we find that the bees collect the farina of flowers, which when moulded by their feet into a lump, makes this matter. It is very probable that they feed on this matter, and that after paffing thro' certain changes in their bodies, it becomes wax. This was an opinion fo old as the days of Pliny; fome of the authors he quotes calling this fubftance *ambrofia*, or the food of thefe little deities; but late obfervations overthrow this opinion, till it again got credit under the more accurate examinations made by Mr. Reaumur, on the ftructure and parts of the bee.

Swammerdam exploded this notion, from the orifice of the trunk of the bee being infinitely too fmall to give admiffion to this matter, the feveral particles of which always retained, in the lumps, their original form and fize; and the opinion eftablifhed by this author, of the bees receiving nourifhment only by its trunk, made it neceffary to fuppofe, that only honey, or the faccharine juices of vegetables, could be the food of this creature; fince nothing folid could poffibly be received thro' that minute orifice: but Mr. Reaumur has fufpected even the exiftence of any fuch orifice, or any aperture at all in the trunk, and has plainly proved, that the bee has a real mouth, and that large enough to receive folid food. This mouth is fituated in the anterior part of the head, very near the origin of the trunk, and by means of this, the yellow matter collected on the thighs may be eafily received into the body, and thence evacuated again in form of wax; all the parts of its compofition having been received as nourifhment by the animal, except this indiffoluble fubftance. The poffibility of the bees feeding on this matter, is not, however, all the argument we have in favour of this opinion; for it is evidently feen on diffecting them, that they really do feed on it, their ftomachs being ufually found filled with it, and that in its proper form, the figures of the globules not being deftroyed.

This is a food not only eaten occafionally by the bees, but neceffary to their fupport, and is found ftored up in their hives againft a bad feafon. The combs have their different cells made for different purpofes; and befide that, fome are deftined for receiving honey, and fome for the young worms which are hereafter to become bees; there are fome alfo which ferve to contain this yellow matter, collected on the legs of thefe infects. In fine weather, when more of this matter is collected than is eaten for immediate nourifhment, the bees fcrape off the lumps of it from their legs into fome of the holes, or cells of the combs, where others following their example, there finally become large referves of it; which are eaten on fuch days as they cannot go out in fearch of more.

When one bee has depofited her load of this matter in a cell, and is flown out to work again, another always enters immediately head foremoft into the cell, and flats and preffes down the matter into the bottom of the cell; others afterwards depofit more of it, and others ftill repeat the work of preffing it down; and as they prefs it, they break and bruife it with their teeth, and pour in fome of their honey upon it, and by this means they finally compleat the magazine of food, by rendering the mixt mafs in condition to keep, and to be taken out with great eafe upon occafion. It is evident from all this, that the yellow matter collected on the thighs of bees, and ufually fuppofed to be wax, is really a fubftance which ferves for the food of the bees, and that after it has been divefted of the nutritious matter it contained, it is again thrown out of the body in form of wax. It might be naturally fuppofed from this, that the wax was an excrement voided by way of fæces thro' the anus; but this is by no means the cafe, what is voided by that paffage is true fæcal matter, of no farther ufe or fervice to the animal; and the wax in its perfect form is voided out of the body by the fame paffage by which it was taken in while in its rough ftate, that is, by the mouth; and is, on being thus voided, immediately worked into cells, &c. by the teeth of the animal. This was a difcovery in the œconomy of this little animal referved for that excellent naturalift Reaumur.

Swammerdam, who had ftudied the creature's operations very accurately, had been in no condition to obferve this particular, for want of the advantage of glafs hives; and Maraldi, tho' he had thefe, yet had them fo ill conftructed, that they could not give him an opportunity of feeing with fufficient accuracy.

The teeth of the bee, tho' the principal part concerned in the working the wax, are not, however, the only part; the tongue of the creature is very greatly affiftant on the occafion: it is darted with incredible velocity on the feveral parts of the work, and feems to do great matters toward the forming it. Befide this, the bee has a method of rendering the wax fit for receiving any form, in a manner we do not know any thing of. In order to manage this fubftance, we are obliged to heat it, and it fo becomes ductile; but this is not in the power of the bee, and muft be of very deftructive confequence to the whole if it was, fince the circumjacent parts muft be heated, as well as that on which it was at work, and then they would burft with the load of honey they contain, or break under the weight of the bees at work on them: as this would be a deftructive method, nature has given the animals another; fhe has furnifhed them with a liquid, with which, when the wax is properly wetted, it becomes as foft as a gum, and as ductile as the filaments of filk when fpun from the caterpillar.

The bee collects this yellow matter, which is the prime conftituent of the wax, from whatever flowers happen to be moft plentiful about the hives; and tho' generally yellow, as the farina of moft plants is fo, yet it is fometimes feen in red, or green lumps on their thighs; but whatever be its natural colour, it is always turned yellow before it is difcharged from the body of the animal; and when the ftomach of any of them is diffected, after the feeding on a red fubftance collected from flowers, the farina of which is of that colour, the change is found to be made as to colour in this part, for the whole is found there in form of a yellow jelly. This matter, if taken out of the ftomachs of feveral bees and dryed, is found to be of a difagreeable fmell, like fermented matter, and of a pungency fomewhat refembling that of the volatile falts. Mr. Reaumur was hence induced to try the effect of the volatile falts in turning the bees bread, or rough wax, into perfect wax by digeftions, continued a long time, but in vain. If we may give credit, however, to the German

man Ephemerides, there is a much more eafy way of reducing this matter, while yet contained in the apices of the plant, into true wax; and that without the affiftance of the work of the bees. Mr. David Maja gives an account in thofe papers, that the perfons he employed in beating rofes into conferve, always obferved in the pounding of the rofes, before the fugar was put to them, that a piece of folid but foft matter was found adhering to the peftle of the mortar, which, on a ftrict examination, proved to be true and genuine wax. It appeared from this experiment, that the juice of the petals or leaves of the rofes, was able, by the affiftance of beating, to convert into true wax the farina contained in the apices of that flower. Mr. Reaumur tried what effect the juice of rofes would have on the yellow matter collected on the legs of the bees and on the farina of plants, but no treatment he could give thefe fubftances was ever able to produce wax.

Mr. Reaumur brought it to an abfolute proof, that the bees eat the rough wax or bees bread, by obferving the bees of a certain hive to come home loaded with it every day, feveral times over, during the month of April and a great part of May; and after this, opening and examining the hive they belonged to, there were found no new combs, nor were the old bees enlarged in fize: it is true, that there were fome cells found, filled with magazines of this matter, but as the far greater part was brought to no fort of account, it feems very plain that they had eat it. It is to be obferved, that the bees have their feveral periods of going out in fearch of this matter and of honey: it would be too fatiguing for them to be always thus at work, and to avoid this there is always a very large part of them, even more than half the hive, found at reft within it; thefe are fuch as have worked till they are tired, and the others in turn take this manner of refting, and fend thefe out to work again. *Reaumur*'s Hift. Inf. Vol. X. p. 68. See WAX.

PAINTED *lady*, among the florifts, a term for a particular fort of carnations, the flowers of which have all their petals red or purple on the out fide, and white underneath.

PALA, in botany, a name by which fome authors have called the *nutmeg-tree*. *Pifo*, Mant Arom. p. 173.

PALA, in zoology, a name ufed by fome authors for a fifh of the truttaceous kind, more ufually known by the name of *ferra*. *Willughby*'s Hift. Pifc. p. 185. See the article FERRA.

PALÆSTE, the name of a Greek meafure of length, being the fame with the *dochme* and *doron*, and containing four finger-breadths, or digits.

PALALACA, in natural hiftory, the name given by the people of the Philipine iflands to a bird common among them, and fomewhat refembling the *upupa*. It has a very coarfe and harfh voice; its head is brown, and has a comb or creft of feathers like the *upupa* or *hopoe*; its beak is as ftrong as iron, and in the building feafon it cuts its way with this into the firmeft part of trees, and builds its nefts in the holes it makes in this manner; it is of the fize of a common hen, and is of a very beautiful green colour, fometimes variegated with other colours, fometimes plain. This is the defcription Father Camelli gives of this bird, and it feems very plainly to be a fpecies of *woodpecker* of a very large and beautiful kind. They have got an opinion there, that if the opening into this creature's neft be ftopped up with a large iron pin, the bird knows a plant which has the effect of foftening iron; and that it procures this plant, and applying it to the iron foon makes its way in. A ftory fomething like this the common people of England alfo have of the *woodpecker*.

PALALIA, in botany, a name ufed by fome authors for the *cyclamen* or *fowbread*. *Ger.* Emac. Ind. 2. See CYCLAMEN.

PALAPARIJA, in zoology, the name of a fpecies of Eaft India ferpent, found in the ifland of Ceylon. It is a large kind, and beautifully variegated in colour, with a great deal of red about it. It is one of thofe fpecies which naturally live under ground. *Ray*'s Syn. Anim. p. 33.

PALARIA, among the Romans, a kind of excercife performed at a ftake by the foldiers.

The ftake being fixed immoveable in the ground, and fix feet high above it, the young undifciplined foldiers advanced againft it armed with a hurdle and cudgel, inftead of a fhield and fword, and went through all the rules of attack and defence, as if actually engaged with an adverfary. Sometimes they ftood at a diftance, and attacked it with miffive weapons, at the fame time ufing all the requifite motions for defending themfelves, and warding off what might be thrown againft them. *Pitifc.* Lex. Ant. in voc.

PALATE (*Cycl.*)—Wounds of the *palate* and other parts of the mouth are only to be healed by being anointed with honey of rofes, either alone or mixed with balfam of Peru, or with oil of myrrh *per deliquium*. *Heifter*'s Surg. 81.

Bones of the PALATE. There are two bones fituated in the pofterior part of the arch of the *palate*, between the *pterygoide apophyfis* and the *offa maxillaria*, and running up on the fides of the *nafal foffæ* all the way to the bottom of each orbit. The figure of thefe bones is not fquare, as has been faid by thofe who have only feen that portion of them which belongs to the *palate*, and from thence have named them *offa palati*. The entire bone is crooked, hooked, pointed and uneven, tho' of a fmall fize. Each of thefe may be divided into four portions, one fuperior, one middle, and two lower; whereof one is the anterior, the other the pofterior.

The lower and anterior portion, to be called properly the *portio palatina*, is the bafis or body of the bone, and the only part of it which the antient anatomifts, except Vidus Vidius, have obferved. It completes the arch of the *palate*, and the bottom of the *nafal foffa*; the inner edge of it is raifed, and that, joined to the like edge of the other bone, forms a groove which receives part of the *feptum narium*, in the fame manner as the other part of it is received in a like groove of the *offa maxillaria*. The pofterior edge is gently floped, and ends inward in a point, which joins a like point in the other bone.

The lower and pofterior portion, to be called properly the *pterygoide*, is pointed and hollowed on each fide, to join the *pterygoide apophyfis*, of which it completes the *foffa*, being fixed like a wedge in the irregular notch of that procefs. Exteriorly it is uneven, the better to be connected with the *os maxillare*. This portion is diftinguifhed from the *portio palatina*, and alfo from the middle portion, by an oblique half canal, which with the half canal in the maxillary tubercle, forms an entire canal, the lower end of which is the pofterior *foramen palatinum*.

The middle portion, properly to be called the *nafal*, is very thin, and is fituated laterally. The internal fide of it is a little concave, the outfide a little convex; the concavity is turned toward the nares, and at the lower part of it there is a tranfverfe eminence or bony line, which diftinguifhes this portion from the *portio palatina*. The convex outfide partly covers the opening of the maxillary lines. At the lower part of it is a tranfverfe groove, anfwering to the eminence on the other fide, and moulded, as it were, by the tranfverfe exterior eminence of the *os maxillare*.

The upper portion, properly called the *orbitary portion*, is diftinguifhed from the *nafal portion* by a notch, which, together with the *pterygoide apophyfis* of the fpheroidal bone, forms an opening more or lefs confiderable, which may be called the *foramen fpheno-palatinum*, or *pterygo-palatinum*. This portion has five little fides, three of which are rather cavities. One fuperior, which completes the extremity of the bottom of the orbit, and is more or lefs flat, very fmall, fmooth, and triangular. One anterior, which is a little hollow, covering the upper part of the maxillary tubercle, and by a fmooth raifed edge compleating the *fiffura fpheno-maxillaris*. The third fide is likewife anterior, more hollow than the former, and joins the back part of the labyrinth of the *os ethmoides*. The fourth is pofterior, and more or lefs hollow, anfwering to the fphenoidal *finus*. The fifth is lateral and external, covering the pofterior and upper part of the maxillary *finus*. Thefe fides and cavities, however, fometimes vary; being in fome fubjects found fingle, in others complex: there is very little diploe in thefe bones, except in the *palatine* and *pterygoide* portions. They are joined to each other by the *portio palatina*; to the vomer by the common groove, formed by their raifed edges; to the maxillary bones before and laterally; and behind to the fphenoidal bone; to the inferior fhells of the nares by their tranfverfe eminences; and laftly, by their orbitary portions, to the *os ethmoides*. *offa maxillaria*, and *os fphenoides*. They complete the arch of the *palate*, the *pterygoide* and *nafal foffæ*, and the orbit. They affift alfo in fupporting the vomer and the *conchæ narium inferiores*. *Winflow*'s Anatomy, p. 37.

PALATO-*ftaphylinus*, in anatomy, a name given by Douglafs to the mufcle called by Morgagni *columellæ mufculus teres*, and by Albinus and fome others, the *azygos uvulæ*, and by fome the *epiftaphylinus*.

PALINCOTOS, a term ufed by Hippocrates to exprefs fuch difeafes as are wont to return with all their violence upon the patient, after their feeming to have left him, whether for a longer or a fhorter period of time.

PALINDROMIA, a term ufed by Hippocrates and many other writers to exprefs a preternatural running of the peccant matter of difeafes to the more noble parts.

PALINGENESIA, is ufed among chemifts for the reproducing a mixed body from its afhes.

This has been pretended to by many, as well as the philofopher's ftone and other wonderful powers; but as to the *palingenefia*, or refufcitation of plants, the inftances produced are no more than fome of thofe artificial vegetations which the learned Monf Homberg has obferved and defcribed many times. See *Homberg* in Mem. Acad. Sciences, 1710; and *Boyle*'s works abridg. Vol. I. p. 69.

PALINGMAN, in our old ftatutes, feems to be a merchant-denizen, one born within the Englifh pale. Stat. 22. Ed. IV. c. 23. and 11 H. VII. c. 22. *Blount*, *Cowel*.

PALINIDRYSIS, a word ufed by Hippocrates to exprefs the fubfiding of a tumour by the difperfion of the matter that occafioned it without its breaking.

PALIRRHŒA, a word ufed by the old Greek authors to exprefs the reflux or retrograde courfe of the humours, as in cafes of the cholera morbus, where people vomit up their ftools.

PALIURUS, *Chrift-thorn*, in botany, the name of a genus of trees, the characters of which are thefe: the flower is of the rofaceous kind, and is compofed of feveral petals arranged in a circular form; from the cup of the flower there arifes a

piftil,

pistil, which finally becomes a clypeiform or shield-like fruit, containing a roundish stone, divided into three cells, in which there are three roundish kernels. *Tourn.* Inst. p. 616.

There is only one known species of the *paliurus*, which is the common *Christ-thorn*.

PALLAS, in astronomy, a name given by some to the first satellite of Jupiter. *Lowthorp*'s Abr. Phil. Transf. Vol. I. p. 407.

PALLAX, a name given by some of the affected chemical writers to an imaginary factitious stone, composed of the heaven and earth, of the moon or silver, with an equal weight of the sun or gold. This is their own explication of it.

PALLET (*Cycl.*)—PALLET, in ship-building, is a room within the hold, closely parted from it, in which, by laying some pigs of lead, &c. a ship may be sufficiently ballasted, without losing room in the hold; which, therefore, will serve for stowing the more goods.

PALLIUM (*Cycl.*)—PALLIUM-*ducale*, in natural history, a name given by writers on shells to a kind of *pecten* or *scallop*, of a large size and beautiful appearance, tho' simple colour: there are two species of this, a red and a yellow one. See the article PECTEN.

PALLIUM-*purpureum*, a name given by Basil Valentine, and others of the affected writers in chemistry, to a powder of a purple colour, prepared from gold. It is made by preparing an amalgama of gold and mercury, and after the mercury is driven off by the retort, the remaining matter is mixed with sulphur, and calcined by a well regulated fire till reduced to a purple powder. This is called also the *solar powder*, and has, like the other preparations of this metal, many imaginary virtues ascribed to it.

PALMETTO-*royal*, a name given by Ligon to a tree of the palm kind. Its trunk is very tall and streight, and hollowed regularly in the center; yet so tough, that it is never blown down, nor destroyed by storms. It is recommended for the making long telescopes for celestial observations.

PALM (*Cycl.*)—The famous cabbage-tree of Barbadoes is a kind of *palm*: it grows to the height of three hundred feet, and tho' the sprouts of one year's growth are so tender, that they are eaten as cabages, yet the tree itself is one of the most durable woods we are acquainted with, and will not rot on any account, but is so firm, that it is scarce possible to make a nail enter it. Phil. Transf. N. 36.

PALM-*tree*. The several species of this tree may be all raised with us from the seeds, which must be sown in pots of light earth, and plunged into a bark hot-bed. When the young plants come up, they must be transplanted into single pots, and preserved in the stove. The soil th y succeed best in is made of one third pasture land, one third sea sand, and the other third rotten tanner's bark, or rotten horse-dung; and they must be planted in pots, in proportion to their size, but these should not be too large. They will require to be removed once a year, but this must be done with great care. *Miller*'s Gard. Dict.

PALMARIS *cutaneus*, a muscle commonly known by the name of the *palmaris brevis*. It is a small thin plane of fleshy fibres, situated transversely, or more or less obliquely, under the skin of the large eminence in the palm of the hand, between the carpus and the little finger; its fibres adhering to the skin, and being in some measure interwoven with the *membrana adiposa*. These fibres are fixed along the edge of the *aponeurosis palmaris*, from the large ligament of the *carpus* toward the little finger: and they run in for some space on the plane of the *aponeurosis*, but without any connection with the bones of the *metacarpus*. Near the *aponeurosis* these fibres are more or less tendinous, and some of them often cross each other. They are sometimes so thin and pale, as hardly to be sensible; and in some subjects the muscle seems to be divided into several parts. *Winslow*'s Anatomy, p. 193.

It is a doubt with some authors whether the *palmaris cutaneus* or *brevis* be a distinct muscle. Fallopius calls it, *caro quædam quæ musculorum effigiem habet*; a portion of flesh which has the appearance of a muscle. And Douglass calls it, *caro quadrata*; a square portion of flesh: tho' he adds the name *palmaris brevis*, given it, on its supposition of being a muscle, by another author.

PALMATED-*roots*, are tuberose-roots of a flattish shape, and divided into several oblong and slender branches, resembling so many fingers. Of this sort are the roots of some of the orchis kind, called hence *palmated*.

PALMATED-*leaf*, among botanists. See LEAF.

PALMATED-*stone*, *palmati-lapides*, in natural history, a name given by the antients to a sort of stones which were always found of the shape of a hand with its fingers. They were frequent in Spain, and some which were found of a fine black were reputed to be a kind of marble. The greater number were white, and were composed of the matter of one of the softer and less beautiful quarry-stones.

PALMIPEDES, *web-footed*, in zoology, the name of a genus of birds living about waters, and furnished by nature with feet for swimming. The general characters of these birds are these: they have all short legs, excepting only three, the *flamingo*, *corrira*, and *avosetta*, which are singular and of a peculiar genus. Their thighs are feathered to the joint; their hinder toes, if any, are short; their rumps are less prominent than in other birds; and they have in general broad beaks, and have an appendage on the extremity of their upper chap. *Ray*'s ornithology, p. 241.

PALMIPES, among the Romans, a long measure, containing a foot and a *palm*, or five *palms*; and was less than the cubit by one *palm*. *Pitisc* in voc.

PALMITES, in botany, a name given by some authors to the *palma humilis*, or *dwarf palm*, called by others *chamærops*. Gen. Herb. 1335.

PALPÆBRA (*Cycl.*)—PALPEBRÆ *superioris primus*, in anatomy, a name given by Cosserius and some others to one of the muscles of the face, whose office it is to lift up the upper eye-lid, and by that means open the eye: it is hence called by Cowper and Douglass, *aperiens palpebram*; by some, *aperiens oculum*; and by Albinus, the *levator palpebræ superioris*. See APERIENS, *Cycl.*

PALPITATION *of the heart*, (*Cycl.*) a term used by medical writers to express a spastic contraction of the heart, when it leaps and beats violently at different intervals.

This is sometimes idiopathic, or a disease in itself, and attendant on no other; but that rarely happens, and it is usually symptomatic, and merely an attendant on other disorders. In general we are to distinguish a *palpitation of the heart* thus considered as a disease, or at least as a symptom of one, from those commotions of the heart which we occasionally bring on by running or any other violent exercise, which throw the blood into commotions.

Signs of it. The evident and obvious symptom of this complaint, is the vehement pulsation of the heart against the solid parts of the breast, which is often so great, that it may be seen or even heard by the persons who stand by. To this there are usually joined an anxiety of the *præcordia*, which throws the person into a sweat, a languor and lassitude of the limbs in general, a paleness of the face, a difficulty of respiration and cardialgia, with frequent faintings; and finally, there is usually a costiveness and flatulences of the abdomen attending on it.

Persons subject to it. It is a complaint that chiefly affects persons of sedentary lives, and of a plethoric habit of body Scorbutic, hysteric, and hypochondriac persons are also frequently subject to it; and such as have obstructions of the menses. Those people who have been used to regular bleedings, and have afterwards neglected them, are also subject to this complaint; and those who are subject to sudden passions, and frequently suppress them. Sleeping in the open fields has also been known to bring it on; and persons of a melancholic habit are usually more than others subject to it. Young women, whose menses have not appeared, or who have had them suppressed by some accident, and in whom nature is labouring to bring them on again, are also very subject to violent *palpitations*; and such as have acute or intermittent fevers coming upon them. Persons of plethoric habits are often seized with *palpitations of the heart* in their sleep, and when they wake they feel them for some minutes afterwards. Finally, persons who have polypuses of the heart are always grievously afflicted with *palpitations* attended with difficulties of breathing.

Causes of it. Besides what has been already observed, it is to be remarked, that the passions of the mind very frequently occasion this disorder; thus, sudden terror, fear, a suppression of anger, and the like, will at any time bring on a *palpitation*, without any other cause A high diet and ease, with a sedentary life, also often occasion them; and in young people, not arrived at puberty, they are often found to be occasioned by worms in the intestines

Prognostics in it. The beginnings of complaints of this kind, and slighter cases, when they continue so, are attended with no great danger; but when the disorder grows into a habit, it is not only very troublesome, but very dangerous. When more causes than one conspire to produce it, it is not only more violent, but the patient is more subject also to relapses; and in the end, inflammations, spittings of blood, polypuses of the heart, and infarctions of the viscera come on: not unfrequently also are left fevers, which become dangerous. Sometimes also convulsions and other affections of a like kind, even palsies are brought on by these disorders. Finally, when an habitual *palpitation of the heart* has been brought on by terror alone, it always proves very difficult of cure, whatever means are used.

Method of cure. The primæ viæ must be first cleansed by infusions of rhubarb and sena, and other gentle purges: after this it is proper to bleed in the foot; but it is to be observed, that if the orifice be not large, nor the blood taken away in sufficient quantity, it is of not the least effect in this case. After this the blood is to be attenuated by drinking plentifully of warm and weak liquors, and by moderate exercise. After this, some of the gentle alexipharmics are to be given, and the spring juices of brook-lime, water-cress, and the like. Finally, there are to be given such things as promote an equal distribution of the blood and humors: mixtures of volatiles and alcalies, as of spirit of hartshorn and tincture of salt of tartar, and gentle anodynes, if necessary. Besides these, clysters will often do great good, as will also the frequent washing

ing the feet with warm water, and the hanging camphor near the part, and ſpirit of caſtor, ſaffron, and the like, do well to be rubbed on the breaſt.

Bleeding muſt never be omitted in this caſe, for without it no medicines will be able to take effect. In caſes when a hypochondriac habit conſpires in the cauſe of this complaint, the attemperating powders of nitre, cinnabar, and the like, always prove of very great ſervice. In caſes of a chloroſis with this complaint, bitters and chalybeates uſually prove a remedy; and when a ſuppreſſion of the menſes, or hæmorrhoids is the cauſe, the bringing them to their priſtine regular ſtate is a cure. It is never proper to allay the motion till the plethora, which occaſions it is removed, unleſs in caſes of its coming on merely by the paſſions, without any antecedent cauſe in the blood; in this caſe, gentle opiates may be given without danger. Steel medicines and the volatile ſalts, when they are given in an imprudent manner, always make the diſeaſe worſe, inſtead of doing any thing toward a cure. Finally, a change of a ſedentary life, into a moderately active one, will do more than any medicines. *Junck.* Conſp. Med. p 626, ſeq.

Monſieur de la Hire was cured of a chronical *palpitation* of the heart, by a quartan ague. See *Fontenelle*, in his Eloge.

PALSY (*Cycl*) — Among other remarkable caſes of this terrible diſeaſe, we have, in the philoſophical tranſactions, one of a periodical *palſy*. The author quotes two inſtances of a like kind, by way of countenance to that which he relates. The German Ephemerides mention a young paralytic man who ſpoke only one hour in every four-and-twenty, and that always at a regular time, beginning between twelve and one at noon every day, and his power of ſpeech ceaſing always between one and two: this continued twelve years upon him. The other caſe is not recorded in books, tho' well atteſted.

The caſe in the tranſactions, is of a ruddy ſanguine young woman who fell into a *palſy*, in which ſhe loſt her voice and the uſe of her legs. This was at firſt carried off by medicines, but afterwards returning again at times, at length became regularly periodical, ſeizing her on the Tueſday of every week, and going off again on the Friday. This courſe it obſerved very regularly for the firſt year, except twice.

After this, on taking proper medicines for ſome conſiderable ſpace of time, ſhe became ſo well, that her fits laſted only a day and a half, coming on always on a Tueſday morning, and going off again on a Wedneſday. In this manner ſhe continued to have them ſeveral months, but ſhe was at length perfectly recovered. Phil. Tranſ. N° 242. p. 60.

This diſtemper, according to Dr. Cheyne, may be cured by a total cow-milk diet. He thinks the medicines commonly preſcribed in ſuch caſes may retard the progreſs of the diſtemper, but that it is never to be eradicated if the ſtroke be deep, or life far ſpent, but by cow-milk only. See Nat. Method of curing, p. 265.

Mr. Boyle gives an account of an *hemiplegia*, or *palſy* of one ſide, occaſioned by a ſmall ſplinter of a bone preſſing on the dura mater. The patient in leſs than five hours after the bone was taken out, found himſelf able to move his finger, and within two or three days to lift his arm, which had been reduced to ſkin and bone, but ſoon recovered its proper ſize. Works Abr. Vol. 1. p. 37.

Hofman diſtinguiſhes *palſies* into ſerous and ſanguineous. In the firſt kind, raiſing an artificial fever by hot, acrid, nervous, and volatile medicines, by ſtrong exerciſe, and hot bathing, often effects a cure. But in the ſanguineous kind, accompanied with febrile motions, ſuch remedies ought not to be applied. Oper. T. 3. p. 198. §. 26.

There is a kind of *palſy* called *beriberii*, to which the natives of the Eaſt Indies are peculiarly ſubject.

The word in the Indian language ſignifies a ſheep; and Bontius ſuppoſes it was attributed to this diſeaſe, becauſe the perſons afflicted with it thruſt out their knees, and lift up their legs ſo much in walking, as in ſome ſort to imitate the gate of ſheep. It is a kind of tremor, or *palſy*, in which the uſe of the hands and feet are in a great meaſure taken away; and ſometimes it extends itſelf to the whole body.

The principal cauſe of this diſeaſe is ſaid to be a thick viſcous humor, which in the night ſeaſon, eſpecially in the rainy time, which holds inceſſantly from November to May, falls upon the nerves, while people fatigued with the heat of the day, throw aſide their cloaths and ſleep without any covering; by which means the phlegmatic humor which before generated principally in the brain, eaſily ſeizes upon the nerves; for the nights in theſe countries, compared to the days, are very cold The conſequence of this is, that the joints become lengthened, the pituitous humors inſinuating themſelves between the junctures, ſo as to relax the nerves and ligaments. Tho' this diſeaſe for the moſt part comes on very gradually, and by ſlow advances, yet ſometimes it ſeizes a perſon all at once, as when any one being very much fatigued and hot, drinks a vaſt quantity of any cold liquor. And thus we ſee, even in our own country, that when any one has been violently heated by exerciſe, and drinks an immoderate quantity of a cold liquor, it often throws him into the utmoſt hazard of his life.

The ſymptoms of this diſeaſe are always manifeſt, even to the ſight. There is ever an univerſal laſſitude of the whole body. All motion, but particularly that of the hands and feet, becomes vitiated and depraved; and the ſame ſort of throbbing and titillation is felt as we feel in our fingers and toes in cold weather, only the pain is leſs acute; and ſometimes the voice is ſo far affected, that the patient can ſcarce ſpeak articulately.

Bontius himſelf was once afflicted with this diſtemper, while in the Eaſt Indies, and had this particular ſymptom of it in ſo great a degree, that for a whole month thoſe who ſat cloſe by him could not, without great difficulty, hear what he ſaid. Theſe are the common ſymptoms of the diſeaſe; but beſide theſe, it is at times attended with all thoſe others which may be ſuppoſed to ariſe from a cold cauſe.

The cure is uſually very tedious; for theſe cold humors are very ſlowly, and with difficulty diſcuſſed. The diſeaſe is not naturally mortal, however, unleſs it affects the breaſt; in which caſe it ſometimes wholly ſtops the breath. In order to a cure, the patient is of all things to avoid confining himſelf to his bed; walking, riding, and all ſorts of exerciſe are uſeful; ſtrong and ſmart frictions are alſo very uſeful, and the Bengal ſervants are uſed to theſe, and are very dextrous in the uſe of them.

There is alſo great relief had from fomentations made of decoctions of the herb *lagondi*, which has all the virtues of our chamæmile and melilot, but in a much greater degree. The leaf of this plant is like that of our perſicaria or arſmart; and its ſmell very aromatic The hands and feet are alſo to be anointed with oil of cloves, or mace mixed with oil of roſes. But more than all theſe, there is relief found in a kind of naphtha, which is very common in Sumatra, and is called *miniac tarnoh*, or *oil of the earth*. This is of a ſtrong, but not very nauſeous ſmell, and is ſo great a remedy, that being rubbed on the hands and legs, it is always an almoſt immediate relief. The Barbarians know as well as we the value of this precious balſam; and the king of Achin, who is the moſt powerful prince in that iſland, has forbidden its exportation, under the pain of death; ſo that the inhabitants can only bring it off by ſtealth in the dead of the night, to the Dutch and Engliſh ſhips which happen to lie in the way.

Theſe are the things which give temporary relief; but as the diſeaſe is of the chronic kind, the cure is to be performed by long courſes of the decoctions of the roots of China, and ſarſaparilla, and guaiacum wood, which by their gentle heat diſcuſs the cold humors which are the root of the diſeaſe, and carry them off by perſpiration or urine. Purging at proper intervals is alſo highly neceſſary; and the cathartics moſt in uſe there in this caſe, are, aloes and gamboge. Bleeding is by all means to be forbid; and the relicks of the diſeaſe are uſually very happily carried off by Venice treacle, and other ſudorific and nervous medicines, and gentle exerciſe is the beſt remedy to prevent its return. *Bontius* de Medicina Ind.

PALUM *ſanctum*, in botany, a name by which ſome authors have called a ſpecies of the *guaicum tree*, called the *lignum ſanctum*, or *holywood*. *Park.* Theatr. p. 1587.

PALUMBARIUS *accipiter*, the *goſhawk*, a ſpecies of hawk of the ſhort-winged kind It is larger than the common buzzard, and is brown on the back, and very white on the belly, with tranſverſe ſtreaks of browniſh black; theſe are of an undulated figure, and laid very near one another. Its legs and feet are yellow, and its beak black, with a yellow membrane covering its baſe Its wings, when cloſed, do not nearly reach to the end of its tail; by which, and by its ſize it is eaſily diſtinguiſhed from all other hawks. Its tail is long and of a browniſh grey, with three or four tranſverſe ſtreaks on it, placed very diſtant from one another. It will ſeize on pheaſants, geeſe, and even hares, but its moſt common prey is the partridge. *Ray*'s Ornithology, p. 51.

PALUMBES, the *ring-dove*, in zoology. See RING-*dove*.

PAMBŒOTIA, Παμβοιωτια, in antiquity, a feſtival celebrated by all the Bœotians who aſſembled near Coronea, at the temple of Minerva, ſurnamed Itonia. *Potter*, Archæol.Græc. l. 2. c 20. T. 1. p. 419.

PAMMACHION, Παμμαχιον, a name by which the exerciſe *pancratium* is ſometimes called, whence the combatants were likewiſe called *pammachi*, Παμμαχοι. *Potter*, Archæol. Græc. l. 2. c. 22. T. 1. p. 444.

PAMUCHLEN, in zoology, a name by which ſome call the ſpecies of *cod-fiſh*, commonly named by authors *aſellus ſtriatus*. *Willughby*'s Hiſt. Piſc. p. 172.

PANACIA, Πανακεια, in antiquity, a feſtival in honour of Panace. *Potter*, T. 1. p 422.

PANALETHES, a name uſed by many authors for a plaiſter ſuppoſed to be of the greateſt virtues. It is deſcribed by Aëtius. Tetrabib. 4. Serm. 3. cap. 2.

PANAMA-*ſhell*, a ſpecies of *dolium*. See DOLIUM.

PANARITIUM, a word uſed by ſome authors to expreſs a *whitlow*, or *paronychia*.

PANCALA-*aurea*, a name of a famous antidote, compoſed of many ingredients, deſcribed by Myrepſus.

PANCARPIA, the name of a ſort of cake much uſed at Alexandria,

andria, and usually covered with paper for the sake of its keeping the longer.

PANCH, or PANTCH, in the sea language. See PAUNCH.

PANCHRESTARII, among the Romans, those who prepared the *pancrest*, or *universal remedy*. *Pitisc.* in voc. See the article PANCHREST, *Cycl.*

PANCHRUS, the name given by some of the antient writers on natural history to a gem which they say has all colours: probably the opal.

PANCLADIA, Παγκλαδια, in antiquity, a festival celebrated by the Rhodians when they pruned their vines. *Potter*, Archæol. Græc. T. 1. p. 419.

PANCRASIUM, in the materia medica, a name used by some authors for the *squill*, of the root of which the oxymell of squills is made. *Park.* Parad. p. 133.

PANCRATIASTES, in antiquity, a combatant in the exercise called *pancratium*. *Potter*, Archæol. Græc. T. 1. p. 444. See PANCRATIUM, *Cycl.*

PANCRATIASTES was also applied to one who had gained the victory in all the kinds of exercise used in the *pancratium*. *Pitisc.* in voc. See PANCRATIUM, *Cycl.*

PANDEMON, Πανδημον, in antiquity, the same with the festival Chalceia and Athenæa. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 422.

It was so called from the great concourse of people that used to meet at this solemnity. See CHALCEIA and ATHENÆA.

PANDIA, Πανδια, in antiquity, an Athenian festival in honour of Jupiter. For the origin of this solemnity, see *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 422.

PANDROSOS, Πανδροσος, in antiquity, an Athenian festival in memory of *Pandrosus* the daughter of king Cycrops. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1 p. 423.

PANDURIFORM-*leaf*, among botanists. See LEAF.

PANDYSIA, Πανδυσια, in antiquity, public rejoicings when the season through its coldness and intemperance forced the sailors to stay at home. *Potter*, T. 1. p. 423.

PANEGYRIS, Πανηγυρις, among the Greeks, a fair, or festival day, on which the people used to meet together. It exactly corresponded to the Nundinæ of the Romans. *Pitisc.* in voc. See NUNDINÆ.

PANELLENIA, Πανελληνια, in antiquity, a public festival celebrated by an assembly of people from all parts of Greece. *Potter*, Archæol. Græc. T. 1. p. 423.

PANEMUS, in chronology, the Bœotian name of the Athenian month *metagitnion*, which was the second of their year, and answered to the latter part of our July and beginning of August. See METAGITNION and MONTH.

PANEROS, the name of a beautiful stone dedicated to Venus. It was called also by some *pausebastos*, and was probably one of the beautiful agates.

PANGONIA, in natural history, the name of a genus of crystal. See Tab. of Fossils, Class 3.

The word is derived from the Greek πᾶς, numerous, and γόνυ, an angle, or bending, and expresses a crystal, composed of many angles.

The bodies of this genus are single-pointed, or imperfect crystals, composed of dodecangular or twelve-planed columns, terminated by twelve-planed pyramids, and the whole body, therefore, made up of twenty four planes.

Of this genus there are only three known species: 1. A brownish-white one, with a long pyramid. This is found in Silesia and Bohemia; sometimes in mountains, and sometimes on the sides of rivers, and is esteemed a very valuable crystal. 2. A yellowish-brown one, with a short pyramid. This is often brought over to us under the name of *Saxon topaz*, among the other crystals commonly known by that name. And 3. A clear colourless one, with a very short pyramid. This is a very valuable crystal, and is produced in the East Indies, being often brought over among the Indian ballast. *Hill's* Hist. of Foss. p. 187.

PANICASTRELLA, in botany, the name by which Micheli has called a genus of plants named by Linnæus *cenchrus*. See the article CENCHRUS.

PANICUM, in the Linnæan system of botany, the name of a distinct genus of plants, of the grass kind, the distinguishing characters of which are, that the calyx is composed of several leaves, and contains only one flower; the leaves of it are capillary and unequal in their insertions. The glume is made of two valves, and contains only one flower: the valves are oval and pointed, and are both small, but one more so than the other. The flower is also composed of two valves, both oval and pointed, but the one smaller and flatter than the other. The stamina are three short capillary filaments. The antheræ are oblong. The germen of the pistil is roundish; the styles are capillary and two in number, and the stigmata are feathered. The flower surrounds and incloses the seed, and never opens to drop it out. The seed is single and roundish, but something flatted. *Linnæi*, Genera Plantatum, p 17.

PANIONIA, Πανιωνια, in antiquity, a festival in honour of Neptune, celebrated by a concourse of people from all the cities of Ionia.

One thing is remarkable in this festival, that if the bull offered in sacrifice happened to bellow, it was accounted an omen of the divine favour; because that sound was thought to be acceptable to Neptune. *Potter*, Archæol. Græc. T. 1. p. 423.

PANIS-*dæmonum*, in natural history, a name given by authors to a sort of coarse stone, common in Sweden, and some other places, and usually found in roundish, but somewhat flatted masses, resembling a loaf in form.

PANNEL, in the Scotch law, denotes the prisoner at the bar, or person who takes his trial before the court of justiciary, for some crime.

PANNONICA-*bolus*, in the materia medica, a name by which Kentman, and some others, have called the earth more usually known by the name of *bolus toccaviensis*. *Kentman's* Nomenclator Foss p. 7. See the article TOCCAVIENSIS.

PANOCHIÆ, a name by which some chirurgical authors call *bubos* in the groin.

PANOMPHÆUS, Πανομφαιος, in antiquity, a designation given to Jupiter, because he was looked upon as the original author of all sorts of divination, having the books of fate, and out of them revealing either more or less, as he pleased, to inferior dæmons. *Potter*, T. 1. p. 263.

PANOPSIA, Πανοψια, in antiquity. See PYANEPSIA, *Cycl.*

PANSAPAN, in botany, a name by which some authors have called the tree whose wood is the logwood, used in dying, and in medicine. *Herm.* Mus. p. 42.

PANTARBE, in natural history, a name given by authors to an imaginary stone, the virtues of which were similar to those of the magnet; but exerted upon gold as those of the loadstone upon iron. The antients as well as later writers, seem to have all had an opinion, that there was such a stone as this, and the *amphitane* of Pliny is described as possessing this remarkable quality; but neither they nor we, ever found reason from any experiment to believe, that there was any such stone.

PANTER, in the sea language. See SHANK-PANTER.

PANTHERA, in zoology, a name by which many have called the *leopard*, more properly called *pardalis*. See PARDALIS.

PANTHERA-*lapis*, in natural history, the name of a species of stone found in Egypt, and the East Indies, and described to be of a yellowish colour, variegated with dusky spots of the colour of those on the skin of the panther. The writers of the middle ages have attributed many absurd properties to it: it seems to have been a species of agate.

PANTHERINE *tables*, *pantherinæ mensæ*, among the Romans, tables made of citron wood, which were held in such high esteem, as to equal the value not only of silver and gold, but likewise of pearls. They had this name from their being spotted after the manner of panthers. *Hofm.* Lex. in voc.

PANTICES, a word used by some medical writers to express the intestines.

PANTOMIME, Παντομιμος, among the antients, a person who could imitate all kinds of actions and characters by signs and gestures, without speaking.

The *pantomimes* made a part in the theatrical entertainments of the antients; their chief employment was to express in gestures and action, whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied. They were very antient in Greece, being derived from the heroic times, according to some; but however this may be, they were certainly known in Plato's time. In Rome it was so late as the time of Augustus before they made their appearance. As to their dress, it was various, being always suited as near as possible to that of the person they were to imitate. The crocota was much used among the Roman *pantomimes*, in which and other female dresses they personated women. *Pitisc.* in voc. See MIME, *Cycl*

PANTON-*shoe*, in the manege, a horse-shoe contrived for receiving narrow and hoof-bound heels. Its spunges are much thicker on the inside than on the outside; so that the part which rests upon the horn or hoof, runs slope-wise to the end, that the thickness of the inside of the shoe may bear up the heel, and throw or push it to the outside.

Panton-shoes are likewise proper for horses that have false quarters.

PAPAN, in natural history, the name given by the inhabitants of the Philippine islands, to a species of duck common in their lakes and marshes. This is very large and beautiful, and is called by Father Camelli *anas regia*, or the *royal duck*: it is not so common, however, as a little kind which they call *salagasir*; this is not larger than a man's fist. See SALAGASIR.

PAPAVER, *poppy*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the rosaceous kind, consisting usually of four leaves, disposed in a circular form. The cup is composed of two leaves, and from it there arises a pistil, which finally becomes a seed vessel, of a sort of oval oblong figure, and adorned with a head or covering; under which, in many species, there are a chain of apertures. Within the head or fruit, there are numerous lamellæ, to which the seeds adhere in the manner of placentæ. The seeds are usually small, and of a roundish figure See Tab. 1. of Botany, Class 6.

The species of *poppy*, enumerated by Mr. Tournefort, are these: 1. The white *poppy*, or garden *poppy*, with white seeds.

2. The

2. The white-feeded garden *poppy*, with pale purple flowers. 3. The garden white-feeded *poppy*, with greyifh flowers with purple bottoms to the petals. 4. The garden *poppy*, with flowers of a fair white, variegated with red, and with yellow feeds. 5. The garden *poppy*, with black feeds; the wild *poppy* of Diofcorides, and black *poppy* of other authors. 6. The garden *poppy*, with double flowers of a deep violet colour. 7. The garden *poppy*, with double flowers of a pale violet colour. 8. The hoary-feeded *poppy*, with apertures in the heads. 9. The red-flowered *poppy*, with brown feeds. 10. The crefted *poppy*, with white flowers and white feeds. 11. The crefted *poppy*, with red flowers and black feeds. 12. The crefted *poppy*, with variegated red and white flowers. 13. The fingle flowered crefted *poppy*, with purple petals with bluifh grey bottoms. 14. The double flefh coloured garden *poppy*. 15. The double purple *poppy*. 16. The double bright red *poppy*. 17. The double filver white *poppy*. 18 The double white *poppy*, with red edges 19. The fnow-white double *poppy*. 20. The double deep purple *poppy*. 21. The blood-red double *poppy*. 22. The violet coloured double *poppy*. 23. The fmall white many flowered *poppy*. 24. The double flowered black *poppy*. 25. The double *poppy*, with variegated and jagged flowers. 26. The jagged flowered *poppy*, with bluifh and whitifh bottoms to the leaves. 27. The common wild red *poppy*. 28. The greater wild red *poppy*, with variegated flowers. 29. The common wild corn *poppy*, with white flowers. 30. The red corn *poppy*, with white bottoms to the petals. 31. The wild corn *poppy*, with flefh-coloured flowers. 32. The double flowered corn *poppy*. 33. The corn *poppy*, with a double red lead coloured flower. 34. The corn *poppy*, with double fiery red flowers. 35. The double corn *poppy*, with fiery red flowers with white edges to the petals. 36. The double purple flowered corn *poppy*. 37. The double red corn *poppy*, with white bottoms to the leaves. 38. The common fmaller corn *poppy* 39. The corn *poppy*, with oblong hairy heads. 40. The longer hairy-headed corn *poppy*. 41. The very long fmooth headed corn *poppy*. 42. The corn *poppy*, with undivided leaves. 43. The yellow flowered pyrenæan *poppy*. 44 The coriander-leaved alpine rock *poppy*. *Tourn.* Inft. p 237. feq.

PAPAYA, in botany, the name of a genus of plants, the characters of which are thefe: the flowers are of two kinds; the one fort is tubulated and divided into fegments, like the rays of a ftar, at the end: the flowers of this kind are the barren or male ones. The others are of the rofaceous kind, being compofed of feveral petals arranged in a circular form; from the cup of thefe flowers there arifes a piftil, which finally becomes a flefhy fruit, of the fhape of a melon, containing ftriated feeds covered with hufks.

The fpecies of the *papaya* enumerated by Mr. *Tournefort*, are thefe: 1. The *papaya* tree, with a fruit like the melopepo, or melon pompion, called the platanus-leaved *papaya*, and by fome the male mamolla. 2. The *papaya*, with very large fruit, of the fhape of the pompion 3. The *papaya* with oblong or melon-fhaped fruit. *Tourn.* Inft. p. 659.

PAPER (*Cycl.*)—Mr. Boyle tells us, that *paper*, befides its common ufes, may be made into frames for pictures, fine embofled work, and other parts of furniture. For this purpofe, a convenient quantity of the beft white fort may be fteeped for two or three days in water, till it becomes very foft; then reducing it by the mortar and hot water into a thin pulp, it is laid on a fieve to draw off its fuperfluous moifture; then putting it into warm water, wherein a confiderable quantity of frefh glue, or common fize, has been diffolved, it may afterwards be put into moulds to acquire the defigned figure; and when taken out may be ftrengthened, as occafion requires, with plaifter or moiftened chalk, and, when dry, painted or overlaid. *Boyle*'s works abr. Vol. I p. 149.

Another ufe of *paper* is to ftop up cracks or fiffures in wooden veffels, to hold water; for, in this cafe, it will forcibly dilate, and fill the place wherein it is to lodge.

PAPER-*office*, an antient office within the palace of Whitehall, wherein all the public papers, writings, matters of ftate and council, letters, intelligences, negotiations of the king's minifters abroad, and generally all the papers and difpatches that pafs through the offices of the two principal fecretaries of ftate, are lodged and tranfmitted, and there remain difpofed in the way of library. *Blount.*

PAPER-*office* is alfo the name of an office belonging to the court of King's-bench. *Blount.*

PAPHIS, in zoology, a name by which fome have called the gar-fifh. *Willughby*'s Hift. Pifc. p. 231.

PAPIA, in botany, the name of a genus of plants, called by Linnæus *orvala*. It has a monopetalous flower, fucceeded by four feeds. *Micheli*, 17. See ORVALA.

PAPILIO, *butterfly*. For the feveral parts of the *butterfly*, fee the articles ANTENNÆ, WING, TRUNK, &c.

Their arrangement into genera and claffes are in a great meafure taken from thefe feveral parts, and from the great ufes which they make of them. The general diftinction is that which divides them into the day and night kinds; we have among the birds fome few that fly abroad only by night, but thefe bear only a fmall proportion in number to the day-fliers: on the contrary, the number of *butterflies* which we fee fluttering about the fields and gardens, are fcarce fo many as thofe which fly abroad only by night. We often meet with thefe even in our houfes, flying about the candles, and the hedges fwarm with them: in the day-time we find them hid under the leaves of plants, and often, as it were, in a torpid ftate. In this condition they remain till evening, but they are fo cunning in hiding themfelves at this time, that it is difficult to fee one even in places where there are a great number. The way to difcover them is to beat and difturb the bufhes, or fhake the branches of trees in places where they are fufpected to be, and they will often be driven out in fwarms. In this cafe, they never fly far, but fettle again upon the firft tree or bufh they come to; and in fummer, if any one goes out into the fields or gardens, with a candle, in a calm and ftill night, there will numbers of different kinds of them almoft immediately gather about it. Thefe are called by naturalifts *night-butterflies*, *phalenæ*, and *moths*. *Reaumur*'s Hift. Inf Vol. I. p. 1. 330.

The feveral kinds of *butterflies* that have thofe various inclinations, have alfo external characters by which they may be diftinguifhed; all thofe which have buttoned *antennæ*, or *club antennæ* are of the diurnal kind, and are never feen flying about candles in the night. There are other forms of the *antennæ* alfo, which are peculiar to the day *butterflies*; and the night ones are diftinguifhed by their having the plumofe, the prifmatic, or the conic ones. See ANTENNÆ.

Thofe which fly about our candles are always of one of thefe three kinds. It is not, indeed, to be wholly affirmed, that no one of thefe kinds is ever feen flying by daylight, fince in woods and thickets we often fee them fluttering about without having been difturbed; but all that are thus caught flying are males, and are that time feeking after the females to couple with them, thefe being all fixed immoveably under the leaves and on the branches of trees.

The common kinds that we fee fly about from flower to flower are all of the day kind: a few fpecies of the *phalenæ* fometimes flutter about the thiftle flowers, and feem to fuck them; but thefe are feldom feen; and among the moths, or night kinds, as we call them, there are a great many that never fly about by night any more than by day, and, indeed, make no ufe of their wings at all.

It is alfo a fingular obfervation, that the moths which fly about our candles, whether in the houfe or abroad in the gardens, are all males: the females never do it. The male of the glow-worm flies in the fame manner at a candle, thinking it the light of his female; and it is poffible, that the female moths may, in the night, yield a light that affects the eyes of the male of the fame fpecies, tho' it be infenfible to our view. See Tab. of Infects, Nº 10.

The great general diftinctions of the *butterflies* into day and night kinds being made, it is neceffary to have recourfe to numbers of other fub-diftinctions, in order to arrange them in any method; and thefe can by no means be taken from them in their prior ftate of caterpillars, many of them being in that ftate alike in all their general characters, tho' of different genera in their flying ftate.

As the *antennæ* ferve for diftinctions of the *butterflies* into claffes, fo do their trunks into genera; but thefe are only capable of diftinguifhing a few, the flat and the round being their principal diftinction. Mr. Reaumur has obferved, that the day *butterflies* all have thefe trunks, but that many of the night kinds want them. The wings, however, give the greateft variety of generical characters among thefe animals. The fhape of thefe, and the manner in which thefe creatures carry them, when walking and at reft, ferve as great and effential diftinctions. *Reaumur*'s Hift. Inf. Vol. I. P. 1. p. 334.

The inferior wings, in fome certain pofitions of the animal, hide the fuperior ones; but this is rare, and as the fuperior are moft in fight and obvious, the characters are moftly drawn from them. All the wings are of a triangular form, but they have their differences; fome being rectilinear, fome curvilinear, and fome mixtilinear: one of thefe angles is the place of joining of the wing to the body of the animal, and this is called by naturalifts the fummit of the wing; the angle is here broke off, to give more room to a firm joining on, otherwife this would be that part of the wing which would make the fummit of the triangle. The two fides are called interior and exterior; the firft, is that neareft the body of the creature; the other, the oppofite one. The bafe or end of the wing, is that part which is oppofite to the fummit, and forms the verge of the wing endways. The different proportions which thefe three parts of the wing bear to one another, are the origin of a great variety of figures in the whole. When the exterior and interior fide, or as they may be called in other words, the upper and under rib or verge of the wing, are nearly ftrait and equal, the whole wing then forms an ifofceles triangle, or a fection of a curve, according as the bafe is ftrait or convex; and the angle is larger or fmaller according as the bafe is more or lefs broad. The differences of the exterior and anterior edges from one another, give alfo a great number of varieties in the form. The inner edge is ufually the fhorteft, and this is the cafe in various different fpecies. The bafe alfo has its varieties in figure, as remarkable as the reft; it is fometimes ftrait or plane, fome-

times concave, and often convex: in some species the edge of it is perfectly smooth and even, and in others it is more or less deeply indented; and in some of the species it is jagged, and in some few instances one of the jaggs is so far extended from the rest of the wing, as to form a sort of tail. The wings are also in some very large, in others small, in proportion to the body. The two pairs have also great varieties in their proportion one to the other; in some species the inferior pair are nearly or wholly as large as the superior, and in others they are very small in comparison of them; and in some species the under wings are remarkably longer than the upper.

The differences in the manner of the *butterflies* carrying their wings has been more considered by Reaumur than by any author who went before him He observes, that some of the species carry their wings perpendicular to the thing they sit upon; others carry them plain or level with the horizon; and others let them fall below that level: these are called the drooping-wing kind. Some others form a sort of canopy with them, to cover their bodies; and others makes them as it were embrace their bodies. The colours of the wings make excellent distinctions for the several species; but they are not at all fit for generical distinctions.

It has been already observed, that there are three kinds of antennæ which are peculiar to the day *butterfly*, but the distribution under these alone would be too large; the species of the button-horned ones being alone greatly too numerous to be held altogether. It is necessary, therefore, to take in with these the positions of the wings, according to the preceding differences, and the day *butterflies*, or *papilios*, are thus distinguished into seven classes. *Reaumur*'s Hist. Inf. Vol. I. P. I. p. 344.

Class 1. Contains those *papilios* whose antennæ are terminated by buttons, and whose wings, when at rest, are placed in a perpendicular direction to the thing the creature sits upon, the under edges of which embrace the lower part of the body, and whose six legs are all employed in sustaining the body, and in walking. The black-spotted white *butterfly*, produced from the beautiful cabbage carterpillar, is one of the *papilios* of this class.

Class 2. Contains the *papilios* of the same characters with the former in all respects, except that they use only four of their legs in sustaining the body and in walking. The two anterior legs in the flies of this class are held in a bent posture, and are furnished with a downy part at their ends, and seem to serve as a sort of arms. These *papilios* in general are produced from the prickly caterpillars. The solitary nettle kind gives us an instance in its *papilio*.

Class 3. Contains those *papilios* which agree in all respects with the former, except that their two anterior legs, which they use as arms and never in walking, are not terminated by downy ends, but are fashioned like the other legs at the extremity, only so small, that it requires a microscope to distinguish them. There is an instance of this class in a common grey and yellow *papilio*, that is found in pastures among the grass in June, July, and August.

Class 4. Contains those *papilios* which have buttoned antennæ, as the others, and which carry their wings, when at rest, in a perpendicular direction to the thing they sit upon; but, as the former have the inferior edge of their wings bent round the under part of their body, so in these the inferior edge is bent upwards in both pair of wings, and embraces and covers the upper part of the body. However obvious this distinction may be, there is another yet more plain one in this, that all of this class have one of the jaggs of the wing so far extended beyond the rest of the verge, that it forms a kind of tail, and they are called the tailed *butterflies*. These use all their six legs in walking.

Class 5. Contains those *papilios* which have six real legs, which they use as such, and their horns terminated by buttons as the others; but whose wings, when they are in repose, are not elevated perpendicularly to the thing they sit on, as in the four preceding classes, but are held in an horizontal direction, or at the utmost never meet in an angle over the back. We have an instance of this class in a *butterfly* bred from a smooth caterpillar of the marsh mallow.

Class 6. Contains those *papilios* which have club antennæ, that is, such antennæ as gradually increase in thickness from their origin to their extremity. See Feelers. These are that class of *papilios* which are always upon the wing, and buzz about flowers without ever settling upon them. They dart their trunks into the flower while they sustain themselves in the air, and have a way of holding themselves in poize, like a kite or other bird of prey; but when they are busy about the flowers, they have their wings in continual motion, and make a humming noise, like the humble bees. Mad. Merian has called all these *phalenæ*, or night *butterflies*, but they are all truly of the day kind. The French, from their poizing themselves on the wing, and making that humming noise, call them *eperviers*, and *papilions-bourdons*. Of this class are those small species called the fly *butterflies*, whose wings are only covered in part with dust or scales, the remainder being transparent and glassy, as some express it. *Reaumur*'s Hist. Inf. Vol. I. p. 1, 356.

Class 7. In this last class are comprehended those *papilios* whose antennæ are large at their origin, smaller afterwards, and finally terminated by an oval head; and which differ from the club antennæ in having no pencils of hairs at the end. This class is not very numerous, and the most frequent instance we have of it is in a painted kind, which we frequently find on blades of grass, in meadows in July. This flies little in the day time, but is usually found fixed to a plant, as the moths are. Mad. Merian and others have thence called it a *phalena*, or *night-fly*; but the truth is, that it flies no more by night than by day light, but is a lazy creature which makes very little use of its wings. See Phalenæ.

There is some appearance from one of Mad. Merian's tables, *viz* the 20th, that an eighth class of these day *papilios* should be found, she having figured one with conic granulated antennæ, common to some of the moths. If this observation be just, or if any new ones of a like kind should demand it, the classes may be easily enlarged *Reaumur*'s Hist. Insect.

The world is well acquainted with the beauties of this part of the animal creation, but Mr. *Reaumur* has given accounts of some very singular species, which deserve a peculiar regard.

One species of these he has called the *bundle of dry leaves*. This, when it is in a state of rest, has wholly the appearance of a little cluster of the decayed leaves of some herb. The position and colour of its wings greatly favour this resemblance, and they have very large ribs, wholly like those of the leaves of plants, and are indented in the same manner at their edges as the leaves of many plants are. This seems to point out the care of nature for the animal, and frequently may preserve it from birds, &c.

The *skull butterfly* is another singular species, so called from its head resembling, in some degree, a death's head, or human skull. This very remarkable appearance is terrible to many people, but it has another yet greater singularity attending it; which is, that, when frighted, it has a mournful and harsh voice. This appeared the more surprizing to Mr. Reaumur, as no other known *butterfly* had any the least voice at all; and he was not ready of belief that it was a real voice, but suspected the noise, like that of the cicadæ, to be owing to the attrition of some part of the body; and, in fine, he, by great pains, discovered that this noise was not truly vocal, but was made by a hard and brisk rubbing of the trunk against two hard bodies between which it is placed.

Another *butterfly* there is, so small, that it might be mistaken for a very small fly. This is certainly the extreme in degree of size of all the known *butterflies*, and cannot but have been proportionably small in the state of a caterpillar and chrysalis: this creature spends its whole life in all the three stages of caterpillar, chrysalis, and *butterfly*, on the leaf of the celandine. It lives on the under side of the leaf, and tho' in the caterpillar state it feeds on it, yet it does no damage. It does not eat the substance of the leaf, but draws from it only a fine juice, which is soon repaired again, without occasioning any change in the appearance of the leaf. This species is very short lived, and passes through its three states in so short a time, that there are frequently ten generations of it in one year; whereas in all the other *butterflies*, two generations in the year are all that are to be had. These two generations are sufficient to make a prodigious increase: in a large garden, if there are twenty caterpillars in spring, these may be overlooked, and there may be easily concluded to be none there, even on a narrow search; but if these twenty caterpillars afterwards become twenty *butterflies*, ten of which are male and ten female, and each female lay the same number of eggs that the common silk-worm does, that is four hundred; if all the caterpillars hatched of these become *butterflies*, and these lay eggs in the same proportion, which remain the winter, and come to be hatched in the succeeding spring; then from these twenty, in only one year, you will have eight hundred thousand; and if we add to this the increase of these in a succeeding year, the account must appear terrible, and such as no art could guard against. The great ruler of the world has put so many hinderances in the way of this over-abundant production, that it is very rare such years of destruction happen. Some such have happened, however, and much mischief has been dreaded from them, not only from their eating all the herbage, but from themselves being eaten with herbs in sallads and otherwise; but experiments has proved this an erroneous opinion, and they are found to be innocent, and eatable as snails or oysters.

Caterpillars in general are by some supposed poisonous to the touch. Mr. Reaumur has proved by repeated experiments, that all the smooth ones are perfectly clear from this accusation, and may be handled with perfect safety; but the hairy ones are capable of producing great pain and itching after the touching them. These pains are not only felt in the hands, but also in the face, or any other part; and that even tho' the animal have not been touched, if it have only been brought near the part. The spolia, or cast skin of these animals, have also the same effect; but then it is absolutely necessary they should be touched. This unquestionably carries the appearance of the effect of a poison to vulgar eyes, but the case will appear otherwise to those who will examine into the whole more nearly. The mischief occasioned by these creatures

comes on very quick, and sometimes continues many hours, sometimes even three or four days.

The explication of this by Mr. Reaumur, is only this, that these caterpillars have, beside their coarse and large hairs which we see them covered with, a vast number of others, which are so extremely small and fine, as to be invisible to our eyes. These are sharp-pointed, very rigid, and are loosly fastened to the creature's body; so that they separate from it on the lightest touch: these make a sort of atmosphere of fine darts surrounding them every way; and many of the species of hairy caterpillars have evidently a method of darting these out in great numbers. When the hand of any one is put toward this creature, so as to come within the reach of these small darts, it immediately discharges a whole shower of them, and of these a great number enter the pores of the skin, and a great number more lie along upon it, ready to enter, as soon as any accident changes their posture. If while the hand be thus covered with these weapons, whose smallness, tho' it makes them invisible, yet does not incapacitate them from being very troublesome, be moved up to the face, or the cheeks, or eyes, rubbed with it, it is easy to conceive, that many of these little darts will be made to lodge in the skin on which the hand where they lie is rubbed; and the consequence must be a greater itching, pain, and swelling in these tender parts, than on the hand. And thus is produced by simple means, what is by many esteemed the effect of a piercing and penetrating poison. And thus are the strangest appearances often explained by the most simple means.

As it has been observed, that the abundance of caterpillars would be a terrible mischief to mankind if they were subject to no accidents in their increase, it may be proper to examine what are the means by which gracious providence has provided against an over supply of them. Many of the species are great devourers, and feed on one another; but they have all much more destructive enemies; these are reptiles like themselves, a sort of worms, in a state of passage, at the end of which they are to pass thro' the chrysalis state into that of flies or beetles. Even the small species of butterfly, which lives on the celandine, has its enemies proportioned to its own size; and the same leaf of the plant is usually covered at the same time with these butterflies, their chrysalises, and their caterpillars, and with these small beetles, their chrysalises and worms all confusedly together; and by their smallness they are not easily distinguished one from another. The caterpillars of this small species are very unhappily circumstanced; they have not only an open war to carry on with the worms of these beetles, which are continually attacking them, and piercing their bodies and sucking their juices; but they have much more terrible intestine enemies, a sort of small worms which they carry within their bodies, and which eat away their flesh within the skin.

The first people who observed these creatures, supposed them the young of the caterpillars; but this was not only wholly out of the course of nature, but the cruelty of the thing gave it no title to belief. The true history of these little worms bred within the body of the caterpillar, is, that they are not its children, but its most cruel enemies; they are deposited there by a species of fly, which at the time of laying her eggs pierces the skin of the caterpillar with an instrument she carries on the hinder part of her body for that purpose; in the same manner in which the fly which occasions the galls on oaks, pierces their wood. She deposits her eggs in the wound she has made, the skin of the caterpillar heals over the place, and the creature feels no inconvenience at first from the wound; but the heat of her body soon hatches these eggs, and they producing maggots, which are naturally flesh-eaters, they feed on the flesh among which they are produced, and eat the miserable creature up alive, without breaking its skin; and they are often so numerous, that when they are increased to their destined size, they fill up the whole body of the caterpillar, scarce leaving a sufficient space for the entrails. What might appear very singular, is, that during all this time the animal which carries these intestine enemies, seems well and at ease; it eats and grows larger, as it would do without them. Mr. Reaumur inquiring into the reason of this, found that caterpillars have a long canal reaching from the mouth to the anus, and serving for stomach, oesophagus and intestines; and besides this, there is throughout its whole body, a cellular and fatty substance. It is on this that these devourers feed, without touching the intestine, or breaking its communication, which would kill the animal, and deprive them of a supply of food. Thus they are supplied from the great quantity of food the caterpillar takes, with a renewed flesh; and when the caterpillars which are infested with them are opened, this always is found to be the case; they being lodged in, and feeding intirely on this cellular substance, or the fat contained in it.

When these worms have arrived at their full growth, they come out of the body of the caterpillar, but this not all the same way, or by any natural passage, but each eats its way thro' the skin. As soon as they are got out they go to work, to spin themselves shells, or cases for their transformation: these they make upon the spot, and place them side by side, either upon the body of the caterpillar, or close by it; and stick so close to one another, that they appear one case or shell. This is a circumstance which has contributed not a little to the belief of their being the natural produce of the caterpillar, as people have thought they were all inclosed in one case of that creature's spining for them. The caterpillar dies of the wounds it has received by their eating their way out, added to the loss of what they had eat from it; and after a few days, the worms hatch out of this their chrysalis state into that of the fly, like the parent that lodged the eggs, from whence they arose in the body of their supposed parent.

Sometimes the caterpillar enters into its chrysalis state before these worms arrive at the time of their going out of its body; and in this state sometimes they eat thro' the sides of the case, but more frequently they remain in it, and become flies there, saving themselves, by this means, the trouble of spining. Some species of caterpillars are so greatly infested with these worms, that they are very seldom found free from them; and it is not more than one in twenty that by this means comes to the butterfly-state. Here then is one great stop to the increase of these destructive animals. Another cause of their destruction is also very common, and not less singular: a sort of flies lay their eggs in the eggs of the butterflies; and the maggots produced from these eat up the embryo caterpillars.

These worms are very terrible to the caterpillars by their number, but the small birds are much more so by their strength; multitudes of caterpillars are annually destroyed by these creatures, either for their own food, or for that of their young. In this also there seems a sort of regularity; for as the caterpillars have their taste for peculiar species of plants, so the birds have theirs for peculiar species of caterpillars. In general, they do not love the hairy kinds; but tho' this accident is a defence to them in that state, it is but a temporary one; for they are as subject to be devoured when butterflies, as those of the smooth sorts; and those which have escaped danger in their two first states of life, are by their size and conspicuous colours, very much exposed to these devourers in this their last stage. Each of their states has its appropriated enemies; and it is the same with respect to us, whether it is in the caterpillar, the chrysalis, or the fly-state, that the creature is destroyed; since the propagation is equally stopped in which ever it happens, provided only that it be before the laying of the eggs; all the difference, at the utmost, however, is, that if they are destroyed in the beginning of the caterpillar-state, a few leaves or herbs are saved that would have been eaten by them. Memoirs Acad. Science, Ann. 1736. See Tab. of Insects.

PAPILIO-*musca*, in natural history, a name given by some authors to a series of small insects, which seem to be of a middle nature, between the fly and the butterfly classes. Its wings are in part covered with those scales in form of dust, which render the wings of the butterfly kinds opake, and in part are transparent and glassy. Reaumur has called the wings *ailes vitrees*, glassy wings. *Reaumur's* Hist. of Inf.

PAPILION-*bourdon*, in natural history, a name given by the French authors to a sort of butterflies, which while they feed keep upon the wing with a humming noise like that of the humble-bee. *Reaumur's* Hist. of Insects. See the articles EPERVIERS and PAPILIO.

PAPILION-*a-queue*, *tailed butterflies*, a name given by the French naturalists to a sort of butterfly, of which there are several species. The feeds of the wings of these butterflies are jagged, and one of the jaggs runs out so far beyond the rest as to represent a sort of tail issuing from the creature. *Reaumur's* Hist. of Insects.

PAPILLARIS, in botany, a name used by some authors for the common *lampsana*, or *nipple-wort*. *Chabræus*, p. 318. See the article LAMPSANA.

PAPILLOSE, among botanists. See LEAF.

PAPIO, in zoology, the name of those species of monkeys which we call *baboons*. The word seems not yet properly determined as to the species which are to be comprehended under it; but what we usually acknowledge for *papiones* or *baboons*, are such as have long heads like a dog, and very long tails, and are of the number of those called by authors *cynocephali*.

PAPULÆ, a name used by many authors for eruptions of various kinds upon the skin, but appropriated by Bontius to those reddish and rough eruptions thrown out upon the body by sweat in the East Indies. These are thrown out all over the surface of the body, and at their first appearance are accompanied with an intolerable itching and desire of scratching.

Strangers are more exposed to these eruptions at their first arrival in these countries, than the natives, or those who have long resided there; as they are also to the bitings of the musquitos, than which they are not less frequent: hence a new comer into the country is distinguished by these troublesome maladies. The natives call him *organ bearon*, that is, a new arrived man; and tell him these complaints are a tax upon him for consuming the provisions. They call themselves *organ lamme*, or *veterans*, and honour with the same name such strangers as have lived long in the country.

The *papulæ* are in themselves no way dangerous; but when they are rashly and ignorantly treated, or when the skin is torn off

off from them by the nails, they often are the occaſion of malignant and very troubleſome ulcers, that are not eaſily cured.

Bontius, whoſe long reſidence in this part of the world gave him many opportunities of obſerving theſe *papulæ* in all their ſtages, adviſes people, to prevent danger and remove their troubleſome itching, to foment all the parts where they appear with a mixture of vinegar, water, and ſaltpetre; or if this be required yet more acrid, to add to it juice of lemons, and uſe it as before. The effect of this application is at firſt an intenſe pain, but this ſoon decreaſes ſo far, as to become leſs troubleſome than the intolerable itching of the parts. He gives great caution alſo againſt purging medicines, however mild; for by theſe the matter which cauſes the *papulæ* is often carried to the bowels, and produces dyſenteries. The cure is either to be wholly left to nature, or aſſiſted by ſudorifics. *Bontius* de Med. Ind.

PAR (*Cycl.*)—PAR *acceſſorium*, in anatomy, See the article ACCESSORY, *Cycl.*

PARABELE, in ichthyology, a name given by Marggrave to the flying fiſh, the *milvus hirundo* and *cuculus* of ſeveral authors. Theſe are names, however, ſo little expreſſive of the characters of fiſh, that they are applied by different authors to the different ſpecies. Artedi is the only author who has reduced this part of natural hiſtory to a regular ſyſtem; he makes this fiſh a ſpecies of the *triglia*, and diſtinguiſhes it by the name of the *triglia* with the head a little aculeated, and with a ſingular fin placed near the pectoral fins. See the articles MILVUS and TRIGLIA.

PARABOLIC (*Cycl.*)—PARABOLIC *aſymptote*, in geometry, is uſed for a *parabolic* line approaching to a curve, ſo that they never meet; yet by producing both indefinitely, their diſtance from each other becomes leſs than any given line.

There may be as many different kinds of theſe *aſymptotes* as there are parabolas of different orders. See *Mac Laurin's* Flux. B. 1. ch. 10.

When a curve has a common parabola for its *aſymptote*, the ratio of the ſubtangent to the abſciſs approaches continually to the ratio of two to one, when the axis of the parabola coincides with the baſe; but this ratio of the ſubtangent to the abſciſs approaches to that of one to two, when the axis is perpendicular to the baſe. And by obſerving the limit to which the ratio of the ſubtangent and abſciſs approaches, *parabolic aſymptotes* of various kinds may be diſcovered. See *Mac Laur.* Flux. Art. 337.

PARABOLIC *ſpiral*, in conics. See HELICOID *parabola*, *Cycl.*

PARACENTESIS (*Cycl.*)—See TAPPING.

PARACOPE, a word uſed by Hippocrates to expreſs a ſlight delirium in fevers.

PARACRUSIS, a word uſed by Hippocrates, and by many other writers, and expreſſing the ſame as *paracope*, a ſlight delirium in a fever.

PARADIGRAMMATICE, is uſed by ſome for the art of making all ſorts of figures in plaiſter. The artiſts in this are called *gypſochi*.

PARADISÆA, in zoology, a name uſed by ſome authors for the bird *manucodiata*, or *avis paradiſæa*, the bird of paradiſe, by others. In the Linnæan ſyſtem this makes a diſtinct genus of birds of the order of the *picæ*, the diſtinguiſhing characters of which are, that they have two ſingular and extremely long feathers, which are neither inſerted in the wings nor rump. See Tab of Birds, N°. 6 and *Linnæi* Syſtem. Nat. p. 44.

PARADISIACA, in botany, a name given by ſome authors to the *arbor* vitæ, or *thuya*. *Chabræus*, p. 73.

PARADOX (*Cycl.*)—Geometricians have of late been accuſed of maintaining *paradoxes*; and it muſt be owned, that ſome uſe very myſterious terms in expreſſing themſelves about aſymptotes, the ſums of infinite progreſſions, the areas comprehended between curves and their aſymptotes, and the ſolids generated from theſe areas, the length of ſome ſpirals, &c. But all theſe *paradoxes* and myſteries amount to no more than this: that a line or number may be continually acquiring increments, and thoſe increments may decreaſe in ſuch a manner, that the whole line or number ſhall never amount to a given line or number.

The neceſſity of admitting this is obvious from the nature of the moſt common geometrical figures: thus, while the tangent of a circle increaſes, the area of the correſponding ſector increaſes, but never amounts to a quadrant. Neither is it difficult to conceive, that if a figure be concave towards a baſe, and have an aſymptote parallel to the baſe, as it happens when we take a parallel to the aſymptote of the logarithmic curve, or of the hyperbola, for a baſe; it is not difficult to conceive, I ſay, that the ordinate in this caſe always increaſes while the baſe is produced, but never amounts to the diſtance between the aſymptote and the baſe. In like manner, a curvilinear area may increaſe while the baſe is produced, and approach continually to a certain finite ſpace, but never amount to it; and a ſolid may increaſe in the ſame manner, and yet never amount to a given ſolid. See LOGARITHMIC *curve*

A ſpiral may in like manner approach to a point continually, and yet in any number of revolutions never arrive at it; and there are progreſſions of fractions which may be continued at pleaſure, and yet the ſum of the terms ſhall be always leſs than a given number. See *Mac Laurin's* Fluxions, B 1. ch. 10. ſeq. where various rules are demonſtrated, and illuſtrated by examples, for determining the aſymptotes and limits of figures and progreſſions, without having recourſe to thoſe myſterious expreſſions which have of late years crept into the writings of mathematicians. For, as that excellent author obſerves elſewhere, tho' philoſophy has, and probably always will have myſteries to us, geometry ought to have none.

PARÆA, in zoology, the name of a ſpecies of ſerpent, called alſo *anguis æſculapii*. It is a perfectly innocent and harmleſs creature, and is ſo little dreaded by the inhabitants, that it is common about their houſes, and even ſometimes gets into their beds. Its mouth is full of very ſmall teeth, and when much provoked, it is ſometimes known to bite, tho' without any bad ſymptoms attending the wound. It is a very long kind, and is of a yellowiſh green colour on the ſides and blackiſh on the back: it has two ſmall eminences on the neck, and between them two ſmall ſinews. It is very common in Spain, Italy, and moſt other of the warm countries. *Ray's* Syn. Anim. p. 291.

PARAGAUDÆ, among the Romans, a ſort of wreaths, either wholly of gold, or of ſilk adorned with gold, which were interwoven in garments, and not ſowed to them. The garment was ſometimes of one colour, in which was woven one *paragauda*; others were of two colours, and had two *paragaudæ*; and ſome had three colours, and three *paragaudæ*. They were worn both by men and women.

PARAGOGE (*Cycl.*) a word uſed by medical writers to expreſs a reduction of luxated bones.

PARAGONE, in natural hiſtory, the name given by many to the baſaltes, a black marble, uſed as a touchſtone. See the article BASALTES.

PARAGUA, in zoology, the name of a Braſilian parrot, of the ſize of our common green parrot; but its back is all black, and its breaſt and the forepart of its belly are of a beautiful red. Its eyes are black, with a red circle round them; its beak brown, or a very duſky grey, and legs and feet grey. *Marggrave*, Hiſt. of Braſil.

PARALAMPSIS, a word uſed by medical writers to expreſs a cicatrix in the tranſparent part of the cornea of the eye.

PARALIA, Παραλια, in antiquity, a day kept in memory of an antient hero, called Paralus. *Potter*, Archæol. Græc. l. 2. c. 20. T. 1. p. 424.

PARALIA was alſo the name of one of the Athenian tribes. *Potter*, ibid. T. 1. p. 49.

PARALLAXIS, in the medical writers, expreſſes a mutual change in the ſituation of the parts of a broken bone, as when the two fragments ſlip to the ſides of one another.

PARALLEL (*Cycl.*)—PARALLELS *of declination*, in aſtronomy, are circles parallel to the equinoctial, imagined to paſs through every degree and minute of the meridians, between the equinoctial and each pole of the world.

PARALLELA, a word uſed by medical writers to expreſs a ſort of ſcurf or leprous appearance, affecting only the palms of the hands. It is a ſymptom of the pox.

PARALLELOGRAM (*Cycl.*)—PARALLELOGRAM *of the hyperbola*, in geometry, is uſed for the *parallelogram* formed by the two aſymptotes of an hyperbola, and the parallels to them, drawn from any point of the curve. A *parallelogram* thus formed, is of an invariable magnitude in the ſame hyperpola; and the rectangle of its ſides is equal to the power of the hyperbola. L' Hopital, Sect. Coniq. Art. 99—101. See the article POWER, *Cycl.*

This *parallelogram* is the modulus of the logarithmic ſyſtem; and if we take it as unity, the hyperbolic ſectors and ſegments will correſpond to Napier's or the natural logarithms. If the *parallelogram* be taken $= 0.43429$, &c. theſe ſectors and ſegments will repreſent Briggs's logarithms. See the article LOGARITHM.

Huygens has made uſe of this term, De cauſ. gravitat. in fin. See LOGARITHMIC-*curve*.

PARALLELOGRAM-*protractor*, a mathematical inſtrument, conſiſting of a ſemicircle of braſs, with four rulers in form of a *parallelogram*, made to move to any angle: one of theſe rulers is an index, which ſhews on the ſemicircle the quantity of any inward or outward angle.

PARALLELLOPIPED (*Cycl.*)—The *parallellopiped* with oblique angles, is a figure very common to many kinds of ſtones, eſpecially of the ſofter ſort. The common cryſtallizations of grottos break naturally into fragments of this ſhape; and the ſtalactitæ which hang down from their roofs in form of icicles, are originally ſmall hollow pipes formed by the water which continually trickles down drop by drop; and whoſe outer ſurfaces, fixing themſelves by their ſmall baſes, form by degrees a ſort of blunted pyramids, which, like ſo many rays from the axis, which is the hollow pipe, grow hollow at laſt. This axis ſeems to be compoſed of plates, almoſt cylindrical, laid one over another; but if broken, the whole divides into fragments of a *parallellopiped* figure: the blunted pyramids that are about the axis divide themſelves at firſt into other blunted pyramids; but afterwards almoſt all theſe fragments divide of themſelves into other fragments of a *parallellopiped* figure, this ſeeming every where the ultimate ſhape of the particles.

In the mountain of Barege there is found a vaſt quantity of aſbeſtus; the ſtone upon which this grows, tho' in itſelf of

no determinate figure externally, yet always breaks into regular *parallellopipeds*: nor is this peculiar to theſe ſtones found naturally concreted on the ſurface or within the bowels of the earth, but it is alſo found in ſuch as are concreted by means of art out of the water in which they are originally ſuſpended. The water of the fountain de Salut, near Bagneres in Gaſcony, when evaporated to a certain degree, yields a ſcum on the ſurface, which alſo adheres to the ſides of the veſſel; and this ſcum, examined by the microſcope, is found to be compoſed of many regular *parallellopipeds*. If the ſame waters, and thoſe of ſeveral other ſprings, be evaporated to a drineſs, there remains a white ſhining powder, out of which the microſcope can direct us to ſeveral the like regular figures. Phil. Tranſ. N. 472, p. 32.

PARALLELLOPIPEDIA, in natural hiſtory, the name of a genus of ſpars, thus called, becauſe regularly of a *parallellopiped* form.

They are pellucid cryſtaline ſpars, externally of a determinate and regular figure, always found looſe, detached, and ſeparate from all other bodies, and in form an oblique *parallellopiped*, with ſix parallelogram ſides and eight ſolid angles, eaſily fiſſile, either in an horizontal or perpendicular direction, being compoſed of numbers of thin plates, and thoſe of very elegantly and regularly arranged bodies, each of the ſame form with the whole maſs, except that they are thinner in proportion to their horizontal planes; and naturally fall into theſe and no other figures, on being broken with a ſlight blow.

Of this genus there are four known ſpecies. 1. The hard pellucid and colourleſs one, called the iſland cryſtal of authors. See ISLAND *cryſtal*. 2. A dull and whitiſh kind, found in France, Germany, and England, particularly in the Derbyſhire and Yorſhire lead-mines, and about Scarborough. This has the ſame property with the former, of giving a double refraction; but it is ſo dull and opake, that it does not ſhew it ſo elegantly. 3. A ſoft, whitiſh, and very bright one, found principally in the lead-mines of Yorkſhire and about the ſeaſhores of that county. And, 4. a dull, hard, and pale brown one: this is found in the lead-mines of the ſame county, and in ſome parts of Ireland. All theſe ſpecies have the ſame power of double refraction with the firſt, but are too opake to ſhew it ſo beautifully, and often have not tranſparence enough to make it at all diſtinguiſhable. *Hill*'s Hiſt. Foſſ. p. 333.

PARALOPHIA, a word uſed by Keil and ſome other anatomical writers, to expreſs the lower and lateral part of the neck.

PARALOURGES, Παραλουργες, among the antients, a kind of garment, with a purple clavus on each ſide. *Pitiſc.* Lex. Ant. in voc. See CLAVUS.

PARALYSIS, in botany, *&c.* the ſame with *primula veris.* See PRIMULA *veris.*

PARAMERIA, a word uſed by the antients to expreſs the internal part of the thighs.

PARAMESE, in the Greek diagram, or ſcale, was the note above the meſe, which anſwers to a-la-mi-re of Guido's ſcale. V. *Wallis*'s Append. Ptolem. Harm. p. 157. Hence, as the *parameſe* was the firſt of the diazeugmenon tetrachord, it will be equivalent to Guido's higheſt ♮ mi. See DIAGRAM.

PARAMESOS, a word uſed by ſome to expreſs the ring-finger, that next the little one.

PARANETE, in the antient muſic, was a name ſometimes uſed to ſignify the next note, or chord to the nete, or laſt note of a tetrachord. See TETRACHORD.

Hence it might be called the penultimate chord. It was otherwiſe, and more properly called, *lichanos*, or index: the reaſon of which ſee under LICHANOS.

PARANETE *diezeugmenon*, in the Greek muſic, was the penultimate note of the *diezeugmenon* tetrachord, and anſwers to Guido's de-la-ſol-re. *Wallis*'s Append. Ptolem Harm. p. 157. See DIAGRAM.

PARANETE *hyperbolæon*, in the Greek muſic, was the penultimate note of the *hyperbolæon* tetrachord, and anſwers to Guido's g-ſol-re-ut. *Wallis*'s Appen. Ptolem. Harm. p. 157. See DIAGRAM.

PARAPHORA, a word uſed by the antients to expreſs a ſlight kind of delirium, or light-headedneſs in a fever: ſome have made it ſignify a delirium in general.

PARAPHRENITIS, in medicine, the name of a diſtemper which conſiſts in an acute ſymptomatic fever; which is the means uſed by nature to break through inflammatory ſtates in the diaphragm. The alienation of the mind in this diſeaſe is owing to the conſent of the nerves.

Signs of it. This is always attended with a moſt violent and painful cardialgia, or heart-burn; inſomuch, that the perſon cannot bear the leaſt touch of a finger on the region of the breaſt or ſtomach. It always brings on alſo a tumor of the præcordia, and an alienation or roving of the mind, which is always ſenſible in the words and actions of the perſon, but is not ſo great as in the true *phrenitis*. The reſpiration is interrupted by frequent ſighings; belchings are very frequent; as alſo the diſcharge of a black matter by vomit. The mouth is dry and parched, and the tongue very white and furred; and there is great thirſt.

Cauſes of it. The moſt frequent cauſe of this is a ſudden tranſlation of the morbific matter in fevers to the diaphragm; a ſuppreſſion of natural hæmorrhages by the noſe, the hæmorthoidal veſſels, or by the menſes; an omiſſion of habitual bleedings, and the drinking cold liquors when the blood is heated by exerciſe; and finally, a tranſlation of the matter of a quinſey to this part.

Prognoſtics in it. This is a dangerous diſeaſe, but it has three ways of terminating, according to the diſpoſition of the patient's blood and humours: 1. Sometimes the matter which cauſed the obſtruction is eaſily diſcuſſed, and ſweats happening on the critical days, carry off the diſtemper. 2. Sometimes the matter is reſolved, indeed, but not ſo happily; the reſolution takes longer time, and the matter finally does not evacuate itſelf by ſweat, but is tranſlated to the ears, where it occaſions deafneſs, tumors, and other accidents; or to the joints, where it brings on either the gout or eryſipelatoſe diſorders: or, 3. The matter comes to ſuppuration; in which caſe, the perſon dies either within ſeven days, or, at the utmoſt within fourteen. The ſigns which preſage a gangrene in this diſeaſe, are violent hiccoughs, coldneſs of the extremities, violent internal heat, and clammy ſweats.

Method of cure. When, by a preceding error in the perſon's diet, the peccant matter remains in the primæ viæ, a gentle emetic is to be given, with the digeſtive medicines before it; and if the vomit does not operate, a few grains of emetic tartar are to be given afterwards. When the patient is of a plethoric habit, bleeding is extremely neceſſary; and ſometimes, where the ſymptoms require it, may be repeated to a third time. Twenty drops of the mixtura ſimplex may afterwards be given at a doſe, every four hours, in the morning; and in the afternoon, powders of purified nitre, with vitriolated tartar and crabs eyes ſated with juice of lemons: beſides theſe, there may be externally applied, plaiſters, with a large portion of camphor, to the breaſt and back; ſinapiſms, and other hot cataplaſms, to the ſoals of the feet; ſtimulating clyſters, and acrid ſuppoſitories have alſo their uſe in this caſe; and the application of leeches to the hæmorrhoidal veins, in people who have been ſubject to diſcharges from thence, are very often of ſingular ſervice. All the while there muſt be kept up a gentle tranſpiration, either by copious draughts of warm and weak liquors, or by lightly accidulating medicines. *Junker*'s Conſp. Med. p. 307, ſeq.

PARAPHROSYNE, a word uſed by ſome medical writers to expreſs a delirium, or an alienation of mind in fevers, or from whatever cauſe.

PARAPOTAMIA, in the materia medica of the antients, a word uſed at firſt as an epithet of diſtinction for a kind of Œnanthe, from which the œnanthine ointment of the Greeks was made; but afterwards uſed ſimply as the name of that plant. This kind of œnanthe was the moſt fragrant of all the kinds, and was therefore uſed for the making the ointment preferably to the reſt.

Theophraſtus makes a very great difference in the œnanthe of different places, obſerving, that the Cyprian kind was fragrant, and fit for making this ſweet ointment; but that the Grecian had no ſmell at all: and thence it probably aroſe, that the Greeks uſed afterwards the flowers of the wild vine for this purpoſe, and called them by the ſame name.

Pliny's account of this ointment is by no means to be depended upon. The whole paſſage where he names it, and the others of the like kind, is taken from the account of Apollodorus, in Athenæus; but it is ſo careleſly tranſlated by Pliny, that the author's ſenſe can ſcarce any where be made out. *Athenæus*, l. 15.

PARAPROSDOCIA, Παραπροσδοκια, in rhetoric, the ſame with *paradox*. See PARADOX, *Cycl.* and *Suppl.*

PARARTHREMA, a word uſed by medical writers to expreſs a ſlight luxation.

PARARYTHMOS, an epithet uſed by the antients to expreſs any kind of pulſe which did not ſeem ſuitable to the age and ſtate of the perſon.

PARASCEUE, (*Cycl*) in antiquity, a Greek word which ſignifies *preparation*. The Jews gave the name of *paraſceue* to Friday, becauſe being not allowed on the Sabbath to prepare their food, they provided the day before. Exod. xvi. 23. xxxv. 2. 3. *Calmet*. Dict. Bibl.

PARASCHIDES, a word uſed by chirurgical writers to expreſs the ſplinters of fractured bones, or the fragments of bones corroded by ſharp humours.

PARASEISMA, a ſort of exerciſe preſcribed by the Greek phyſicians in many caſes. It was a general concuſſion of the body.

PARASEMUM, Παρασημον, among the antients, a ſign painted or carved on the prow of ſhips, by which they were diſtinguiſhed from one another. This ſign was commonly the figure or picture of ſome animal, as the bull, lion, *&c.* or of any other thing, as a mountain, tree, flower, *&c.* *Pitiſc.* in voc. and *Potter* Archæol. Græc. T. 2. p. 128.

PARASIOPESIS, Παρασιώπησις, in rhetoric. See the article PARALEPSIS, *Cycl.*

PARASITIUM, among the antients, a granary or place where the ſacred corn, deſigned for religious purpoſes, was preſerved. *Pitiſc*. Lex. Ant. in voc. See PARASITE, *Cycl.*

PARASPHAGIS, a word used by some anatomical writers to express that part of the neck which is contiguous to the clavicles.

PARASTREMMA, a name given by medical writers to a convulsive distortion of the mouth, or of any part of the face.

PARATHENAR-*major*, a pretty long muscle forming part of the outer edge of the sole of the foot. It is commonly called *hypothenar*, but very improperly, according to the proper signification of that word It is fixed backward by a fleshy body to the outer part of the lower side of the os calcis, from the small posterior external tuberosity all the way to the anterior tuberosity, there it joins the metatarsus; and at the basis of the fifth metatarsal bone, separates from it again, and forms a tendon which is inserted in the outside of the first phalanx of the little toe near its basis, and near the insertion of the *parathenar*-minor. *Winslow*'s Anatomy, p. 226.

PARATHENAR-*minor*, a fleshy muscle fixed along the posterior half of the outer and lower side of the fifth bone of the metatarsus; it terminates under the head of that hone in a tendon which is inserted in the lower part of the basis of the first phalanx of the little toe.

The tendinous insertion of this muscle is very closely united to the cartilaginous ligament; and the same thing is to be observed of the other muscles, which go to the basis of the first and second phalanges of the toes. In aged persons, some part of these ligaments are often turned to bone, and thereby form those hony portions which many have taken for distinct sesamoide bones. *Winslow*'s Anatomy, p. 226.

This muscle is more expressively named by Albinus, the *flexor brevis digiti minimi pedis*.

PARATI, in zoology, the name of a Brasilian fish of the mullet kind, much resembling that species called *curema*, or *taintra*, in all respects but size; and in the colour of its eyes, the iris of which, instead of the silvery colour it has in the *curema*, is of a fine yellow. Its flesh also when dressed, is drier than that of the *curema*. *Piso*'s Hist. of Bras. See the article CUREMA.

PARBUNCLE, in a ship, the name of a rope almost like a pair of slings; it is seized both ends together, and then put double about any heavy thing that is to be hoised in or out of the ship; having the hook of the runner hitched into it to hoise it up by.

PARCELLING, in ship-building, is caulking the seam of a ship, then laying over it a narrow piece of canvas, and then pouring on it hot pitch and tar. See PAYING.

PARDALIS, in zoology, a name by which many authors call the bird more commonly known by the name of *pluvialis*, and called in English the *grey* and *green plover*; birds of the size of the lapwing, and much esteemed at table. *Ray*'s Ornithology, p. 229.

PARDALIS is also used as the name for the leopard, called also *pardus*, *panthera*, and *varia*, by some. It is distinguished from the lion by its variegation of colour, and from the tyger by the disposition of those colours; which are in this creature always in round spots like eyes, as in the tyger they are in long streaks. The leopard is also less than the tyger.

PARDUS, in zoology, a name used by many for the *leopard*; the more accurate authors, however, use the word *pardalis*. See PARDALIS and LEOPARD.

PARDUS, in conchyliology, a name given by authors to a kind of shells, of the genus of the volutæ. We have three kinds of this shell: 1. A voluta spotted with black. 2. Another spotted with yellow. And 3. A very elegant one spotted with a redish colour. They are called *pardi*, or *leopard-shells*, from their distinct spots resembling those on the skin of a leopard.

PARE, in the manege. To *pare* a horse's foot is to cut his nails; *i. e.* the horn and sole of his foot; which is done with a butteris, in order to shoe him. See BUTTRESS, *Cycl.*

In England, the smith or farrier holds the horse's foot between his knees; in which posture he *pares* the foot, sets on the shoe, drives the nails, and rivets them, and this all alone without any assistance from the groom.

PARECBASIS, Παρέκβασις, in rhetoric, is used to signify the exaggeration of a crime, and not a digression from the question in hand, as some have thought. *Voss.* Rhet. l. 3. p. 364.

PARECHESIS, Παρήχησις, in rhetoric, the too frequent repetition of the same syllable, thus, *perire me malis malim modis*. *Voss.* Rhet. l. 5. p. 331.

PAREDRIA, a term used by Hippocrates to express an association of two or more diseases in the same patient, making what we call a complicated illness.

PAREDRI, Πάρεδροι, among the Athenians. When the Archon, Basileus, or Polemarchus, by reason of their youth happened not to be so well skilled in the laws and customs of their country, as might have been wished, it was customary for each of them to make choice of two persons of age, gravity, and reputation, to sit with them upon the bench, and direct them as there was occasion. And these assessors, or *paredri*, were obliged to undergo the same probation in the senate-house and public forum, with the other magistrates; and like them too, to give an account how they had behaved themselves in their respective trusts, when their office was expired. *Potter*, Archæol. T. 1. p. 77.

PAREIRA-*brava* (*Cycl.*)—The Portuguese name signifies the wild vine, and is given to a root first brought into Europe by Mr. Amelot, and celebrated by many at that time for its extraordinary virtues. The plant which produces it is not known, but is generally supposed to be of the vine kind. Mr. Geoffroy examined into its virtues carefully, and also its characters and distinctions; he found that there were properly two kinds of it: The one brown on the outside, and yellowish within. This is what was then most frequent in use; and the other white on the outside, and of a paler yellow or lemon colour within. This is said to be of a flesh colour on the outside where recent, and to turn white in drying; both are of a spungy or porous texture, yet considerably hard and woody; of a bitter taste, but with an admixture of a sweetish flavour like that of liquorice; and their usual size is from that of one's middle finger, to that of one's thumb.

The Portuguese were informed of the virtues of this root by the natives of the Brasils; and on trial extolled it above all the medicines in use. Their accounts of its efficacy were too exaggerated to gain credit with the judicious part of the world; but Mr. Geoffroy's experiments, which set its virtues in a much modester light, yet shew them to be very great; and that the root deserves to be for ever continued in use in medicine, and rekoned among the most valuable simples. The Portuguese pretend, that it dissolves the stone in the bladder; but tho' this is not true, Mr. Geoffroy found that it was admirable for breaking the common weaker fabulous concretions in the kidneys and ureters; and that the taking it was always attended with the voiding of large quantities of gravel He gave it also with great success, to persons afflicted with ulcers in the kidneys and bladder, and whose urine was purulent, and at many times totally suppressed: these suppressions of urine were always cured by it, and their urine became less thick and purulent; many also were perfectly cured of these complaints by a course of it, with the addition of balsam of capivi toward the end of the course.

This property of the *pareira-brava*, of dissolving thick humors, gave Mr. Geoffroy an opinion of trying it in humorous asthmas; and these obstinate cases often were greatly abated, and sometimes perfectly cured by it. The usual way of taking it, is in decoction, sweetening it in the manner of tea. Mem. Acad. Par. 1710.

PAREMBOLE, Παρεμβολή, in rhetoric, a figure wherein something relating to the subject is inserted in the middle of a period. All the difference between the *parembole* and *parenthesis*, according to Vossius, is, that the former relates to the subject in hand, whereas the latter is foreign to it. An example of each we have in Virgil, and first of the *parembole*.

Æneas (neque enim patrius consistere mentem
Passus amor) rapidum ad naves præmittit Achatem.

The following is an instance of the *parenthesis*:

——— *ipsique suos jam morte sub ægrâ*
(*Di melior a piis, errorem que hostibus illum*)
Discissos nudis laniabant dentibus artus.

Voss Rhet. l. 5. p. 334. See PARENTHESIS, *Cycl.*

PARENCEPHALIS, a name given by some authors to the *cerebellum*.

PARENTHESIS, Παρένθεσις, in rhetoric, is frequently confounded with *parembole*. See the articles PAREMBOLE, *Suppl.* and PARENTHESIS, *Cycl.*

PARERGON, in painting, an appendix, or piece added to the main design by way of ornament. *Hofm.* Lex. in voc.

PARER, in the manege, a term formerly used as a command to stop, but now exploded; all the riding-masters, when they have a mind the scholar should stop the horse, calling out *hola*. *Guillet*, in voc. See STOP.

PARETONIUM, in natural history, the name of an earth antiently found on the shores of Egypt, Cyrene, and the island of Crete; and used by the antients in painting

It had its name either from a part of Egypt near which it was gathered, or from the name of a town in that kingdom where it was usually sold. Vitruvius is of the first opinion, and Volaternus of the other.

There have been some differences among the earlier writers about the nature and origin of this substance; and much confusion and mistake among the moderns. Pliny imagined it formed of the froth of the sea coalesced into a solid mass, with the addition of some mud: Aldrovand thought it formed of the disunited particles of what he calls the fatter stones, such as lime-stones, and the like, washed from them by the motion of the water, and afterwards got together in that form. And Dalecshamp esteemed it a chalk, produced about the shores, which he adds was very white, fat, and glutinous, and could not be taken up without a mixture of some of the mud along with it. It is very clear, however, according to this very account, that the substance could be no chalk: viscidity and fatness, are qualities that cannot belong to an earth of that class; neither are we to imagine, that it was ever dug up from the flat parts of the shores; since if there was a stratum of it there, tho' ever so thin, it might certainly have been taken up pure.

Such were, however, the opinions of authors about this substance. Of late we have been taught to think it lost; but it is still common on the shores of most of the islands of the Archipelago, tho' not observed or regarded; and is truly a very heavy and tough clay of a fine white colour, found in masses of different sizes, generally as soft as the softer clays within the strata; and by rolling about on the beech in this state, it gathers up the sand, small shells, and other foulnesses we always find about it. It is most probable, that there are strata of it fine and pure in the cliffs there, and that the sea washes off masses of them in storms and high tides, which are what we find. *Hill's* Hist. of Foss. p. 17.

PARGET, in natural history, a name given to the several kinds of gypsum or plaister-stone, which when slightly calcined, make what is called *plaister of Paris*, used in casting statues, in stuccoing floors and cielings, and many other like occasions.

The word *parget*, tho' generally understood of all the gypsums, is, however, by the workmen principally applied to the two species which make up the first genus of that class, called by Dr. Hill the *pholides*. These are the Montmartre kind, and that of Derbyshire. See Pholis.

The first of these, or *parget* of Montmartre, is dug in the place from whence it has its name, and is very pure; of a considerably bright and glossy appearance: when fresh broken, of a close, firm, and compact texture, and somewhat soft and smooth to the touch. It is found in masses of different sizes, from four inches to as many feet in diameter; and of no determinate shape or figure, but usually somewhat flatted. It is usually of a pure and fine white, tho' sometimes a little brownish; and in both cases so exactly resembles in structure and appearance, a lump either of coarser or finer loaf sugar, as not to be easily distinguished from it at sight. When broken, it looks considerably bright, and is seen to be composed of small flat particles laid together with no order or regularity. It will not give fire with steel, nor ferment with aqua fortis; but very freely calcines to a fine white powder, the uses of which are well known. We have none of this kind in England. *Hill's* Hist. of Foss. p. 112.

The Derbyshire *parget* of this genus, (for there are many of the others dug in the same county, which are much less valuable) the *pholis* of that country, as it ought distinctly to be called, which is what our workmen distinguish by the name of *Derbyshire parget*, of all the gypsums comes the nearest the nature of the French. This is distinguished from all the other English gypsums by its superior hardness, its brightness, and the breadth of its constituent particles. It is of an extremely irregular, rough, coarse, and unequal texture, and is not at all soft to the touch. It is very beautifully variegated in colour with a fine bright white, and a dusky pale red. The white is usually the ground, and the red is disposed in form of clouds, spots, or veins in it. It is found in broad flat masses of uneven and rugged surfaces; some of these are four or five feet in breadth, and two or three in thickness.

These are of a dusky surface, but very bright and shining when broken, and its construction is very irregular; some parts of it, where the broad faces of its flakes are seen, appearing of a foliaceous structure, and others, where their egdes come in view, of a striated one. Its constituent particles are scaly, but longer and narrower than those of the French kind. It is much heavier than the French kind, and will neither give fire with steel, nor ferment with acids; and calcines a little more slowly than the other to a white plaister. This is dug in vast quantities in Derbyshire, in Yorkshire, and some other parts of England. *Hill's* Hist. of Foss. p. 113.

PARHELIUM *(Cycl.)*—The frequent appearances of *parhelia* in cold climates, seem to confirm Descartes's hypothesis, of their proceeding from icy particles suspended in the air. See Phil. Trans. N° 465. Sect. 2.

PARHOMOLOGY, Παρομολογια, in rhetoric, a figure wherein part is yielded to the opponent, and the rest denied: thus, *Sume hoc ab judicibus nostrâ voluntate: neminem illi propiorem cognatum, quam te, fuisse, concedimus: officia tua nonnulla in illum extitisse, stipendia vos unâ fecisse aliquamdiu, nemo negat sed quid contra testamentum dicis, in quo scriptus hic est.* *Voss.* Rhet. l. 5. p. 389. See Concession, *Cycl.*

PARIETALIA *ossa*. These are situated on the superior, lateral, and a little on the posterior parts of the skull. They are of a larger extent than any other bone of the skull; and their figure is nearly that of an irregular convex square. They have each an external and convex side, and an internal and concave one, four edges, one superior or sagittal, one inferior or temporal, one anterior or frontal, and one posterior or occipital. The superior edge is the longest; the inferior the shortest; in this last there is a very large squamose slope, which may be properly named the temporal slope; the upper and posterior edges are indented thro' their whole length; the anterior edge is indented also, except at its lower part; and all the lower edge is squammous, except a small portion next the os occipitis. It has four angles, the anterior and upper, the anterior and lower; the posterior and upper, and the posterior and lower: the anterior and lower angle ends in a squammous production, which from it situation may be called the *temporal angle*, or *apophysis*. On the outside above the temporal slope, is seen the most considerable portion of the semi-circular plane of the temporal muscle; near the upper edge toward the posterior angle, is a small hole called the *parietal hole*, which is sometimes found only in one of the bones, sometimes in the sagittal suture, and in some subjects is intirely wanting. In some this hole also goes only to the diploe, in others it perforates both tables.

These bones are the weakest of all the eight that compose the skull. The diploe is found between the tables thro' the whole length of the sagittal and occipital edges, and thro' the upper half of the coronal suture. These bones contain a large portion of the brain, form part of the temples, and serve for the insertion of the temporal muscles. *Winslow's* Anatomy, p. 24.

PARIETARIA, *pellitory of the wall*, in botany, the name of a genus of plants, the characters of which are these: The flower is of the apetalous kind, and consists usually of only four stamina, which arise out of a cup divided into four segments. This is sometimes of the bell-shape, sometimes of the funnel-shape, and sometimes rotated. The pistil finally becomes an oblong seed, which is contained in the cup of the flower.

The species of *parietaria*, enumerated by Mr. Tournefort, are these: 1. The common *parietaria*, or *pellitory of the wall*. 2. The Basil-leaved *parietaria*. 3. The least annual Portugal *parietaria*. *Tourn* Inst. p 509.

This is a plant of a long time famous in medicine. It is cooling and abstergent. It is prescribed in stranguries, and in cases of gravel or small stones in the kidneys; and is an ingredient in many of the shop-compositions, intended for those purposes. It is sometimes made an ingredient in decoctions for clysters, to be given in nephretic cases, and externally is much recommended in the erysipelas, and for the softening of hard tumors.

PARISTHIMA, a word used by some authors to express the tonsils. See Tonsils.

PARIUM *marmor*, in the natural history of the antients, the white marble used then, and to this day, for carving statues, &c. and called by us at this time *statuary marble*.

Too many of the later writers have confounded all the white marbles under the name of the *parian*; and among the workmen, this and all the other white marbles have the common name of *alabasters*; so that it is in general forgotten among them, that there is such a thing as alabaster different from marble; which, however, is truly the case. Almost all the world also have confounded the Carrara marble with this, tho' they are really very different; the Carrara kind being of a finer structure and clearer white than the *Parian*, but less bright and splendid, harder to cut, and not capable of so glittering a polish.

The true *Parian* marble has usually somewhat of a faint blueish tinge among the white, and often has blue veins in different parts of it. It is supposed by some to have had its name from the island Paros, one of the cyclades in the Ægean sea, where it was first found; but others will have it to have been so called from Agoracritus Parius, a famous statuary, who ennobled it by cutting a statue of a Venus in it. *Hill's* Hist. of Foss. p. 462.

PARK *(Cycl.)*—A *park* ought to have three sorts of ground in it: 1. Mountainous and barren. 2. Hilly and yet fertile. And 3. Plains that are sufficiently fruitful. The mountainous part should be well covered with high woods over at least a third part of it. The downs and hilly part should have one third part coppices and low woods; and the plains should be at least one third part pasture ground, with some arable or corn land. There should be a river contrived to run thro' some part of it, and a spring or brook to go through a great part, and at length fall into the river.

These are the natural advantages to be wished in a *park*; but when they are wanting, they are to be supplied as far as may be by art, as by ponds to preserve rain water, to supply the place of rivers and springs and proper plantations, and exposures for the rest; only the person who is to make a *park* should know what the natural advantages are, that he may take in as many of them as he can. When ponds are to be made to supply the place of natural brooks and rivers, they should be made large enough; the extraordinary expence in this will be easily repaid, by breeding fish in them, and fowl may also be kept in plenty on them. The *park* should also be well stored with trees; oaks should not be wanting in it; but beech and chesnut are the quickest of growth, and are easy to be had: these, therefore, should be planted in considerable numbers. Apple-trees and plum-trees also should be planted, as generally thriving very well, and affording good food to the deer, &c.

The best inclosure for a *park* is a brick or stone wall; but as the expence of this is very great, it may be done by paling; the pales must, in this case, be of sound heart of oak; and so close planted, that no animal of prey can make its way in between them; and for a farther defence, a good-quick set hedge is very proper, and should be kept in good order. Some part of the mountain and high wood, may conveniently be made a heronry, and some part of the

middle may be a warren for hares and rabbits. Colts and horfes may be bred at large in the *park*, and in the fummer feafon it will be proper to have cows in the pafture ground on the plains.

There fhould be at leaft five or fix enclofures in the *park*, that the deer may be fhut out or let in as occafion requires. In the coldeft feafons they fhould always be kept altogether in the high woods, where they have good fhelter, and are to be fed conftantly with provender by the keepers. In the fummer fuch a number as are intended to be ufed may alfo be kept on the beft ground, that they may thrive quicker than thofe intended only for ftore. Some artificial holes and caverns fhould alfo be made for the deer to retire into in the hot weather, as well as in the cold.

PARK-*bote*, in our old writers, fignifies to be quit of inclofing a *park* or any part thereof. 4 Inft. 308. *Blount.*

PARKINSONIA, in botany, the name of a genus of plants, fo called in honour of the Englifh botanift, Parkinfon. The characters are thefe: the perianthum is deciduous, and is formed of one leaf divided into five fegments at the edge. The flower is compofed of five petals, nearly equal in fize, and larger than the fegments of the cup. They are difpofed in a circular form, and the four uppermoft are oval, the under one kidney-fhaped. The ftamina are two filaments, fomewhat crooked; the antheræ are oblong; the germen of the piftil is oblong, flender, and fomewhat bent; there is fcarce any ftyle; the ftigma is oblate and affurgent. The fruit is an extremely long pod, of a cylindric figure, and fwelling out in the places where the feeds are, fo that it looks like a necklace. The pod terminates in a point, and contains as many round feeds as there are protuberances on it. *Linnæi* Gen. Pl. p. 179. *Plum.* Gen. 3.

PARLIAMENT (*Cycl.*)—From the inquiries and reafonings of our antiquarians, it feems there has always been fomething of the nature of a *parliamentary* affembly, as antient as any thing we know of our conftitution. This affembly was fometimes called *magnates regni, omnes regni nobiles, proceres et fideles regni, difcretio totius regni, generale concilium regni. Spelm.* Gloff. voc. *Parliament. Prynn*'s Rights of Commons, 99.

But tho' this in general feems fettled, yet many have been the difputes of antiquaries, with refpect to the power and authority of thefe affemblies; as alfo about the perfons who compofed them. The firft formation of the houfe of commons has been particularly the fubject of warm debates.

Cambden, in his *Britannia* [a], dates the original of the houfe of commons, as now elected, from the 39th of Henry III. and fays he has it *ex fatis antiquo fcriptore*, but does not name his author. Pryn, in his plea for the lords, follows him [b]; and fo do Dugdale, Heylin, Brady, Filmer, and others. Among other reafons this is one, that the firft writ of fummons of any knights, citizens and burgeffes, now extant, is no antienter than the 49th of Henry III. and it feems the moft probable, and moft commonly received opinion, that the houfe of commons was eftablifhed during the reign of Henry III. after he had vanquifhed the barons. Before that it is fcarce credible they would have fuffered any power in oppofition to their own. Thus much is certain, that in the reign of Edward I. we find a houfe of lords, and alfo a houfe of commons, confifting of knights, citizens, and burgeffes. [[a] *Cambd.* p. 13. [b] Pryn. l. c. p. 182.]

Sir Edward Coke, in his fourth inftitute [a], fays, that the lords and commons at firft fate together. Whether they did or did not, does not well appear, nor does Selden [b] determine the point. [[a] p. 2. [b] Tit. of Hon. 704.]

The parliament commences by the king's writ or fummons: antiently fome of the peers only were fummoned, as it might have often proved inconvenient to fummon them all, if it be true that they were once about 3000 in number [a]. When a parliamentary peerage was eftablifhed, all were fummoned: hence my lord Coke fays [b], that every lord, fpiritual and temporal, of full age, ought to have a writ of fummons *ex debito juftitiæ*. [[a] Vid. *Spelm.* Gloff. 67. *Seld* Tit. of Hon. 692. [b] 4 Inft. 1. For the form of fuch fummons, fee *Cotton*'s Records, 3, 4.]

Antiently the tenure firft created the honour, and fuch as held *per baroniam* were fummoned to do fuit and fervice in parliament; and as fuch a fummons was an evidence of the tenure, fo it has been fince fettled, that the fummons and fitting in parliament makes the baron. But in all degrees of quality above a baron, a fummons is not fufficient; becaufe there are other ceremonies requifite, which muft be performed, unlefs difpenfed with by letters patent; and thefe being matters of record muft be produced [a]. [[a] *Seld.* Tit. of Hon. 495, 530. *Show.* P. C. 5. *Spelm.* Glofs 142.]

The firft fummons of a peer to *parliament* differs from an ordinary fummons, becaufe in the firft fummons he is called up by his proper chriftian and furnames, not having the name and title of dignity in him till he has fat; but after that, the name of dignity becomes part of his name: but the writ of creation, in all other things, is the fame with the ordinary writ that calls him. *Co. Litt.* 16.

The writ of fummons iffues out of chancery, and recites, that the king *de avifamento concilii*, refolving to have a *parliament*, defires *quod interfitis cum*, &c. Each lord of *parliament* is to have a diftinct fummons, and each fummons is to iffue at leaft forty days before the parliament begins. Vid. 7 and 8 of *Will.* and *Mar.* c. 25.

Of the manner of fummoning the judges, barons of the exchequer, king's council, and civilians, mafters in chancery, who have no voices, and how the writs differ from that to a lord of *parliament*, Vide Reg. 261. F. N. B. 229. 4 Inft. 4.

Alfo a writ of fummons muft be directed to every fheriff of every county in England and Wales, for the choice and election of knights, citizens, and burgeffes, within each of their refpective counties [a]. [[a] 4 Inft. 6. 10. *Co. Litt.* 109. Vid. 7 and 8 *Will.* and *Mar.* c. 25.]

So a writ of fummons muft iffue out to the lord warden of the cinqueports, for the elections of the barons for the fame; who in law are burgeffes. 4 Inft. 6.

The fubftance of thofe writs ought to continue in their original effence, without any alteration or addition, unlefs it be by act of *parliament*. 4 Inft. 10.

At the return of the writ, the *parliament* cannot begin but by the royal prefence of the king, either in perfon or by reprefentation: by reprefentation two ways; either by a guardian of England by letters patent under the great feal, when the king is out of the realm, or by commiffion under the great feal of England to certain lords of *parliament*, reprefenting the perfon of the king, he being within the realm, in refpect of fome infirmity. 4 Inft. 6.

Every lord fpiritual and temporal, and every knight, citizen, and burgefs, fhall, upon fummons, come to the *parliament*, except he can reafonably and honeftly excufe himfelf; or he fhall be amerced. That is, refpectively, a lord by the lords, and one of the commons by the commons. 4 Inft. 43, 44.

If any member of the houfe of commons votes, or fits there during any debate, after the fpeaker is chofen, without having firft taken the oaths of allegiance and fupremacy, &c. between the hours of nine and four, in full houfe, he fhall be adjudged a popifh recufant convict, be incapable of any office, and fhall forfeit 500l. Stat. 30. *Car.* II. c. 1. But fee 1 *Will* and *Mar.* by which the form of the oath is altered; and 13 and 14 *Will.* III. which enjoins the abjuration oath, with like penalties, which is altered in its form by 4 *Ann.* c. 5.

The rights and qualifications of elections depend for the moft part on feveral acts of *parliament*. But it is to be obferved, that the rights and qualifications of voters in cities, towns, and boroughs, depend on their charters, and fuch cuftoms as have prevailed in them time immemorial. *Hobart.* 120, 126, 141.

The 2 Geo. II. c. 24, was made for the better afcertaining in general the right of voting, and for the greater fecurity of returning officers.

Antiently the manner of proceeding in bills was very different from what it is at this day: formerly the bill was in the nature of a petition, and thefe petitions were entered upon the lords rolls; upon thefe rolls the royal affent was likewife entered; and upon this, as a ground work, the judges ufed, at the end of the parliament, to draw up the act into the form of the ftatute, which was afterwards entered upon the rolls called the *ftatute rolls*: this was different from thofe called the *lords rolls*, or the rolls of *parliament*. Upon thefe *ftatute rolls*, neither the bill, nor the petition from the commons, nor the anfwer of the lords, nor the royal affent, was entered; but only the ftatute, as it was drawn up and penned by the judges. This was the method till about Henry Vth's time; but then it was defired, that the acts of *parliament* might be drawn up and penned by the judges before the end of the *parliament*; by reafon of a complaint then made, that the ftatutes were not equally and fairly drawn up and worded. After the *parliament* was diffolved or prorogued in Henry VIth's time, the former method was altered; and then bills *continentes formam actus parliamenti*, were firft brought into the houfe. Thefe bills, before they were brought into the houfe, were ready drawn in form of an act of *parliament*, and not in the form of a petition, as before: upon which bills it was written by the commons, *foit baile al feigneurs*; and by the lords, *foit baile al roy*; and by the king, *le roy le voit*. The bill thus endorfed, was to remain with the clerk of the *parliament*, and he was to enter the bill thus drawn at firft in the form of an act of *parliament*, or ftatute, upon the *ftatute rolls*, without entering the anfwer of the king, lords, or commons; and then he iffued writs to the fheriffs, with tranfcripts of thefe *ftatute rolls*, to proclaim the ftatute.

To the paffing of a bill the affent of the knights, citizens, and burgeffes muft be in perfon; but the lords may give their votes by proxy: and the reafon hereof is, that the barons did always fit in *parliament* in their own right, as part of the *pares curtis* of the king; and therefore, as they were allowed to ferve by proxy in the wars, fo they had leave to make their proxies in *parliament*; but the commons coming only as reprefenting the *barones minores*, and the focage tenants in the county, and the citizens and burgeffes as reprefenting the men of their cities and boroughs, they could not conftitute proxies, becaufe they themfelves were but proxies and reprefentatives

of others, and therefore could not constitute a proxy in their place; according to that maxim of law, *delegata potestas non potest delegari*. 4 Inst. 12.

Both houses must be prorogued together, and dissolved together; for one cannot subsist without the other [a]. [a Sir *Robert Atkin*'s argument.]

PARNASSIA, in botany, the name of a genus of plants, the characters of which are these: 1. The flower is of the rosaceous kind, being composed of several petals, some large and others smaller, fimbriated and arranged in a circular form. The pistil arises from the cup, and finally becomes a membranaceous fruit of an oval figure, unicapsular, and containing small seeds affixed to a four-fold placenta. There is only one known species of this plant. See Tab. 1. of Botany, Class 6. and *Tourn*. Inst. p. 246.

PARNOPS, in natural history, the name of a species of wasp, found very frequently in vineyards, and among the winepresses, especially in hot countries. It is distinguished from all the other wasps by the roundness of its body, which is not slender or flatted in the common way, but round and tumid.

PAROCHETEUSIS, a term used by Hippocrates to express a derivation of the humors from one part, in order to the evacuating them by another not far distant. This is often a very happy turn for the cure of a disease.

PAROCHUS, among the Romans, one who provided mules, tents, and carriages, with all other necessaries, for the provincial magistrates in their journies, as also for ambassadors. For in the early times of the republic, they had their charges borne by the public, that the allies or provincials might not be burthened. *Pitisc*. in voc.

PARONYCHIA, *whitlowgrass*, in botany, the name of a genus of plants, the characters of which are these: the flower has no petals, but is composed of numerous stamina, arising from a cup formed into the shape of a basin and divided into five segments. The pistil finally becomes an orbicular seed, which is contained in a sort of pentangular capsule, which was once the cup of the flower.

The species of *paronychia*, enumerated by Mr. Tournefort, are these: 1. The Spanish *paronychia*, called by some the *white anthyllis*, and *white small knot-grass*. 2. The upright Narbonne *paronychia*. 3. The broad-leaved procumbent *paronychia*. 4. The chickweed-leaved procumbent Spanish *paronychia*, with less compact heads. 5. The shrubby myrrh leaved Spanish *paronychia*. 6. The knotgrass-leaved Portugal *paronychia*, with echinated heads. *Tourn*. Inst. p. 507.

PARRELS, in a ship, are frames made of trucks, ribs, and ropes, which having both their ends fastened to the yards, are so contrived as to go round about the masts, that the yards by their means may go up and down upon the masts. These also, with the breast ropes, fasten the yards to the masts.

PARROT, the English name expressing in general the whole psittacus kind, but appropriated by use to that class only of them, which is of a middle size between the macaw and paroquette.

The common green *parrot* is of this kind, and besides that, there are eleven other known species: 1. The white crested *parrot*. 2. The spotted beaked kind. 3. The black beaked kind. 4. The white headed one. 5. The changeable, or red and blue *parrot*. 6. The blue-grey one, common in our cages. 7. The red and white one. 8. The Ajuracura, or blue and green *parrot* of the Brasils; of which there are two subordinate species beside the common one, the one with a sea-green, and the other with an admixture of black about the head. 9. The paragua, a black *parrot* with a red belly. 10. The tarabe, a green one with a red head. And 11. The ajuracatinga, a *parrot* of considerable size, all over of a beautiful green, except that the beak is white and the legs grey; and of this there is a smaller species, no way different except in size. The four last are Brasilian birds, the rest are natives of both the East and West Indians; but many of them have never been seen amongst us. *Ray*'s onrithology, p. 74, 75, 76.

PARSLEY, *apium*, in botany, &c. See APIUM.

PARSNEP, *pastinacha*, in botany, see PASTINACHA.

The *parsnep* is to be propagated by sowing the seeds in February or March, in a rich mellow soil, which must be deep dug, that the roots may be able to run deep without hindrance.

It is a common practice to sow carrots at the same time, upon the same ground with the *parsneps*; and if the carrots are designed to be drawn young, there is no harm in it. The *parsneps* when they are grown up a little, must be thinned to a foot distance, and carefully kept clear of weeds. They are finest tasted just at the season when the leaves are decayed; and such as are desirous to eat them in spring, should have them taken up in autumn, and preserved in sand. When the seeds are to be saved, some very strong and fine plants should be left for it at four feet distance, and towards the end of August, or in the beginning of September, the seeds will be ripe: they must then be carefully gathered, and dried on a coarse cloth. They should always be sown the spring following, for they do not keep well. *Miller*'s Gard Dict.

The common wild *parsnep* is frequent by road-sides and in dry pastures; it flowers in autumn and ripens its seed soon after.

The seeds deserve to be brought into use in medicine much more than they are at present. They are warm and carminative, tho' not so violently hot as the caraway seeds and others which we commonly use on these occasions. They dispel flatuses, and are in great esteem among the country people for curing the colic. They also are diuretic and aperient, and gently promote the menses.

PART (*Cycl.*)—PART, in the manege, in French *partir*, is used to signify the motion and action of a horse when put on at full speed. From the horse's *parting* to his stop there is commonly two hundred paces of ground. To make your horse *part* with a good grace, you must put your bridle three fingers lower, and press gently with your heels, or only with the calves of your legs. See ECHAPER.

To PART *again*. See REPART.

PART *owners*, those that are concerned in ship matters, and who have joint shares therein.

PARTERRE, (*Cycl.*) in gardening, a level division of ground, which for the most part faces the south, or best front of a house, and is generally furnished with ever greens, flowers, &c. There are two kinds of these, the plain ones and the *parterres* of embroidery.

Plain *parterres* are most valuable in England, because of the firmness of the English grass turf, which is superior to that of any other part of the world; and the *parterres* of embroidery are cut into shell and scroll work, with alleys between them. An oblong, or long square, is accounted the most proper figure for a *parterre*; and a *parterre* should, indeed, be always twice as long as it is broad, because, according to the known laws of perspective, a long square always sinks to a square; and an exact square always appears less than it really is. As to the breadth of a *parterre*, it is to be proportionable to the front of the house; but less than a hundred feet in breadth is too little.

There should be on each side the *parterre* a terras walk raised for a view, and the flat of the *parterre* between the terrases should never be more than three hundred feet, at the utmost, in breadth; and about a hundred and forty feet in width, with twice and a half that in length, is esteemed a very good size and proportion. *Miller*'s Gard. Dict.

PARTHENIUM, in botany, the name given by Linnæus to a large genus of plants, comprehending, beside the *parthenia* commonly so called, the partheniastrum of Nissole and Dillenius, and the hysterophorus and tarchonanthus of the same author, and of Vaillant. The characters of the genus are these: the common cup is very simple, being five leaved and expanded; the leaves of it are roundish, plane and equal; the corolla is compound and convex; the corollulæ or semifloscules are very numerous; and the hermaphrodite ones are placed in the center. The female ones are only five in number; they are placed in the verge or radius, and scarce exceed the others in length. The hermaphrodite flowers are monopetalous, tubulose, and erect; the rim divided into five segments, and of the length of the cup. The female ones are monopetalous and tubulose, but they are flatted at the end, obtuse, and roundish, and of the same length with the hermaphrodite ones. In the hermaphrodite flowers there are five capillary filaments serving as stamina; these are of the length of the flower, and the antheræ are thick and almost loose. In the hermaphrodite flowers the pistil has a germen placed under the cup, and so small as to be scarce visible; the style is very slender, and shorter than the stamina, and it has no stigma. In the female flowers the germen of the pistil is turbinated and cordated at the end, and is naked and of a compressed figure; the style is capillary and of the flower's length; there are on this two capillary stigmata of the same kind, and opening at their tops. There is no other fruit but the cup, which remains upon the plant unaltered. The seed in the hemaphrodite flowers is abortive, and in the female, remains in the cup and is single, of a turbinated form, cordated at the extremity, and compressed. The flowers are so disposed in the head, that every female has two hermaphrodite ones at its back. *Linnæi* Gen. Pl p. 455. *Nissole*, A. G. 1711. *Dillen*. Gen. 13. Hort. Elth. 22. *Vaillant*, A. G. 1720. p. 1719.
